You are dispatched to a rural hospital intensive care unit (ICU) for an emergency transfer to a tertiary hospital facility located approximately 90 miles away. En route to the transferring hospital, dispatch relays the following limited patient information. Your patient is a 37-year-old male with a past medical history of a kidney transplantation requiring lifelong treatment with immunosuppressant medications. He presented to the rural hospital emergency department 2 days ago with a fever of 102.2°F (39°C) and a mild nonproductive cough. He was diagnosed with COVID-19 following a positive reverse transcriptase polymerase chain reaction (PCR) result for SARS-CoV-2. The patient was admitted for observation to a general medical floor bed; however, last night he was transferred to the ICU and intubated for respiratory failure. The patient weighs 248 pounds (112 kg) and is 5 feet 10 inches tall. The patient is being transferred to the tertiary hospital for consideration of initiating veno-venous extracorporeal membrane oxygenation (V-V ECMO). Air transport is not available due to inclement weather. Once at the referring hospital, you anticipate a ground transport time of approximately 2 hours to the receiving facility.

On your arrival to the referring hospital ICU, you find a staff nurse and the referring physician at the patient's bedside. Both are dressed in full PPE and are attempting to suction the patient's endotracheal tube with assistance from the respiratory therapist. You and your partner note the droplet precaution signage posted on the patient's door and the isolation cart placed outside the patient's room.

After you and your partner don the appropriate PPE (gown, N95 mask, full-face shield, and gloves), the referring physician reports to you that the patient has been admitted for approximately 48 hours and has severely decompensated during that time. In the emergency department, his chest radiograph was normal; however, he was admitted to the hospital for observation given his immunosuppressed state and a new 2 L/min low-flow nasal cannula oxygen requirement. During the first 24 hours, the patient was maintaining his oxygen saturation on low-flow nasal cannula. He has been treated with IV dexamethasone daily. However, in the past 24 hours the patient complained of increasing shortness of breath and developed gradually worsening hypoxia, requiring the use of high-flow nasal cannula oxygen and a trial of awake prone positioning. A repeat chest radiograph last night showed extensive bilateral air space consolidations consistent with multifocal pneumonia. The patient was intubated early this morning for worsening hypoxic respiratory failure and increasing agitation using rapid-sequence intubation medications. The intubation was extremely challenging, requiring three attempts and the use of a hyperangulated video laryngoscopy blade.

In addition to his history of a kidney transplantation 7 years ago, the patient has a history of type 2 diabetes mellitus, hypertension, gastroesophageal reflux disease, and depression. He has no known drug allergies, smokes occasional marijuana, and drinks three to four beers per week. According to the patient's wife, he is compliant with his daily prescription regimen for his kidney transplant but does not like taking his other medications.

Your initial assessment of this patient reveals that he awakens briefly, for less than 10 seconds, to voice, which is consistent with a Richmond Agitation and Sedation Scale (RASS) score of negative 2. The patient appears comfortable and adequately sedated on a continuous fentanyl infusion at 100 μg/h IV (0.9 μg/kg/h) and midazolam 4 mg/h IV (36 μg/kg/h). His airway is secured with an 8.0 endotracheal tube at the 24-cm mark (teeth). The patient is being ventilated with synchronized intermittent mandatory ventilation (SIMV) with the following settings:

- Tidal volume: 440 mL (6 mL/kg based on a predicted ideal body weight of 73 kg)
- Rate: 24 breaths per minute
- Positive end-expiratory pressure (PEEP): 10 cm H_2O
- FIO_2: 1.0
- Pressure support: 10 cm H_2O

The patient has a right internal jugular vein triple-lumen central line catheter in place and two peripheral IV lines in his bilateral antecubital fossa. The fentanyl and midazolam drips are infusing via the central line catheter, and normal saline is infusing at 150 mL/h in the right antecubital fossa peripheral IV. The second of two units of convalescent plasma has just finished infusing in the left antecubital peripheral IV. Prior to placing the transport monitoring equipment on this patient, the following vital signs are noted on the patient's ICU monitor: ECG, sinus tachycardia with occasional unifocal premature ventricular contractions; heart rate, 118–126 beats/min; blood pressure, 104/62 mm Hg; respiratory rate, 24 (SIMV); SpO_2, 83%; $ETCO_2$, 54 mm Hg; and rectal temperature, 101°F (33.3°C).

When you receive the transfer chart, you note the following laboratory values and radiology reports: WBC count, 17,000/mm^3; BUN, 66 mg/dL; creatinine, 3.3 mg/dL; Na+, 133 mEq/L; K+, 5.0 mEq/L; Cl^-, 104 mEq/L; glucose, 262 mg/dL; D-dimer, 1.6 mg/L; pH, 7.26; PCO_2, 62 mm Hg; PaO_2, 50 mm Hg; and Hco_3^-, 22 mEq/L. Blood cultures show no growth to date, and a urinalysis is negative for infection. You verify on the patient's PCR that he is positive for SARS-CoV-2 and negative for influenza A and B. A CT scan performed this morning was negative for acute pulmonary embolism but did show bilateral multifocal ground-glass opacities, with notable consolidation in the bilateral lung bases consistent with COVID-19 pneumonia.

On completion of your assessment of this patient, you note the following findings. His skin is “hot” to the touch, dry, and pale. His pupils are equal and reactive to light at 3 mm. The trachea is midline, with no evidence of jugular venous distention. The remainder of the head/eyes/ears/note/throat examination is within normal limits for this patient. The chest wall has an equal symmetric rise and fall that is synchronous with mechanical ventilations. The breath sounds reveal bilateral coarse rhonchi, and the abdomen is soft with no distention noted. The pelvis is within normal limits, with an indwelling urinary catheter that provides for gravity drainage. There is no swelling, redness, or signs of infiltration noted with the central line or peripherally inserted IV lines.

Before you move the patient to the transport stretcher, your partner transfers the fentanyl, midazolam, and normal saline infusions to your transport pumps. The patient is placed on your unit transport monitor, with the ECG, SpO_2, $ETCO_2$ and noninvasive blood pressure alarms on and functioning. The patient remains on the hospital ventilator while your partner replicates the ventilator settings from the referring hospital. You then move the patient to your stretcher without incident as the transport ventilator is attached (alarms are on and functioning).

You depart the ICU with the transfer documentation and radiology studies to your awaiting ground unit. The patient is loaded and secured with all power and oxygen requirements transferred to the ground unit source. You depart the referral hospital and head to the receiving facility with routine traffic due to the weather conditions.

While en route to the receiving hospital, the patient’s condition remains the same without any change in his hemodynamic or neurologic status. The SpO_2 remains in the range of 82% to 86% on the transport ventilator despite an FIO_2 of 1.0 and increasing his PEEP from 10 to 12 cm H_2O. Your partner contacts your dispatch center to relay an updated report and an estimated time of arrival to the receiving hospital. No orders are received from the receiving facility. You will be following your standing protocols for this patient’s care.

1. When transporting a patient with a highly infectious disease, what procedural steps can you take to protect yourself, your partner, other health care workers, and bystanders from exposure?
2. When transporting a patient with a highly infectious disease, what equipment can be utilized to protect yourself, your partner, other health care workers, and bystanders from exposure?

Analysis

This is a complex scenario involving COVID-19 and severe acute respiratory distress syndrome (ARDS) in an immunosuppressed patient. Safe transportation of critically ill patients is always challenging; however, the COVID-19 pandemic has frequently highlighted some important considerations when transporting patients with a highly contagious disease. In this scenario, you must successfully manage the tenuous oxygenation and ventilation status of a patient in fulminant ARDS while also controlling for potential viral transmission. Careful execution of infection control measures to minimize nosocomial spread to other patients, health care workers, and bystanders is mission critical. Haphazard transportation resulting in breaches in infection control practices can compromise your health and that of countless others long after the transportation is complete.

The following interventions are infection control practices commonly used for the transport of patients with COVID-19. Many of these precautions are also directly applicable to the transport of other highly contagious infectious diseases:

- The transfer center should coordinate the timing of transport and the final location of patient placement within the receiving hospital to minimize use of and potential unnecessary contamination of holding areas.
- You should coordinate the route of transport within the hospital (eg, from ICU to ambulance bay or helipad) with infection control and public relation officers/hospital security. Ensure that the transport route is clear of bystanders and other nonessential staff before patient movement begins.
- Limit the number of personnel for patient transport as much as possible.
- Isolate the ambulance driver from the patient compartment and keep pass-through doors and windows tightly shut.
- When possible, use vehicles that have isolated driver and patient compartments that can provide separate ventilation to each area.
- If a vehicle without an isolated driver compartment and ventilation must be used, open the outside air vents in the driver area and turn the rear exhaust ventilation fans to the highest setting to create a pressure gradient toward the patient area.
- Before entering the driver’s compartment, the driver (if involved in direct patient care) should remove their gown, gloves, and eye protection and perform hand hygiene to avoid soiling the compartment. They should continue to wear their respirator.
- Use single-use disposable or sterilizable medical equipment as much as possible (eg, intubation equipment).
- Wrap nondisposable transport equipment in transparent covers whenever possible. Ensure functionality of the wrapped transport equipment after attaching it to the patient.
- Use infusion pumps with extended tubing when available.
- When available and tolerated by the patient, use biocontainment measures (eg, IsoPod, IsoArk, plastic transparent patient drapes).
- Intubated patients should have a high-efficiency particulate absorbing (HEPA) filter inserted between the patient and the bag-mask device.
- A HEPA filter can also be placed on ventilators just prior to the exhalation valve to prevent unfiltered expired gases from entering the transport vehicle.
- Nonintubated patients should don a surgical face mask in addition to other biocontainment efforts.
- Ensure use of a closed suction system.
- The transport team should don appropriate PPE (N95 mask or higher-level respirator, gloves, gown, and full-face shield) outside the patient room before beginning transport.
- The transport team must adhere to contact/droplet precautions throughout the transport.

- During transport, confirm that closed-loop communication can be conducted between all team members to ensure medical care and proper infection control practices are completed.
- Limit use of aerosol-generating procedures during transport. If possible, discontinue these procedures prior to entering the receiving facility or communicate clearly prior to arrival that these procedures are being performed.
- After transporting the patient, leave the rear doors of the transport vehicle open to allow for enough air changes to remove potentially infectious particles. The time needed to complete transfer of patient care and all documentation at the receiving facility should allow enough time for this to occur.
- After patient delivery to the designated COVID-19 unit, remove all protective equipment coverings.
- Doff PPE in the nearby designated area, taking care not to self-contaminate. An observer is recommended to overlook donning and doffing of PPE when possible.
- Perform hand hygiene immediately after transfer of patient care and doffing of PPE.
- Wear new PPE for the return trip to the station.
- Return all transport equipment to the station by the same ambulance for decontamination.
- When cleaning the vehicle, personnel should wear a disposable gown and gloves, as well as their respirator or face mask. A face shield or goggles should also be worn if splashes or sprays during cleaning are anticipated.
- Decontaminate the transport vehicle in accordance with standard operating procedures. All surfaces that may have come in contact with the patient or materials that became contaminated during patient care (eg, stretcher, rails, control panels, floors, walls, work surfaces) should be thoroughly cleaned and disinfected using an EPA-registered hospital-grade disinfectant in accordance with the product label.

PREP KIT

Ready for Review

- The immune system protects the human body from infection, and removes cells that are past the end of their life cycle, abnormal cells (eg, cancer cells), and damaged cells. While the function of the immune system is to protect against infection, it is also capable of causing damage.
- Better knowledge of diseases and how they spread, consistent use of personal protective equipment (PPE), and a mix of appropriate responder behaviors and organizational policies can improve the safety of health care providers.
- An understanding of infectious disease, the ways in which the body responds to disease, and the methods used to reduce the spread of disease will help CCTPs keep themselves and their families, coworkers, and communities safe.
- For an organism to contract a disease, the host must be susceptible. Susceptibility is determined by factors such as nutritional status, immune status, genetic makeup, living conditions, and exposure.
- The transmission of disease is a complex process. Disease can be transmitted directly through inhalation, ingestion, or direct contact with infectious agents, or indirectly via vectors, fomites (eg, contaminated fluids or equipment), or some other complex cycle of interactions.
- For the immune system to protect the body from invading microorganisms, it must be able to distinguish “self” components from “non-self” components or cells; it must be both highly specific and general; and it must provide protection that consists of several layers so that once one level of immunity has been breached, additional methods of fighting infection remain available.

- Immunity can be either innate (the type of immunity one is born with, which provides protection from invading pathogens despite a lack of prior exposure) or acquired (the type of immunity that develops as a result of interactions between components of the immune system and the invading microbe, which provides improved protection with repeated exposures to specific agents).
- Innate immunity is nonspecific, is activated immediately on invasion, and has no memory. The primary components of innate immunity are the skin, the mucous membranes, and their secretions, which provide mechanical and chemical barriers to invasion.
- Nonspecific factors of the immune system help limit growth of microorganisms within the body. They include cells such as natural killer cells, neutrophils, and macrophages; proteins such as complement or transferrin; and the body’s general responses to invasion with actions such as fever or inflammation.
- Acquired (adaptive) immunity includes both humoral and cell-mediated immunity. Humoral immunity is provided by B cells through the production of antibodies and complement, whereas cell-mediated immunity is provided by T cells.
- Cytokines and macrophages are modulators of both cell-mediated and humoral immunity.
- Adaptive immunity results from the interaction of the agent with the host, is specific, improves with repeated interactions, allows for the development of immunologic memory, and can be either active or passive.
- Active immunity, an ongoing process of developing antibodies and activating T cells in response to invading agents, occurs either when an individual is exposed to microbes through the natural process of infection or when the immune system is artificially stimulated through a vaccine.
- Passive immunity is the process of giving an individual a preformed antibody (from a donor) in the event of an exposure to a pathogen to which the individual has not yet developed immunity.

- Antigens are a complex of proteins and/or sugars that are anchored into the cell membrane and displayed on the cell’s surface. An antigen is recognized by the immune system as either self or non-self; in the latter case, it will induce a humoral or cell-mediated response.
- The immune system includes the central lymphoid organs (the thymus and the bone marrow), which are the site of synthesis and differentiation of immunocompetent cells.
- The peripheral lymphoid organs are where immunocompetency is expressed; they include the spleen, lymph nodes, tonsils, intestinal Peyer patches, and mucosa.
- Lymph nodes are made up of lymphoid tissues located throughout the body as single units or in chains of units; these nodes are especially prominent in the neck, axilla, and groin.
- T lymphocytes mature to express phenotypic markers or clusters of differentiation called CD markers. CD4+ cells (helper T cells) are regulators of the immune system; CD8+ cells (cytotoxic suppressor T cells) kill virus-infected and tumor cells.
- B cells may differentiate into plasma cells that produce specific antibodies on encountering an antigen, or they may become memory cells.
- Antibodies are globulin proteins (immunoglobulins) that react to an antigen. There are five classes of antibodies: IgA, IgM, IgG, IgE, and IgD.
- The humoral (antibody-mediated) response is effective against agents that produce toxins, against bacteria that have polysaccharide capsules, and against some viral infections.
- In the primary immune response, antibodies do not appear until 7 to 10 days after the initial encounter. Upon a second encounter with the same antigen or a closely related antigen, a more rapid secondary response occurs, with antibody being detected in the serum in only 3 to 5 days, and antibody titers being produced that are much higher than those seen in the primary response.

- Cell-mediated immunity plays an important role in defending the host against intracellular infections, such as tuberculosis and gonorrhea, as well as viral infections, fungal infections, parasites, and tumors.
- Phagocytosis is performed by macrophages, neutrophils, and monocytes, which engulf and destroy bacteria, foreign antigens, and cellular debris.
- The targets of monoclonal antibodies can be a plasma protein, an IgG receptor, or an infectious organism. These therapies can be used to treat hematologic malignancies, solid tumors, autoimmune disorders, hypercholesterolemia, inflammatory bowel disorder, or even a drug overdose (digitalis overdose).
- An inappropriate or exaggerated immune response known as hypersensitivity (allergic) reaction occurs when a first encounter sensitizes an individual to an antigen and induces an antibody response, and then subsequent encounters with the same or a closely related antigen elicit the allergic response.
- Four major types of hypersensitivity reactions are distinguished: Types I, II, and III are antibody-mediated responses, whereas type IV is a cell-mediated response.
- Anaphylaxis is a serious allergic reaction that features a rapid onset of symptoms, has a variable clinical presentation, and, if unrecognized, can lead to respiratory arrest, circulatory collapse, and death. Common triggers for anaphylaxis include foods, drugs, antibiotics, and *Hymenoptera* venom.
- Most cases of anaphylaxis have cutaneous involvement, including flushing, itching, urticaria, or angioedema. Upper airway involvement may include changes in phonation, the sensation of throat closure or choking, cough, wheezing, and shortness of breath.
- The treatments for anaphylaxis focus on early recognition and the use of epinephrine to prevent progression to life-threatening symptoms. Airway management—including intubation, if

necessary—and fluid resuscitation are key components of care for a patient experiencing anaphylaxis.

- In biphasic anaphylaxis, the initial resolution of symptoms is followed by a reappearance of symptoms that, if not anticipated, can pose a life threat.
- Immunodeficiency occurs when one or more of the components of the immune system become damaged or are nonfunctioning as the result of illness or lack of functioning immune cells, or when the immune system is intentionally suppressed by various immunosuppressant therapies.
- Critically ill patients have few reserves to fight infections as the result of a decrease in their host defenses and a loss of innate immunity.
- Features of chronic illness that decrease innate immunity include stress, malnutrition, invasive procedures, loss of physical barriers of skin and mucosal surfaces, and pathogenic bacterial overgrowth or bacterial growth in normally sterile tissue.
- Management of illnesses and injuries during transport of a transplant patient may be complicated by the side effects of immunosuppressive medications (eg, hypertension, hyperglycemia, hyperkalemia, nephrotoxicity, and neurotoxicity) or by the patient’s immunosuppressed condition.
- The body’s normal flora is composed of colonies of nonpathogenic species that assist the immune system by preventing the overgrowth of pathogenic strains by using up available nutrients, maintaining a certain pH level, and creating bacteriocins (antibacterial toxins).
- Many people requiring critical care transport are immunocompromised. CCTPs need to be keenly aware that these very sick patients can be inadvertently infected with opportunistic infections (ie, diseases caused by normally nonpathogenic agents in patients with an abnormally functioning immune system).
- Pathogenic organisms cause disease because they possess unique factors that help them gain entry into the body, colonize

and overcome host defenses, produce toxins that cause cytopathic effects, or do mechanical damage to the body.

- Properties of microbes that influence their virulence (ie, degree of pathogenicity) include host and tissue specificity (the ability of the organism to gain entry into a host), adherence to specific host cells, invasion of host tissue, evasion of host defenses, toxicity, and other characteristics of the pathogen such as antiphagocytic properties.
- Virulence can be experimentally quantified by two measures: ID_{50} and LD_{50}.
- Typical portals of entry into the body for pathogens are broken skin, hair follicles, or sweat glands; the mucous membranes of the respiratory, digestive, and genitourinary tracts; and the conjunctiva of the eye.
- Once inside the body, the pathogenic organism must be able to adhere to specific cells to begin colonization.
- Bacteria are capable of producing two types of toxins: exotoxins, which are produced inside the cell and are released into surrounding tissues or fluids, and endotoxins, which are part of the gram-negative cell wall and are released when the bacteria are destroyed.
- Some organisms produce polysaccharide layers and surround themselves with capsules or slime layers, which protect them against phagocytosis; others form biofilms, which are accumulations of bacteria and other organisms embedded in a matrix of polysaccharide along the surface of tissues.
- Viruses that enter the body bind to host cell surface receptors using viral proteins found on the surface of the virions; the resulting receptor-mediated endocytosis brings the virus directly into the cell.
- Once inside a cell, the virus particle may release its viral nucleic acid, allowing the viral DNA or RNA to direct synthesis of viral-encoded protein and nucleic acid molecules and stimulate the process of new virion assembly.

- Viruses cause illness through three mechanisms: (1) production of viral-specific molecules that deplete the host cell’s resources and lead to eventual cell death; (2) induction of programmed cell death (apoptosis); and (3) induction of large inflammatory responses.
- Epidemiology is the study of how disease is distributed within populations and the factors that influence that distribution.
- The incidence of a disease is the number of new cases of disease within a defined population over a defined period of time.
- The prevalence of a disease is the number of cases of disease detected in a specified period of time, regardless of when the illness was contracted.
- Factors such as the incubation period of a disease or the presence of different carrier states may cause the disease to go undetected in an individual but can place others at risk for contracting the disease. For this reason, CCTPs must use appropriate disease control and prevention practices when providing care to all patients, regardless of whether the patient is currently exhibiting symptoms.
- For a microorganism to infect and reinfect a host, it must have the ability to survive, duplicate or reproduce, and spread to new hosts. Reservoirs of infection provide a supply of nutrients and an environmental niche that support long-term microbial survival.
- Persons who are colonized by pathogenic species but do not have symptoms of the infection (ie, asymptomatic or latent carriers) can serve as sources of infection during extended hospital admissions.
- A reservoir refers to something that leads to the long-term survival of the organism. A broader concept is disease ecology, which refers to the totality of all components of the disease, environment, and host system.
- The health care environment itself may serve as a reservoir of infection. Some organisms can survive on inanimate objects, including durable medical equipment, for an extended duration of time.

- Direct contact involves person-to-person transmission of a pathogen (ie, no intermediate carrier is involved in the transfer).
- Horizontal transmission may occur through sexual transmission, exchange of respiratory droplets or secretions, and transmission by contact.
- Vertical transmission is the exchange of an infectious agent between mother and fetus in utero or during the birthing process.
- Indirect transmission occurs when there is an intervening step in the transmission from reservoir to susceptible host. The intermediate step involves an inanimate object (fomite), such as towels, bedding, thermometers, and contaminated syringes.
- Many infectious diseases are transmitted through the use of a medium such as water, food, air, or contaminated body fluids. Water can be either the reservoir of disease or a vehicle for the transmission of that disease.
- Vector transmission is the movement of a pathogen from an infected organism to a susceptible host via an insect or other animal.
- Meningitis (ie, the inflammation of the leptomeninges) is a serious medical condition that can be caused by bacterial, viral, or fungal infectious agents.
- Bacterial meningitis has an acute onset and is a medical emergency that requires prompt diagnosis and treatment to preserve life and neurologic function. The classic triad of symptoms observed in patients with this disease consists of fever, nuchal rigidity, and altered mental status.
- Most cases of bacterial meningitis are observed in adults and can be caused by a variety of bacterial species, including *Neisseria meningitidis*, *Streptococcus pneumoniae*, and *Haemophilus influenzae*.
- The severity of the symptoms and the disease is less serious with viral meningitis than with bacterial meningitis, and complete recovery can occur in 2 to 7 days without medical intervention.

- Respiratory syncytial virus causes seasonal outbreaks of acute respiratory tract infections.
- The most common cause of cellulitis is beta-hemolytic streptococci, most commonly group A *Streptococcus* or *S pyogenes*; *S aureus* (including methicillin-resistant strains) is a notable but less common cause.
- The vast majority of erysipelas (a specific type of cellulitis) cases are caused by beta-hemolytic streptococci.
- Necrotizing fasciitis is a limb- or life-threatening infection of the soft tissue that affects the subcutaneous tissues, fat, and fascia but usually spares the skin and muscle. Prompt diagnosis and treatment with antibiotics and complete surgical debridement are important to reduce the high mortality rate associated with this disease.
- Epiglottitis (the result of an infected and inflamed epiglottis, aryepiglottic folds, and/or surrounding tissues) can occur at any age. Since the introduction of the Hib vaccine, the incidence of epiglottitis has been drastically reduced in vaccinated children. Because of its severity and rapid progression to airway obstruction as well as the continued infection patterns in adults, CCTPs should be familiar with this disease's clinical presentation and treat patients promptly with empiric antibiotics.
- Tuberculosis (TB) is caused by infection with *Mycobacterium tuberculosis*, which is transmitted via respiratory droplets from the cough of an infected person to the respiratory epithelium of a susceptible person.
- In patients with TB, the first site of infection is the lungs, but the pathogen can also spread to the kidney or spine.
- Most people infected with *M tuberculosis* are asymptomatic. Patients with full-blown pulmonary tuberculosis typically exhibit five symptoms: cough, fever, weight loss, night sweats, and fatigue.
- The emergence of drug-resistant strains of TB has precipitated the use of a multidrug regimen for cure of this disease. The

individual drugs used may vary slightly, but the mainstay of therapy is isoniazid.

- Multidrug-resistant TB is TB that is resistant to at least two of the standard anti-TB medications, isoniazid and rifampin. Limited treatment options are available for patients with this form of the disease.
- When transporting a patient with suspected or known TB, CCTPs should place a mask on the patient (if tolerated) and wear masks themselves.
- CCTPs should comply with yearly purified protein derivative (PPD) testing, which identifies antibodies to TB, to determine their personal history of exposure to TB.
- If care was provided for a patient known to have TB and exposure was a possibility, providers should get a PPD test 6 weeks after that exposure to assess their health status.
- Pneumonia is an infection of the lung parenchyma that may be caused by bacterial, viral, or fungal agents; it is a major cause of death in the United States.
- Many different bacterial species cause pneumonia, including *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Staphylococcus aureus*, *Chlamydia pneumoniae*, and *Legionella pneumoniae*. *Mycoplasma pneumoniae* and viruses cause atypical pneumonias.
- Nosocomial or hospital-acquired pneumonia is a pneumonia that occurs in a hospitalized patient 48 hours or more after admission to the hospital, but that was not apparent at the time of admission.
- Ventilator-associated pneumonia is a type of hospital-acquired pneumonia that occurs in ventilated patients and appears more than 48 hours after endotracheal intubation.
- Health care–associated pneumonia is pneumonia that occurs in nonhospitalized patients who have contact with health care facilities or personnel, such as residents of long-term health care

facilities, patients undergoing hemodialysis, and patients who have had a recent admission to an acute care facility.

- *Pneumocystis jirovecii* pneumonia is a fungal infection that is seen in patients with immunosuppression, such as those taking antirejection therapy for solid-organ transplantation or those infected with HIV. It is included in the list of AIDS-defining illnesses.
- CCTPs should use standard precautions when caring for patients suspected of or diagnosed as having pneumonia. If a patient is coughing, place masks on both the patient (if tolerated) and the CCTP; wear gloves; use good handwashing technique between transports; and clean and decontaminate equipment, including the transport vehicle, prior to undertaking further transports.
- It is especially important to decontaminate equipment such as laryngoscopes and suction equipment after transportation of patients with oral candidiasis (thrush) or patients infected with *P jirovecii.*
- When influenza undergoes a major antigenic drift or a novel combination of hemagglutinin and neuraminidase emerges (antigenic shift), people have little or no antigenic protection from prior infections; pandemics of influenza may then break out and spread quickly.
- Few treatments are available for influenza except supportive therapy; however, when this disease is diagnosed within the first day of symptoms, treatment with an antiviral medication may reduce the severity and duration of symptoms.
- Herpesviruses are noted for their ability to cause latent infections: The acute viral syndrome is followed by a symptom-free period during which the virus is inactive. Reactivation of the virus can occur when the patient is immunosuppressed or through inciting agents.
- Six pathogenic members of the herpesvirus family cause disease in humans: herpes simplex types 1 and 2, varicella zoster virus, cytomegalovirus, Epstein-Barr virus, and human herpesvirus 8.

Epstein-Barr virus and human herpesvirus 8 are associated with the development of Burkitt lymphoma and Kaposi sarcoma, respectively.

- HSV-1 and HSV-2 can cause infection of the fingers with recurring painful blisters, a condition called herpetic whitlow.
- Hepatitis (inflammation of the liver) can be caused by exposure to infectious agents (usually viral), toxins (eg, alcohol), or drugs (eg, acetaminophen). The course of the illness ranges from acute to chronic, and the severity ranges from mild to life threatening.
- Hepatitis A virus (HAV) is usually transmitted via the fecal-oral route, although sexual and parenteral transmissions are possible. Large-scale outbreaks can occur, usually as the result of contamination of food or drinking water.
- HAV infection can be prevented by active immunization with the HAV vaccine or by passive immunization with immune globulin administered before or after a known exposure.
- Hepatitis B virus (HBV) is transmitted through parenteral routes (ie, non-oral transmission). Health care providers are considered an at-risk group for this infection and should receive the HBV vaccine series, with their immunity subsequently being confirmed by titer.
- Unlike HAV, HBV can induce other disease states in addition to causing acute infections—specifically, acute hepatitis, fulminant hepatitis (severe inflammation of the liver, accompanied by rapid destruction of the liver leading to liver failure), and chronic hepatitis (chronic asymptomatic carriers).
- Prevention of HBV infection involves screening the blood supply and removing HBV-contaminated units and donors from the blood donation pool.
- Hepatitis C virus (HCV) is transmitted parenterally through transfusion or IV drug use, through sexual contact with infected people, and from mother to infant. In most cases, acute infection leads to chronic infection, with the disease eventually progressing to hepatitis and fibrotic liver disease (cirrhosis).

- There is no cure for HCV, nor is a vaccine available to prevent infection; the goal of treatment is to prevent the development of cirrhosis and liver failure.
- Hepatitis delta virus (HDV) is transmitted parenterally, but can replicate only with the aid of HBV. All patients with severe HBV infections should be tested for HDV coinfection or superinfection.
- Human immunodeficiency virus causes HIV disease, which in turn can lead to AIDS. This retrovirus infects T lymphocytes and other cells that display the CD4 surface protein and is notable for causing “slow” infections with long incubation periods.
- Transmission of HIV infection occurs through the transfer of infected cells or free virus from one individual to another. Transmission can occur both horizontally (via sexual contact or by exposure to infected blood) and vertically (from mother to neonate across the placenta or during delivery and from an infected mother through breast milk).
- For CCTPs, exposure to patients with HIV infection is a potential risk for disease contraction. Prevention of exposure (eg, through needlesticks) is the most important method of protection for health care workers.
- HIV infection can be divided into two stages: acute infection and chronic infection Chronic HIV infection can be further subdivided into the following stages:
    - Chronic infection, without AIDS
    - AIDS, characterized by a CD4 cell count <200 cells/μL or the presence of any AIDS-defining condition
    - Advanced HIV infection/AIDS, characterized by a CD4 cell count <50 cells/μL
- Antibodies to HIV are not detected in the blood until 3 to 4 weeks after the initial infection. The person is capable of spreading the disease through sexual or blood contacts during this window of time, even though the HIV antibody test result will be negative prior to seroconversion.

- Criteria for the diagnosis of AIDS include HIV infection with a CD4+ helper T cell count of less than 200 cells/μL and/or the presence of an AIDS-defining condition.
- Although an HIV-infected patient might be asymptomatic and symptoms remain latent, the virus continues actively replicating within the lymph nodes.
- Patients with HIV often present many years after the initial infection or acute stage of the disease, because in the initial stages the disease is often mild and the symptoms are nonspecific.
- For many patients with HIV, the illness is noticed when the patient begins to experience symptoms; eventually, loss of cell-mediated immunity predisposes the host to many opportunistic infections.
- In HIV-infected patients, the viral load is estimated by determining how much viral RNA is present in the blood. The viral load indicates the magnitude of HIV replication and its associated rate of CD4 cell destruction. This measurement is the most accurate indicator of the risk for disease progression and is used in planning and monitoring antiretroviral therapy.
- Six classes of antiretroviral drugs are currently used to treat HIV infection: nucleoside analog reverse transcriptase inhibitors, protease inhibitors, non-nucleoside reverse transcriptase inhibitors, integrase strand transfer inhibitors (INSTIs), and the two entry inhibitor classes—CCR5 antagonists and fusion inhibitors.
- The goal of current therapies for HIV infection is to prolong life—by preventing opportunistic infections and malignancies, and slowing the rate of virus production—while maintaining the best possible quality of life.
- Rickettsial diseases are transmitted via tick bite; they include Rocky Mountain spotted fever, ehrlichiosis, and anaplasmosis.
- Rocky Mountain spotted fever should be considered a possible diagnosis in all patients presenting with fever and having suspected or known tick exposure. It begins acutely with fever

accompanied by one or more of the following: headache (usually severe), rash, muscle aches, nausea and vomiting, and malaise. Treatment is with doxycycline (or a similar antibiotic).

- Emerging infectious diseases (diseases whose incidence has increased dramatically in the past 20 years) are particularly damaging to older adults and immunocompromised people, such as those living with HIV disease, those receiving immunosuppressive therapy (eg, recipients of organ transplants), and those who are immunosuppressed as a result of their treatments for cancer.
- Severe acute respiratory syndrome is an emerging lower respiratory tract illness that is associated with high morbidity and mortality.
- Infection with *E coli* O157:H7 may occur after eating undercooked, contaminated ground beef; drinking unpasteurized milk and fruit drinks; eating unwashed lettuce or sprouts; eating salami; swimming in or drinking sewage-contaminated water; or having person-to-person contact.
- West Nile virus is a mosquito-borne pathogen that occasionally leads to meningitis or encephalitis; there is no cure for West Nile virus encephalitis.
- Antibiotics are compounds that are produced by bacteria or fungi that inhibit the growth of bacteriostatic organisms or kill other bacterial organisms (ie, are bactericidal).
- All antibacterial agents follow the same basic principle in their actions: They target bacterial proteins, processes, or cellular components that are not found in human cells.
- The relatively few antiviral treatments available work by interrupting the viral replication cycle at a specific step.
- Antifungal therapies typically bind with components in the fungal cell wall, making the membrane less fluid and more susceptible to rupture, which leads to cell death.
- Almost all important pathogenic bacteria have demonstrated resistance to currently available FDA-approved antibiotics.

- Three important factors that contribute to the emergence of resistant bacteria within a given population or community are misuse use of antibiotics, poor infection control, and importation or intrusion of already resistant strains.
- Antibiotic resistance occurs when bacteria acquire new properties through mutation, protein alteration, or conjugative transfer of plasmid-encoded resistance factors.
- Health care workers are a major source of cross-infection between critically ill patients, and handwashing is the single most important step that they can take to reduce the spread of infection.
- Methicillin-resistant *Staphylococcus aureus* (MRSA) can colonize a variety of tissues, causing infections such as cellulitis, cutaneous abscesses, wound infections, osteomyelitis, septic arthritis, endocarditis, pneumonia, and septicemia.
- High rates of MRSA are found among residents of long-term care facilities, but serious infections with MRSA are more prevalent in the acute care setting.
- Risk factors for colonization with MRSA include dialysis, diabetes, use of injectable drugs, chronic skin conditions such as decubitus ulcers, and a history of prior antibiotic use.
- The emergence of vancomycin-resistant MRSA poses a serious threat to patients and health care workers. Any patient with this type of infection should be isolated, and the infection should be reported to public health authorities.
- Although antibiotic-resistant species of *Enterococcus* rarely cause illness in healthy people, they can cause serious infections in immunocompromised, postoperative, and other seriously ill people.
- When transporting patients infected with vancomycin-resistant enterococci, providers should implement infection control measures such as handwashing, patient isolation, use of protective barriers such as gloves and gowns, and proper disposal of contaminants.

- Knowledge of epidemiologic principles is crucial in differentiating between the presentation of a naturally occurring disease and an unusual, non-natural event that should raise concern that a bioterrorist event has occurred and that local emergency response systems should be activated.
- In bioterrorism scenarios, the CCTP must maintain an index of suspicion regarding a potential threat because early symptoms of exposure may be nonspecific, but early treatment will be required to prevent severe injury or death. Providers must always take steps to protect themselves before approaching patients and should take responsibility for implementing immunologic protection.
- The health risks associated with the CCTP's job are not limited to blood or body fluid exposures; rather, the greatest risk comes from patients who are actively infectious but undiagnosed.
- Steps to reduce exposure risks include using appropriate PPE; properly handling contaminated medical devices; and implementing isolation precautions to control the spread of infection to others.
- The Centers for Disease Control and Prevention recommends that all emergency medical care providers be vaccinated against the following preventable infectious diseases: measles, mumps, rubella, varicella, hepatitis B, influenza (annual), pertussis, tetanus, polio, diphtheria, pneumococcal vaccine, and meningococcal vaccine.
- By law, all needlesticks and other injuries with sharps contaminated by blood must be reported to the CCTP's employer.
- Universal precautions are recommended to prevent transmission of bloodborne pathogens such as HIV and hepatitis B and C; they stipulate use of gloves, gowns, or aprons (or uniforms) and masks or other eye protection to reduce exposure of the skin (especially abraded or broken skin) and mucous membranes.
- After a significant exposure, both the source patient and the health care worker should be tested for baseline values, and the

exposed health care worker should receive follow-up testing at 6 and 12 weeks and at 6 months.

- Standard precautions are used with all patients; they protect against contact with blood, body fluids, and secretions, regardless of the presence of visible blood, and against contact with nonintact skin and mucous membranes.
- Transmission-based precautions are isolation precautions that are designed to be employed during the transport of all patients who have documented infection or who are suspected to be infected with highly transmissible or epidemiologically significant infectious agents.
- Airborne precautions include use of an N95 mask by CCTPs, use of a negative-pressure room (airborne infection isolation room) or transport vehicle, and use of the exhaust fan during transport.
- Droplet precautions include isolation of the patient and use of surgical masks by CCTPs (or keeping at a distance of 3 feet [1 m]).
- Contact precautions include isolation of the patient, use of a gown (or uniform) and gloves, and, if warranted, face protection by CCTPs.
- Clean, nonsterile, disposable gloves are standard equipment on critical care transport units and must be donned by all personnel prior to initiating patient care.
- Masks, face shields, and eye protection are worn to protect the mucous membranes of the eyes, nose, and mouth during procedures and patient care activities that are likely to generate splashes or sprays of blood, body fluids, or excretions.
- Gowns are used to protect the skin and to prevent the soiling of clothing during procedures that are likely to generate splashes of blood or body fluids.
- Proper handling of sharps includes not attempting to bend, remove, or recap needles; not shearing or breaking needles; and disposing of sharps into an appropriate container as soon as possible after use.

- Contaminated work surfaces and all equipment used during the course of the transport must be decontaminated with an EPA-registered disinfectant on completion of the transport.
- Contaminated laundry should be placed into leakproof bags, labeled, and stored until proper disposal is possible. Likewise, regulated waste must be placed in closeable, leakproof containers designed for disposal.
- Do not allow time constraints between transports to deter proper disinfection.
- In case of a blood exposure, wash the area with soap and water, flush the mucous membranes with copious amounts of water, irrigate the eyes with sterile solutions of saline or water, and report the exposure immediately to supervisory personnel and those assigned to manage blood exposure issues.
- Postexposure prophylaxis is available for the prevention of seroconversion after a known exposure to hepatitis B or HIV, but not after exposure to hepatitis C.

Vital Vocabulary

active immunity Production of a specific antibody in response to an infection or antigen.

adaptive immunity The immunity the body develops as part of exposure to an antigen or through vaccination; also called acquired immunity.

anaphylaxis A serious systemic allergic reaction that has a rapid onset and a variable clinical presentation.

antigen An agent that stimulates the formation of specific protective proteins called antibodies.

antigenic drift A series of small genetic changes in a virus that alter the virus just enough that antibodies generated in previous infections no longer recognize the viral epitopes or surface proteins and, therefore, do not protect the body from the symptoms of a new infection.

antigenic shift More drastic genetic changes in a virus, in which the protein structure of one or both of the spike proteins undergoes changes.

apoptosis Programmed cell death.

bactericidal Capable of killing bacteria.

bacteriostatic Capable of inhibiting bacterial growth.

carrier A person or animal that is infected with a disease, but does not express symptoms of that disease.

decontamination Use of chemical, physical, or other means to remove, inactivate, or eradicate harmful microorganisms from people, surfaces, or objects.

dyscrasia In hematology, a disorder of the cellular elements of blood.

endemic A pattern of disease occurrence in which some cases of a disease are always present within a given population, and their numbers are expected and predictable.

endotoxin A toxin that is a structural component of bacterial cells and is not released until the bacteria are destroyed.

epidemic A pattern of disease occurrence in which the number of cases of a disease clearly rises (above a threshold level) in a given time or geographic area.

epidemiology The study of disease distribution within populations and the factors that determine that distribution.

epitope The specific portion of the antigen that is recognized by the antibody or B cell.

etiology The cause of a disease.

exotoxin A toxin produced by a bacterium inside the cell and secreted into surrounding tissues or fluids.

fecal-oral route A route of transmitting infectious organisms from one individual to another; commonly, enteric bacteria or viruses are shed in the feces, spread via contamination of food or water sources, and ingested by other people.

fomite An inanimate object that is capable of transmitting infectious organisms from one individual to another.

health care–associated pneumonia (HCAP) Pneumonia that occurs in nonhospitalized patients who have contact with health care facilities or personnel.

high-level disinfection Treatment used on inanimate objects that kills all microorganisms, but does *not* kill bacterial spores.

hospital-acquired pneumonia (HAP) Pneumonia that occurs in a hospitalized patient 48 hours or more after admission to the hospital, but that was not apparent at the time of admission.

hypersensitivity A reaction consisting of an exaggerated or inappropriate immune response that occurs after a person comes in contact with a substance the body perceives as harmful.

immunity Protection from infection, provided by a complex system of substances, cells, and tissues that exist to protect the human body from infection.

immunocompromised Unable to mount a normal immune response as the result of disease (eg, AIDS), chemotherapy treatment, or certain other medical treatments.

immunodeficiency An abnormal condition in which some part of the body’s immune system is inadequate, such that resistance to infectious disease is decreased.

incidence The number of new cases of a disease within a defined population over a defined period of time.

indicator conditions Rare or unusual diseases associated with an immunocompromised state; also called AIDS-defining diseases.

innate immunity The type of immunity that an individual is born with, such as that provided by the skin and mucous membranes.

intermediate-level disinfection Treatment used on inanimate objects that kills *Mycobacterium tuberculosis,* vegetative bacteria, and most viruses and fungi, but does *not* kill bacterial spores.

isolation precautions Measures taken to prevent contact with pathogens, including airborne, droplet, and contact precautions.

low-level disinfection Treatment used on inanimate objects that kills most bacteria, some viruses, and some fungi, but does *not* kill *Mycobacterium tuberculosis* or bacterial spores.

meningitis An umbrella term referring to five types of inflammation of the leptomeninges, the membranes that cover and enclose the spinal cord and brain.

monoclonal antibodies Antibodies in which large quantities of an antibody from a single B-cell clone are produced to protect against a specific pathogen.

necrotizing fasciitis A limb- or life-threatening infection of the soft tissue that affects the subcutaneous tissues, fat, and fascia.

nosocomial Infections acquired during hospitalization or a nursing home stay.

opsonization The process of making bacterial cells more susceptible to the action of phagocytosis by the action of binding an antibody to the pathogen’s cell membrane.

palpable purpura Relatively large (greater than 3 mm) areas of bleeding under the skin.

pandemic A worldwide epidemic.

passive immunity Short-lived immunity acquired from placental transfer, antibodies in the mother’s milk, or antiserum administered intravenously.

pathogen Any microbe capable of causing a disease state.

petechial lesions Small areas of bleeding under the skin (pinpoint).

phonation The process by which the vocal cords create sound.

plaque-forming unit The number of viral particles capable of forming plaques per a certain volume.

prevalence The total number of cases of a disease within a population, including both old and new cases of the disease.

prodrome Early symptoms indicating the development of disease.

prophylaxis Treatment of disease before it occurs (ie, to prevent the disease).

pruritus Itching.

quiescent A latent state, as occurs with a dormant virus or bacterium, in which an infected patient will exhibit few to no symptoms.

reservoir of infection A host that provides a supply of nutrients and an environmental niche that enable long-term microbial survival.

respiratory syncytial virus (RSV) A labile paramyxovirus that produces a characteristic fusion of human cells in a tissue culture known as the syncytial effect; it can affect both the upper and lower respiratory tracts but is more prevalent with the lower respiratory tract, causing pneumonia and bronchiolitis.

rickettsial diseases Diseases transmitted via tick bite; the three major diseases in this class are Rocky Mountain spotted fever, ehrlichiosis, and anaplasmosis.

seroconversion Development of antibodies, measured in the serum, in response to an infection or vaccine.

severe acute respiratory syndrome (SARS) A highly contagious, potentially life-threatening lower respiratory tract illness that usually starts with flulike symptoms, including fever, headache, and muscle aches, followed within 2 to 7 days by a dry cough and pneumonia.

sporadic A pattern of disease occurrence in which a disease manifests only occasionally.

standard precautions The use of gloves, mask, goggles, gown, and shoe covers when handling body fluids or tissues of a patient who is not suspected of having a transmissible disease.

tolerance In immunology, the ability to distinguish between self and non-self cells.

transmission-based precautions Specific precautions used when a patient is suspected to have a particular illness.

universal precautions The isolation precautions taken when dealing with all patients regardless of their disease status.

vector An organism that carries a disease-causing microorganism from one organism to another.

ventilator-associated pneumonia (VAP) A type of hospital-acquired pneumonia that occurs in ventilated patients and that appears more than 48 hours after endotracheal intubation.

viremia The presence of viruses in the blood.

virion The complete viral particle, including DNA or RNA enclosed in a capsid, that is capable of infecting another cell.

virulence Physical or biochemical properties of a disease agent that determine its pathogenicity.

virulence factors Adaptations of microbes that enable them to penetrate the immune defenses.

West Nile virus (WNV) An arthropod-borne *Flavivirus* that is spread to birds and humans by mosquitoes; it may be characterized by sudden onset of fever with malaise, anorexia, nausea, vomiting, eye pain, headache, myalgia, rash, lymphadenopathy, fatigue, and arthralgias.

zoonosis A disease that occurs in animals and can also be transmitted to humans.

CHAPTER 21

Toxicologic Emergencies

Jason Chu, MD
Theodore C. Bania, MD, MS

OBJECTIVES

After completing this chapter, you will be able to:

1. Identify issues that may adversely affect the health and safety of critical care transport professionals during the treatment and transport of patients experiencing a toxicologic emergency (p 1131).
2. Describe assessment of and considerations common to all patients following a poisoning or overdose (p 1130).
3. Discuss the assessment findings associated with the various toxidromes and medication reaction syndromes encountered in the critical care environment (p 1138).
4. Discuss situations in which various means of decontamination are required or indicated following a toxic exposure or overdose (p 1141).
5. Identify those chemicals or medications that require enhanced elimination (removal of absorbed toxins) from the body (p 1145).
6. Identify the clinical presentation, mechanism of toxicity, and treatment of poisoning or overdose situations involving pharmaceutical and abuse agents (p 1146).
7. Identify the clinical presentation, mechanism of toxicity, and treatment of poisoning or overdose situations involving chemical agents (pp 1160–1161).
8. Recognize especially toxic substances that pose extreme risks to patients and providers (p 1170).
9. Discuss hazardous materials response and critical care transport considerations in such incidents (p 1171).
10. Discuss radiation emergencies and critical care transport considerations (p 1173).

Introduction

Critical care transport professionals (CCTPs) may be asked to transport patients experiencing a toxicologic emergency following a vast array of possible events. Poisons, chemicals, medications, and other toxic substances are found in dangerous quantities in homes, schools, agriculture, industry, and commercial establishments; on all modes of transportation; and naturally in the environment. As a result of accidents, carelessness, intentional misuse, abuse, or intentional acts of others, such as terrorism, people may be exposed to these toxins and experience potentially lethal consequences. CCTPs can dramatically improve patient outcomes through prompt recognition and effective treatment of such toxicologic emergencies.

The safety of the transport team and other health care or emergency responders is the highest priority when the CCTP encounters a poisoned or overdosed patient. Patients may present hazards to rescuers in a variety of ways. Bizarre, aggressive, or violent behavior may accompany or follow a medication overdose. Suicidal patients may jeopardize the safety of others during a suicide attempt. Patients exposed to hazardous chemicals may contaminate and injure unprotected rescuers if thorough decontamination is not performed before they initiate treatment.

Management of toxicologic emergencies includes many interventions common to other areas of critical care transport. For example, care for a patient who has been poisoned or one with an overdose is based on the ABCs—maintaining a patent airway, supporting respirations, and promoting effective circulation. Additional steps involve protecting the patient from additional injury through decontamination, prevention of absorption, antidote administration, enhanced elimination, and general patient safety and comfort measures. In many toxicologic emergencies, decontamination, enhanced elimination, and antidote administration will not become effective rapidly enough to correct immediately life-threatening problems with the ABCs, with a few notable exceptions (eg, naloxone given for opioid overdose and atropine given for anticholinesterase toxicity). CCTPs are strongly discouraged from delaying basic ABC interventions while locating, administering, or waiting for a possible antidote to work. Wasted time will prove fatal in many cases. Interventions to maintain and enhance the ABCs are discussed in greater depth in Chapter 6, *Respiratory Emergencies and Airway Management*.

Two types of decontamination are distinguished in this text, each with a unique purpose. **Primary decontamination** usually is done at the scene or outside a health care facility or transport vehicle; it is intended to protect rescuers and health care providers from exposure to a toxic substance during patient care or transport. **Secondary decontamination**, in contrast, requires health care providers to use personal protective equipment (PPE) but is directed at minimizing patient absorption or injury from a toxic substance. The risk to health care providers during secondary decontamination is typically much less than that posed before or during primary decontamination. Gastric decontamination or eye irrigation should be performed well after the ABCs are addressed. Decontamination of a hazardous chemical should occur before an unprotected health care provider makes any contact with it. Both primary and secondary decontamination are beneficial to patients, but each must be considered separately to avoid confusion. Enhanced elimination is the practice of augmenting the body’s removal of a toxic substance (or metabolite) once systemic absorption has occurred.

The term *antidote* also requires clarification. Certain substances have an identified antidote, which counteracts toxicity through a mechanism clearly related to the particular toxic substance (eg, acetylcysteine [Mucomyst, Acetadote] for acetaminophen overdose). Other toxic exposures cause signs and symptoms amenable to treatment with a variety of medications used to treat these symptoms in other situations (eg, benzodiazepines may be used to treat seizures whether they are caused by toxic chemicals or something else). The line between antidote and other pharmacologic interventions is not important to the outcome but is mentioned here to avoid confusion in terminology. For many toxic substances, there is a preferred medication to treat a particular sign or symptom, but the term *antidote* implies a complete reversal of toxicity, which does not usually occur.

General Toxicologic Emergency Management

Assessment

Assessment of a patient after poisoning or an overdose should ideally begin well in advance of the first face-to-face contact with the patient. In many situations, if rescuers or health care providers do not use the correct PPE before initial patient contact, it will be too late for this equipment to provide adequate protection **FIGURE 21-1**.

Fire & Rescue

FIGURE 21-1 Adequate use of PPE during contact with patients limits the risk to rescuers and health care providers. The four levels of protection are identified as levels A through D. **A.** Level A protection is fully encapsulating, and includes self-contained breathing apparatus (SCBA). **B.** Level B protection is worn with an SCBA but is not fully encapsulating. **C.** Level C protection is geared toward a known agent. **D.** Level D protection is sometimes worn in the cold zone, an area where no environmental hazards should be present.

Once the safety concerns for health care providers and emergency responders have been adequately addressed, the transport team should evaluate and manage any problems with the patient's ABCs. The overall patient assessment should focus on identifying immediate threats to life and health, yet be comprehensive enough to disclose the subtle cues that may assist in the diagnosis of a specific type of toxic exposure.

Safety

When the transport team receives the initial dispatch or patient report, they should consider the safety precautions and potential hazards suggested by that information. CCTPs may encounter hazardous situations during anticipated patient transports between health care facilities, while responding to an emergency in the community, or by happening upon a vehicular crash without any warning.

Cues to the presence of toxic substances may include the following:

- The presence of unusual odors, smoke, or vapors
- Signs, placards, or markings indicating chemicals or hazardous materials
- Vehicles known to carry chemicals (such as tank cars and fuel trucks)
- Industrial, manufacturing, agricultural, or laboratory facilities
- Bystanders or rescuers becoming unexpectedly ill or unconscious
- Multiple patients with similar unexpected signs and symptoms

The transport of a patient exposed to a toxic substance should not pose an increased risk to CCTPs if safety considerations are adequately addressed.

CCTPs risk illness or injury if they do not use PPE and adequate decontamination has not occurred before they treat patients exposed to toxic substances. Depending on the profile of the critical care transport agency, providers may or may not be actively involved in extrication and decontamination at hazardous material scenes. Nevertheless, all transport providers must assess the adequacy of PPE and decontamination before making patient contact or placing the patient in the transport vehicle. Contaminated patients may expose health care providers to potentially lethal substances or incapacitate a pilot or driver, leading to a possible crash. Decontamination is discussed in greater depth later in this chapter. Crew members should consult a Poison Control Center at the nationwide number, 1-800-222-1222; CHEMTREC at 1-800-262-8200; or a reliable reference source before approaching or transporting a patient exposed to suspected hazardous materials.

In addition to chemical hazards that pose a risk to health care providers and emergency responders, patients may exhibit violent, bizarre, or aggressive behavior. Hospital security staff, law enforcement personnel, or a sufficient number of trained health care providers may be necessary to restrain an aggressive or confused patient before any real assessment or treatment can begin. Intoxicated patients and patients with psychological or emotional disorders can pose a significant risk to health care providers and emergency responders. Potentially suicidal, combative, aggressive, violent, intoxicated, and confused patients should be restrained before transport. Physical restraint includes a spectrum of options, ranging from soft limb restraints, to four-point leather or nylon restraints with additional cross-straps, to handcuffs and shackles for transport of prisoners (prisoners are almost always handcuffed even when they are sedated, intubated, or paralyzed). CCTPs should follow their local and agency policies when applying or transporting patients with physical restraints. It is also imperative for CCTPs to monitor ventilation, make provisions to ensure crew safety, and have a means to release restraints if warranted by acute changes in patient condition.

In addition to physical restraints, CCTPs should consider medical therapy for patients who pose a physical risk to providers. Medical therapies may range from a mild oral sedative to an intravenous sedative, paralysis, and intubation for extremely high-risk patients. Local guidelines should be followed for the use of pharmacologic treatments. Air medical crews should consider alternative ground transport if patients cannot be adequately restrained. Ground transport crews should consider taking extra personnel or delaying transport if crew safety cannot be ensured. Note, however, that patients should not be intubated solely for the purpose of making it safe to transport them.

All patients should be evaluated for the presence of weapons before transport begins. CCTPs should also be aware of family members, visitors, and prospective passengers who might be carrying weapons or are exhibiting dangerous behavior. CCTPs should not approach an unsecured scene without law enforcement involvement when there is an increased likelihood of aggression or violence.

The following cues suggest there is an increased risk of aggression or violence:

- Reported suicide attempt or mental illness
- History of violent behavior

- Involvement of alcohol, illicit drugs, or medication or chemical abuse
- Altered or confused mental status
- Patients with escape risk (eg, prisoners and inpatient psychiatric patients)

Airway

Once safety concerns have been addressed, maintaining or establishing a patent airway is the top priority in the management of a patient with a toxic exposure. Transport team members must evaluate whether the patient currently has a patent airway and is at significant risk for developing airway compromise during the transport. Patients who are awake, alert, and speaking without difficulty demonstrate a patent airway. Unusual sounds from the airway, such as stridor, snoring respirations, and gurgling noises, indicate that the airway is at least partially compromised. In addition, visual signs such as secretions, blood, edema, and foreign substances in the airway indicate a potentially compromised airway. CCTPs should continually monitor all patients—but especially patients who have been exposed to caustic liquids (eg, acids or alkali) or gases (eg, chlorine gas or anhydrous ammonia). Caustic agents continue to react and may produce progressive airway occlusion over the course of several minutes.

A previously patent airway may become compromised during patient transport for a number of reasons. Any subsequent alteration in mental status or seizure activity may compromise the airway in a poisoned patient or a patient with an overdose. Evolving structural abnormalities from trauma or increasing edema may also jeopardize a previously patent airway. Obstructions may occur from emesis (especially unrecognized), secretions, a foreign body, or an airway that becomes displaced during the transport, leading to airway compromise.

Sometimes CCPTs may encounter patients who received activated charcoal, which presents an unusual risk of subsequent airway compromise. In supine or sedated patients, aspiration may easily occur. Aspiration of activated charcoal from an inadequately protected airway will increase morbidity and may be lethal. In patients with unprotected airways who have been given charcoal, some protection from aspiration can be afforded by maintaining a minimum 30° angle elevation of the head of the stretcher at all times. Aspiration is often a silent event, so if any doubt arises about the patient's ability to protect the airway during transport, the CCTP should secure the airway with an endotracheal (ET) tube.

Breathing

Breathing is second only to the airway in importance during patient assessment. Patients require effective oxygen delivery and ventilation to supply the body with oxygen and to remove carbon dioxide. Without effective oxygenation and ventilation, tissue hypoxia, acidosis, and cell death will occur.

The CCTP must evaluate whether a patient's oxygenation and ventilation are adequate to meet the body's metabolic needs. In addition, the CCTP must identify patients who are at risk for subsequent respiratory compromise so that appropriate interventions may begin. Despite breathing spontaneously, patients may not be oxygenating and ventilating adequately to meet their physiologic needs following a poisoning or overdose. Patients with apnea require total extrinsic ventilatory support. In either case, oxygenation and ventilation need to be supported externally with positive-pressure ventilation and/or supplemental oxygen. It is important to provide the correct oxygen concentration and ventilator settings for each patient and clinical situation. For example, patients with carbon monoxide poisoning should receive 100% oxygen despite normal oxygen saturation readings. Conventional pulse oximetry devices can only differentiate between oxyhemoglobin and deoxyhemoglobin; consequently, carbon monoxide that is bound to hemoglobin is misinterpreted as oxyhemoglobin by these devices.

A patient's intrinsic or ventilator-controlled rate and tidal volume must provide adequate gas exchange for the patient's clinical status. Physiologic stress, acidosis, hypermetabolic states (such as in pediatric patients), and many toxic substances require greater oxygenation and ventilation than would normally be required. In turn, the CCTP must consider these factors when evaluating a patient's respiratory status. Conventional ventilator settings are often inadequate for a patient's needs following a poisoning or an overdose. Indeed, catastrophic consequences may occur if a patient who is hyperventilating to compensate for severe metabolic acidosis is pharmacologically paralyzed and conventional ventilator settings are used. When such treatment is applied, respiratory compensation no longer protects the body from the devastating effects of the metabolic acidosis, leading to widespread organ, tissue, and cell dysfunction. Alterations in pH will also occur if a patient has underlying metabolic alkalosis and receives aggressive mechanical ventilation, further disrupting the essential pH balance. Any deviations from normal pH impair the performance of body systems.

Pulmonary edema, hypoxia, cardiovascular dysfunction, and hypermetabolic states all require special consideration when initiating and adjusting positive-pressure ventilation. Hypermetabolic states require greater ventilation for removal of carbon dioxide than would otherwise be required. Cardiovascular dysfunction, persistent hypoxia, pulmonary edema, and acute respiratory distress syndrome may benefit from precise adjustment of positive end-expiratory pressure. Chapter 6, *Respiratory Emergencies and Airway Management*, provides a more in-depth discussion of ventilator settings.

Clues in the patient's history of present illness and physical examination will alert the CCTP to the increased likelihood of impending respiratory compromise. Many toxic exposures will affect a patient's respiratory status either directly or indirectly. Direct toxins, including asphyxiants, organophosphates, and neuromuscular blockers, affect gas exchange, airway diameter, lung tissue, and ventilation. Indirect toxins, such as opioids, benzodiazepines, tricyclic antidepressants (TCAs), and ethanol, inhibit a patient's central respiratory drive. Hypoxia may occur when gases displace oxygen in the lungs, substances block cellular oxygenation, and agents cause cardiogenic or noncardiogenic pulmonary edema. In addition, respiratory compromise may develop as a result of associated trauma, burns, or aspiration. Cyanosis, fatigue, and dyspnea all indicate that a patient’s respiratory status may be compromised. Wheezing, pulmonary edema, and decreased, absent, or coarse breath sounds found during lung auscultation further indicate unstable respiratory status.

Oxygen saturation, blood gas analysis, and end-tidal carbon dioxide ($ETCO_2$) provide valuable information when the CCTP is assessing the adequacy of oxygenation and ventilation. Changes in breath sounds, patient appearance, and cardiovascular function (as shown by electrocardiogram [ECG] and assessment of perfusion) may indicate either improving or worsening respiratory functioning during transport. **Pulse CO-oximetry** is a technology that provides for noninvasive screening and monitoring for methemoglobinemia and carbon monoxide exposure **FIGURE 21-2**.

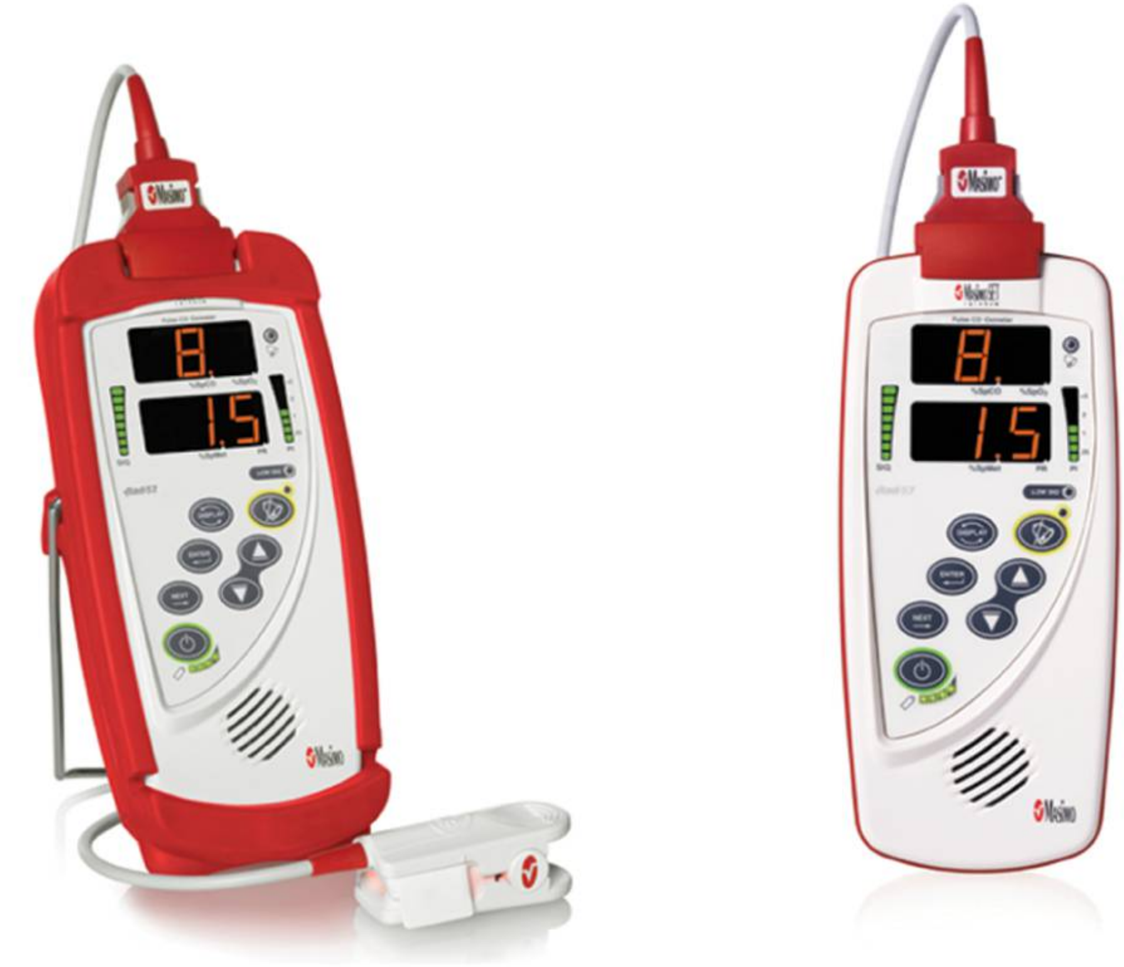

FIGURE 21-2 The Masimo Rad-57 Pulse CO-Oximeter allows clinicians to noninvasively measure oxygen saturation (SpO_2), carboxyhemoglobin (SpCO), and methemoglobin (SpMet) levels in the blood, as well as total hemoglobin (SpHb) and the pleth variability index (PVI; a measure of perfusion) for fluid responsiveness using a finger sensor.

Circulation

The evaluation of a patient’s circulation requires assessment of end-organ tissue perfusion and overall cardiovascular functioning. Previously healthy people may experience vast alterations in hemodynamic parameters without losing end-organ tissue perfusion.

Conversely, patients with longstanding cardiovascular disease may experience devastating consequences from modest hemodynamic alterations that are normally well tolerated in healthier people.

In patients with intact circulatory functioning, adequate end-organ tissue perfusion is demonstrated by normal mental status and adequate urine output for their ages or weights. Such patients will have strong distal pulses and “normal” heart rate, blood pressure (BP), and other hemodynamic values for their age and weight. Their skin will be warm and dry, with a capillary refill time of less than 2 seconds. The ECG will show a normal sinus rhythm (or the patient’s baseline rate and rhythm) without signs of conduction abnormalities, unusual ectopy, or ischemia. Any deviation from these findings suggests that the patient’s circulation may potentially be compromised.

Numerous mechanisms may impair a patient’s cardiovascular functioning after an exposure to a toxic substance. During the evolution of a toxic exposure, a patient’s circulatory status may decline because of any of the following factors:

- Direct exposure to cardiotoxic or vasoactive substances
- Fluid volume loss or redistribution
- Electrolyte disturbance
- Airway or respiratory compromise with secondary cardiac dysfunction
- Manifestations of preexisting cardiovascular disease
- Altered oxygen-carrying capacity

A history of exposure to agents with the potential to cause any of these events provides a clue that a patient’s circulatory status may become impaired before, during, or after transport.

Circulatory support for critically ill patients includes managing cardiac function, fluid balance, and vascular tone. Unfortunately, toxic exposures may adversely affect all of these components simultaneously. Sometimes impaired circulation is caused by an airway or breathing problem, resulting in hypoxia and/or ischemia. In such a case, the impaired airway or breathing condition may also be resolved by a cardiovascular intervention, such as for pulmonary edema.

Cardiac function is managed by administering medications that increase or decrease the heart rate or contractility. The therapy provided to an individual patient may be guided entirely by the patient's response or tailored specifically to the toxic substance involved. CCTPs should consult a reliable toxicology reference, a physician, or a Poison Control Center for specific guidance.

Fluid balance is closely related to vascular tone, kidney function, and electrolyte concentrations. Toxic exposures may cause alterations in any of these factors, requiring corrective action. CCTPs should anticipate the need for fluid volume replacement in hypovolemic patients or for diuresis of fluid-overloaded patients when managing circulatory function. In addition, they may need to remove excess electrolytes, replace them, or change their distribution.

Vascular tone is often managed with intravenous (IV) vasodilator or vasoconstrictor medications. Beta blockers, calcium channel blockers, catecholamines, and nitrates are used along with agents required for specific toxic substances to optimize vascular tone. For guidance in choosing the appropriate medications, CCTPs should consult a toxicology reference, a physician, or a Poison Control Center.

Additional Assessment

Patient assessment is not limited to just safety and the ABCs. Ideally, every patient transported will be assessed with a thorough history and physical examination. The depth and detail of the additional assessment should be balanced against the needs for prompt transportation and immediate clinical interventions.

The history of present illness should include the following details:

- The medication(s) or substance(s) involved (including multiple substances, particularly with intentional poisonings)
- Time, quantity, and duration of exposure

- Route(s) of exposure
- The patient's initial and subsequent clinical status
- Initial decontamination, stabilization, and treatment performed before arrival of the transport team
- Other contributory information, such as accidental versus intentional event, multiple patients, and the presence of environmental hazards

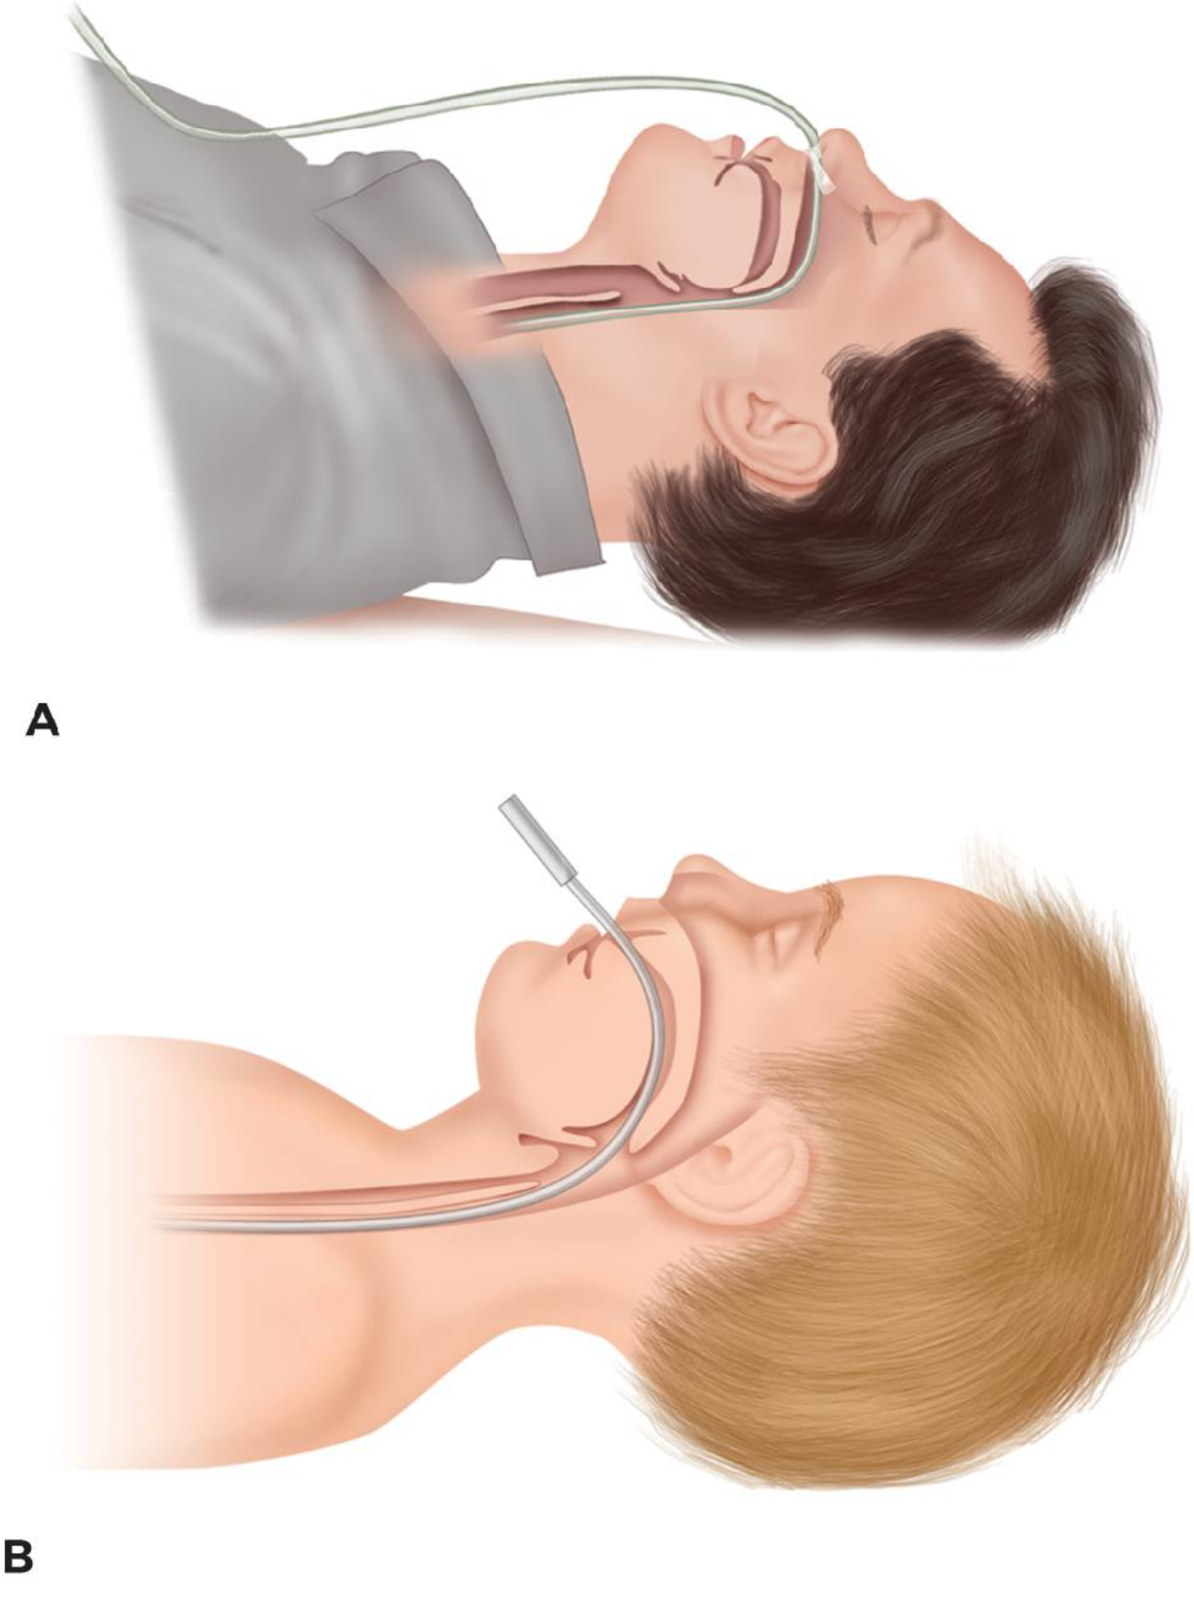
Interviews of patients, family, and bystanders may provide valuable clues to the nature and severity of a toxic exposure. Through interviews, the CCTP may become aware of **prodromal** symptoms not otherwise discoverable during the physical examination (eg, nausea, headache, and dizziness). An interview may be abbreviated or completed during the transport if interventions or transport cannot be delayed.

Knowing a patient's medical and social history, prescribed medications, and allergies will assist health care providers when they are treating and transporting a patient. Preexisting medical conditions may have a profound effect on the severity of a toxic exposure or overdose. Long-term exposures to various substances often present much differently from a single, brief, acute exposure to the same substance. Other factors, such as a history of a psychiatric disorder or substance abuse, may affect the present treatment plan and the discharge and follow-up options.

The physical examination performed by the CCTP must be appropriate for the clinical situation. Transport teams must balance the usefulness of a complete head-to-toe physical examination with concerns for patient thermoregulation (hyperthermia or hypothermia), privacy, patient access in confined transport vehicles, and the patient's clinical needs. Do not delay transport of a critically ill patient by performing a time-consuming comprehensive history and head-to-toe examination; conversely, do not initiate rapid transport before adequately assessing the patient.

Some patients may require only minimal intervention following a suspected poisoning or drug overdose. A toddler who possibly ingested a limited amount of a minimally toxic substance is often managed with only observation for a prescribed period of time. Other patients may become critically ill immediately following a toxic exposure, requiring immediate invasive therapy and exhaustive critical care resources. CCTPs must evaluate the details of each situation and weigh the indications, risks, and benefits of each intervention considered for the specific patient. They must also provide continuous assessment and monitoring of any patient being transported. Such monitoring must be within the skills of the transport team and adequate given the patient's clinical status. It is far better to perform excess monitoring (eg, ECG monitoring after exposure to a minimally toxic substance) than inadequate monitoring (eg, no capnography on an intubated patient).

CCTPs should establish vascular access sufficient for administering emergency medications and fluids in any patient who was exposed to a potentially harmful substance. Intraosseous access can be used as an alternative route of administration for fluids and most antidotes. Intubated patients require a nasogastric or orogastric tube for stomach decompression and protection from aspiration. Note that gastric tubes should not be used in patients who have ingested caustic substances, as they might cause additional injury. Caution is also warranted if an ingested toxin is present in the stomach and decompression will expose the CCTP to this substance **FIGURE 21-3**. Patients who are unresponsive and those who require urine output monitoring should have an indwelling urinary catheter inserted and attached to a urine collection device.



A
B

FIGURE 21-3 A nasogastric (**A**) or orogastric (**B**) tube is required for stomach decompression and protection from aspiration in intubated patients.

© Jones & Bartlett Learning.

All patients who require paralytic drugs must receive adequate sedation and analgesia. If the patient is at risk of seizure activity, as many poisoning and overdose patients are, then seizure prophylaxis must be administered. Vital signs, especially following a poisoning or overdose, are *not* a reliable method of measuring patient sedation or comfort. CCTPs frequently encounter unwarranted administration of antihypertensive medications to patients who are medically paralyzed but have not received adequate analgesia or sedation. Discomfort is a common cause of unexplained hypertension and tachycardia in an intubated and paralyzed patient. Analgesia and sedation should be administered frequently enough to avoid subtherapeutic levels. In addition, patients with increased drug tolerance or hypermetabolic states require significantly more sedation and analgesia while paralyzed. Modern noninvasive commercial devices that permit monitoring of sedation in intubated and medically paralyzed patients, such as the bispectral index monitor, are available.

All patients should receive treatment that provides for their maximum comfort, privacy, and dignity, within the context of the clinical situation. Patients should also be protected from unintentional temperature alterations. Environmental exposure (eg, to heat, cold, moisture, or noise) during transport, while loading or unloading patients, and in health care facilities can adversely impact patient care. Moreover, patients experience the same stressors of flight as do air medical crew members, but are frequently more susceptible to their negative effects and lack sufficient reserves to avoid their detrimental consequences. Patients in ground transport units traveling through significant altitude changes will experience physiologic stressors similar to those encountered in flight.

Nonintubated patients may require **anxiolysis** and analgesia following many toxicologic exposures. Psychiatric and other at-risk patients may require sedative medications to facilitate care and promote comfort. Family members and friends should be assessed for dysfunctional coping during any crisis situation.

Vital Signs

A vast array of toxic substances will cause altered vital signs in an exposed patient. Hemodynamic and respiratory alterations occur from direct action of these substances on various organs and tissues or through effects on the central nervous system (CNS), which regulates the cardiovascular and respiratory systems. The examples that follow identify only a few of the many medications and substances that can lead to changes in patients' vital signs.

Tachycardia may occur following a toxic exposure to several different classes of medications and chemicals. Sympathomimetics, such as amphetamines, caffeine, and cocaine, produce an increase in sympathetic tone and atrioventricular (AV) node conduction, increasing the heart rate. Medications with anticholinergic effects (eg, atropine, TCAs, and antihistamines) antagonize acetylcholine and enhance sinus node discharge, causing sinus tachycardia. In addition, any substance that causes cellular hypoxia (eg, carbon monoxide and cyanide) will produce responsive tachycardia in the patient. Various medications and chemicals may also induce ventricular tachyarrhythmias or myocardial ischemia with related tachycardia. The list of chemicals and medications with the potential for causing tachycardia is extensive.

Bradycardia may occur early following exposure to a toxic substance or immediately preceding asystole as the exposure evolves into a fatal event. CNS depression causing bradycardia occurs with toxicity from ethanol, benzodiazepines (eg, lorazepam, diazepam, and midazolam), clonidine, gamma-hydroxybutyric acid, and opioids, to name a few agents. Cardiac glycosides (digoxin) delay conduction through the AV node, leading to bradycardia and heart block. Organophosphates and carbamates cause bradycardia by increasing vagal tone. Bradycardia may also be triggered by direct action on myocardial cell membranes by calcium channel blockers, beta-adrenergic blockers, tricyclic antidepressants, household poisons, and other substances.

Hypertension accompanies tachycardia and bradycardia following exposure to some medications and chemicals. The sympathomimetic agents and anticholinergic agents described earlier, for example, result in hypertension with tachycardia. For instance, norepinephrine and phenylephrine can cause hypertension with bradycardia or an AV block.

Hypotension may also be accompanied by tachycardia or bradycardia. Hypotension with tachycardia may result from fluid loss, third spacing, or blood vessel dilation. Cell membrane depressant agents and agents that depress the CNS can cause hypotension and bradycardia. These medications include opioids, sedative-hypnotic agents, beta blockers, calcium channel blockers, and various others.

Many chemicals and medications can affect temperature regulation. Hyperthermia may occur from increased muscle activity or seizures, an increased metabolic rate, impaired heat dissipation, and disrupted thermoregulation. Drug withdrawal and reactions to medications at therapeutic doses may also precipitate hyperthermia in specific high-risk populations. Examples of medications that may cause *hyperthermia* include cocaine, salicylates, and phenothiazines. Examples of medications that may cause *hypothermia* include beta blockers, benzodiazepines, ethanol, and hypoglycemic agents. In addition to alterations in metabolism, vasodilation, and impaired shivering response, a patient exposed to CNS depressants may lose consciousness in a cold environment, leading to exogenous hypothermia.

Laboratory Assessment

Laboratory analysis can assist the CCTP during diagnosis and treatment of a patient with an actual or potential toxic exposure. Analysis of blood and urine samples is routinely available at sending hospitals and clinics. Advances in **point-of-care testing** technology also allow CCTPs to measure blood chemistry values, arterial and venous blood gases, and other assorted values during the transport and receive almost immediate results. Be aware, however, that not all chemicals are included in standard toxicology screens.

Certain toxic exposures require a specific approach to laboratory evaluation once the diagnosis is made. In these circumstances, the toxic substance has a predictable effect on various laboratory values. Such tests are used to guide treatment or monitor patient status. CCTPs do not often have the luxury of a definitive diagnosis before transport and must use available laboratory testing as a screening or an assessment tool.

Laboratory testing may also provide evidence that patients are not able to provide owing to their current condition. Patients who are exposed to a chemical or medication and who arrive unresponsive or with an altered mental status cannot provide a reliable history and require a thorough screening for life-threatening conditions. In addition, suicidal and psychiatric patients may intentionally provide misleading or incomplete information to health care providers.

The laboratory assessment should include the following elements:

- Acetaminophen level: 4 hours after exposure when the time of ingestion is known, or immediately when the time of ingestion is not known
- Salicylate level: drawn immediately for a baseline and then repeated at least 1 to 2 hours after exposure; repeated testing is needed for a positive value or a possibility of delayed absorption
- Serum electrolytes, including glucose and potassium (particularly if paralysis with succinylcholine [Anectine] is a possibility)
- Evaluation of acid–base status through arterial or venous blood gas or serum bicarbonate testing
- Ethanol level
- Serum levels of any chemicals and medications known to be available to the patient for which tests can be done (eg, digoxin, lithium, phenytoin [Dilantin], and valproic acid [Depakote])
- Anion gap: serum sodium level minus the sum of chloride and bicarbonate; normal level, 8 to 16 mEq/L
- Osmolar gap if toxic alcohol poisoning is suspected
- Urine drug screen

The tests listed here are performed for screening purposes. If they yield any abnormal or positive results, further investigation is essential. Known exposure to a particular medication or chemical or profound clinical instability may require a more comprehensive laboratory assessment.

Toxic Syndromes and Medication Reaction Syndromes

Exposure to certain classes of chemicals and medications will produce a readily identifiable pattern of clinical signs and symptoms, called a **toxidrome**. These patterns aid in diagnosis when the exact nature of the exposure is unclear and permit health care providers to initiate the correct life-saving interventions. CCTPs should be careful not to overlook other possible causes when making treatment decisions based solely on identification of a toxidrome.

In some cases, patients may experience life-threatening reactions to medications taken at therapeutic doses. Prompt recognition of these rare events is essential and will happen only if health care providers recognize the unusual clues or at-risk patients. Misdiagnosis of these events will adversely affect patient care, with possibly lethal consequences.

TABLE 21-1 lists some of the most common toxidromes and medication reaction syndromes.

Toxic Syndromes (Toxidromes)

Anticholinergic syndrome occurs following excessive exposure to medications such as antihistamines, atropine, benztropine (Cogentin), TCAs (amitriptyline [Elavil]), and some other substances, such as jimson weed. Poisoning results in muscarinic receptor blockade within the CNS and various other organs. In anticholinergic syndrome, patients demonstrate tachycardia, hyperthermia, dilated (mydriatic) pupils, warm (or hot) dry skin, ileus, delirium, seizures, hallucinations, and urinary retention. Seizure activity is treated with benzodiazepines (eg, lorazepam, diazepam, and midazolam) and phenobarbital if the patient does not respond to benzodiazepines. Severe toxicity may be treated with physostigmine (Antilirium, Isopto Eserine), though it should be administered only after consultation with a toxicologist.

Cholinergic syndrome (cholinesterase inhibitor toxicity) typically occurs following exposure to organophosphate and carbamate insecticides or to certain chemical nerve agents. Cholinesterase inhibitors may affect nicotinic receptors, muscarinic receptors, or both, and alter the function of the neurotransmitter acetylcholine. Patients may have two distinct patterns of toxicity, depending on which receptors are involved. Nicotinic receptor toxicity produces tachycardia, hypertension, fasciculations, weakness, hyperglycemia, and dilated pupils. Muscarinic receptor toxicity produces the classic **SLUDGEM** syndrome (Salivation, Lacrimation, Urination, Diarrhea, Gastroenteritis, Emesis, and Miosis) plus bronchorrhea, bronchospasm, sweating, and bradycardia. The mnemonic **DUMBELS** (Diaphoresis/diarrhea, Urination, Miosis, Bradycardia/bronchospasm/bronchorrhea, Emesis, Lacrimation, and Salivation) can also be used to remember these symptoms. Nicotinic and muscarinic toxicity leads to altered mental status, coma, and seizure activity in patients with severe exposures to cholinesterase inhibitors. It is essential that health care providers and rescuers use adequate PPE during evaluation and treatment of these exposed patients. Atropine, in doses much higher than are used in typical Advanced Cardiac Life Support protocols, and pralidoxime are the antidotes for cholinesterase inhibitor toxicity. Seizure activity is treated with benzodiazepines. In addition to antidotal therapy, airway and ventilation management should be a high priority due to the bronchorrhea and bronchospasm associated with these exposures.

Both prehospital and emergency department health care providers frequently encounter patients with **opioid syndrome**. This toxicity commonly develops following illicit use or abuse of opioids in the community, or as an adverse consequence of a therapeutic error or accidental ingestion of opioids (eg, morphine, heroin, and fentanyl [Duragesic]). Signs include lethargy, sedation, hypoventilation, apnea, pinpoint pupils, and noncardiogenic pulmonary edema. Treatment focuses on airway and ventilation support and the prompt administration of an opioid antagonist such as naloxone (Narcan).

CCTPs should be aware that administration of an opioid antagonist may precipitate severe, violent withdrawal symptoms. In addition, many opioids may exert effects that last much longer than the duration of opioid antagonists, which means that life-threatening symptoms may return after the medication wears off. It is often necessary to use repeated doses of opioid antagonists in severe overdose situations.

Sedative-hypnotic syndrome occurs following exposure to any medication or chemical that can cause CNS sedation, lethargy, or coma. The most common cause is ethanol, but other potential causes include benzodiazepines, gamma-hydroxybutyric acid, sleep aids (diphenhydramine [Benadryl], zolpidem [Ambien]), barbiturates, selective serotonin reuptake inhibitors (SSRIs), and trazodone

(Desyrel). Signs can include lethargy, sedation, hypoventilation, apnea, bradycardia, and hypotension. Opioid syndrome, in fact, can be viewed as a subset of sedative-hypnotic syndrome. Treatment of sedative-hypnotic syndrome is, therefore, similar to treatment for opioid syndrome, focusing on airway, ventilation, and circulatory support. Unlike for opioid syndrome, there is not a good antidote for most of the causes of sedative-hypnotic syndrome.

Sympathomimetic syndrome involves overstimulation of the adrenergic nervous system, which results in tachycardia, hypertension, agitation, seizures, hyperthermia, dilated pupils, and diaphoresis. An isolated alpha-adrenergic or beta-adrenergic syndrome may cause bradycardia or hypotension, respectively, but the classic (mixed) syndrome involves the listed symptoms. Amphetamines, caffeine, cocaine, MDMA, synthetic cathinones, and synthetic cannabinoids may all cause sympathomimetic syndrome. Treatment is primarily supportive, involving benzodiazepines for sedation and aggressive cooling measures. Hypertension should be treated with direct-acting vasodilators. Beta blocker drugs should be avoided or used with extreme caution in patients with sympathomimetic syndrome because of the risk of unopposed alpha-adrenergic stimulation worsening the hypertension.

Signs and Symptoms

Anticholinergic Syndrome

- Tachycardia
- Hyperthermia
- Dilated (mydriatic) pupils
- Warm (or hot) dry skin
- Ileus
- Delirium
- Seizures
- Hallucinations
- Urinary retention

Nicotinic Receptor Toxicity

- Tachycardia
- Hypertension
- Fasciculations
- Weakness
- Hyperglycemia
- Dilated pupils

Muscarinic Toxicity

- SLUDGEM symptoms: Salivation, Lacrimation, Urination, Diarrhea, Gastroenteritis, Emesis, and Miosis
- DUMBELS symptoms: Diaphoresis/diarrhea, Urination, Miosis, Bradycardia/bronchospasm/bronchorrhea, Emesis, Lacrimation, and Salivation

Opioid Toxicity

- Lethargy and sedation
- Hypoventilation or apnea
- Pinpoint pupils
- Noncardiogenic pulmonary edema

Sedative-Hypnotic Toxicity

- Lethargy and sedation
- Hypoventilation or apnea

Sympathomimetic Toxicity

- Tachycardia
- Hypertension
- Agitation
- Seizures
- Hyperthermia
- Dilated pupils
- Diaphoresis

Medication Reaction Syndromes

Malignant hyperthermia is a condition that occurs following administration of succinylcholine or certain inhaled anesthetic agents to genetically susceptible patients. CCTPs may encounter this condition following a rapid sequence intubation (RSI) procedure in the prehospital setting or when responding to a health care facility to perform a patient transport. Affected patients exhibit muscle spasms, profound muscle rigidity, acidosis (metabolic or respiratory), hypercarbia, hyperthermia, tachycardia, tachypnea, myoglobinuria, rhabdomyolysis, and hyperkalemia, beginning up to 12 hours after exposure. Treatment involves aggressive cooling, correction of acidosis, and administration of dantrolene sodium, 2.5 mg/kg initially. Larger patients may require massive quantities of dantrolene for severe reactions; some reports have described the need for more than 36 vials, each containing 20 mg of dantrolene, with 3 g of mannitol. The Malignant Hyperthermia Association of the United States recommends that facilities stock 36 vials of dantrolene to provide initial treatment for a patient weighing 100 to 110 kg, who may require 8–10 mg/kg for stabilization.

Neuroleptic malignant syndrome (NMS) is a potentially fatal reaction to antipsychotic and neuroleptic medications (eg, haloperidol [Haldol], prochlorperazine [Compazine], promethazine [Phenergan], and risperidone [Risperdal]) as a result of excessive blockade of central dopamine receptors or abrupt withdrawal of dopamine agonists (eg, carbidopa/levodopa [Sinemet]). It is not dose dependent and has a 5% to 11% mortality rate overall. Affected patients often demonstrate hyperthermia, profound muscle rigidity, autonomic dysfunction, metabolic acidosis, and confusion. Severe manifestations include renal failure, respiratory failure, arrhythmias, and cardiovascular collapse. Treatment involves good supportive care, aggressive cooling, and muscle relaxation. Prompt, effective muscle relaxation with benzodiazepines, dantrolene, and nondepolarizing neuromuscular blocking agents will prevent many catastrophic consequences of NMS. Dopamine agonists (bromocriptine [Parlodel], ropinirole [Requip], amantadine [Symmetrel], levodopa) can be given as well.

Serotonin syndrome is an unusual response to serotonin-altering medications that produce hyperserotoninergic symptoms. SSRIs (eg, fluoxetine [Prozac], sertraline [Zoloft], and paroxetine hydrochloride [Paxil]), meperidine (Demerol), and monoamine oxidase inhibitors (eg, phenelzine sulfate [Nardil] and tranylcypromine [Parnate]) are the usual culprits. Amphetamines, TCAs, serotonin and norepinephrine reuptake inhibitors (SNRIs), and lithium are implicated less frequently.

Serotonin syndrome may occur following an SSRI (or similar) overdose or when the medications mentioned earlier are inadvertently combined. Affected patients demonstrate irritability, muscle rigidity, increased lower extremity rigidity compared to upper extremity, clonus, myoclonus, hyperthermia, diaphoresis, headaches, seizures, coma, tachycardia, and hallucinations. Treatment includes aggressive cooling, IV hydration, and seizure control. Muscle relaxation is achieved by providing sedation with benzodiazepines and nondepolarizing neuromuscular blocking agents. **Rhabdomyolysis** is treated with aggressive IV fluid administration. Serotonin antagonist medications (cyproheptadine [Peritol]) and atypical antipsychotic medications with serotonin antagonist activity (olanzapine [Zyprexa], chlorpromazine [Largactil]) have been used to counteract this syndrome but are not currently recommended for widespread use.

Signs and Symptoms

Malignant Hyperthermia

- Muscle spasms
- Profound muscle rigidity
- Acidosis (metabolic or respiratory)
- Hypercarbia
- Hyperthermia
- Tachycardia
- Tachypnea
- Myoglobinuria
- Rhabdomyolysis
- Hyperkalemia

Neuroleptic Malignant Syndrome

- Hyperthermia
- Profound muscle rigidity
- Metabolic acidosis
- Autonomic dysfunction
- Confusion

Serotonin Syndrome

- Irritability
- Muscle rigidity
- Hyperthermia
- Diaphoresis
- Headaches
- Seizures
- Coma
- Tachycardia
- Hallucinations

Decontamination

Patient decontamination following exposure to a toxic substance is directed at minimizing the quantity of that substance absorbed by the patient and the extent of any local damage. Decontamination may be as simple as providing the patient with fresh air for several minutes or as complicated as whole-bowel irrigation, which takes many hours to perform. Prompt, effective decontamination has the potential to prevent the fatal consequences of an otherwise lethal overdose. As the following topics relate to the CCTP, decontamination will be completed on scene prior to transport.

Skin Decontamination

Caustic agents and acetylcholinesterase inhibitors (such as pesticides and chemical weapons) can cause systemic toxic effects from dermal absorption. Numerous other chemicals cause severe local reactions or burns when placed in contact with skin. Given these risks, it is essential that health care providers use the correct PPE during skin decontamination. Skin decontamination, like all other methods of decontamination, is most effective if initiated immediately following exposure and may have no benefit if significantly delayed. Certain agents, such as lime (calcium oxide) and elemental metals, react violently with water and require a specialized approach to skin and eye decontamination.

To perform skin decontamination, remove any potentially contaminated clothing. Gently brush dry powders away, and then flush the affected area with copious amounts of water or saline **FIGURE 21-4**. During irrigation, pay particular attention to the patient's ears and groin, the area between the fingers and toes, and any skin folds. Hydrocarbon-based products often require a mild soap or shampoo for more effective removal.

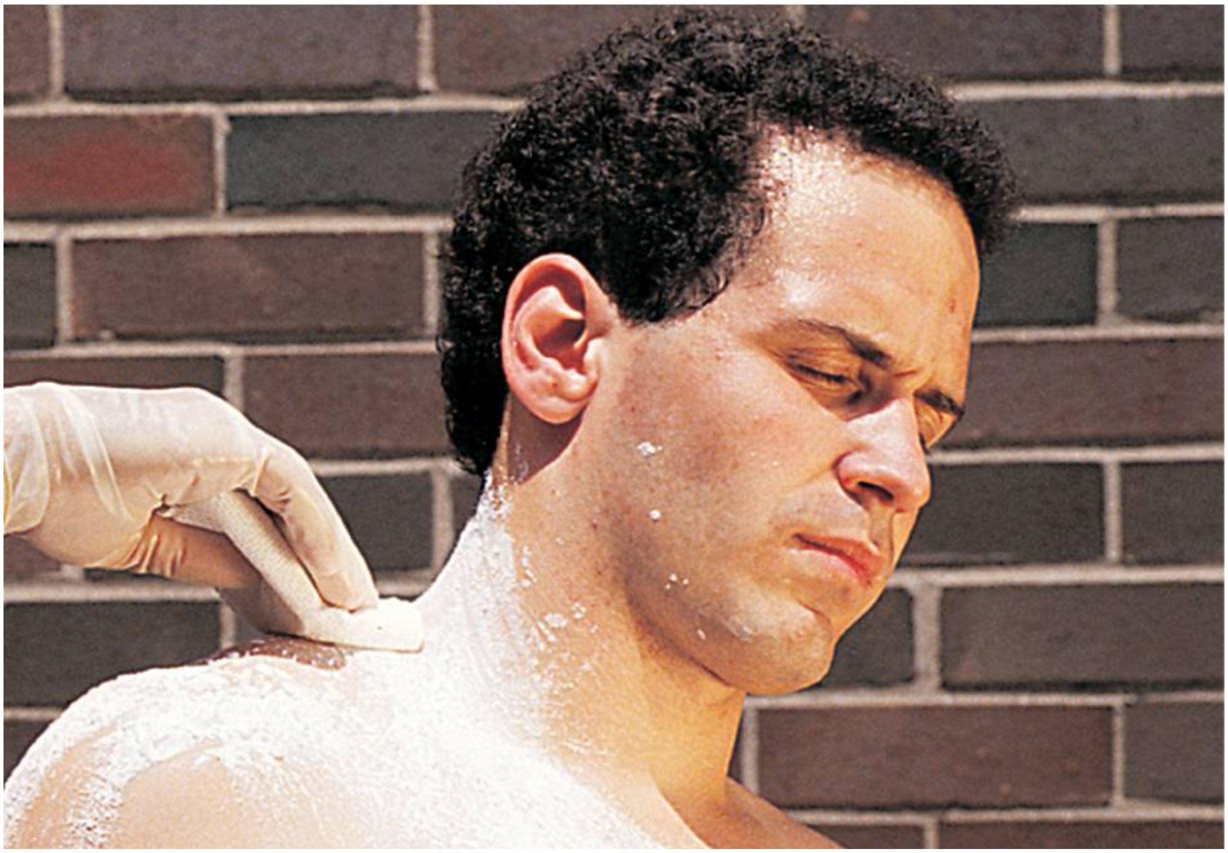

FIGURE 21-4 To decontaminate skin, gently brush away any dry powders before flushing the area with water or saline. Always ensure patients are protected against hypothermia after decontamination, because patients get cold quickly.

© American Academy of Orthopaedic Surgeons.

No attempt should be made to neutralize chemicals on the skin. Such a reaction often generates heat and causes additional injury.

Other chemicals recommended for topical treatment beyond irrigation include calcium for hydrofluoric acid exposure, calcium for oxalic acid exposure, and low-molecular-weight polyethylene glycol (PEG 400) or isopropyl alcohol for phenol exposure. Treatment with 1% copper sulfate solution for white phosphorus exposure is no longer recommended because of the risk of hemolysis and increased mortality from the copper. Consult a reliable reference before administering any topical treatment for chemical exposure.

Ocular Decontamination

Many agents that cause toxicity to skin will also damage the eyes. In particular, the cornea is extremely sensitive to hydrocarbons and corrosive agents.

Each affected eye should be flushed with copious amounts of water, saline, or other approved solution. Local ocular anesthetic drops, along with a commercially available irrigation adjunct (Morgan Lens), may be used as well **FIGURE 21-5**. Before beginning irrigation, remove the patient's contact lenses, if they are still in place **FIGURE 21-6**.

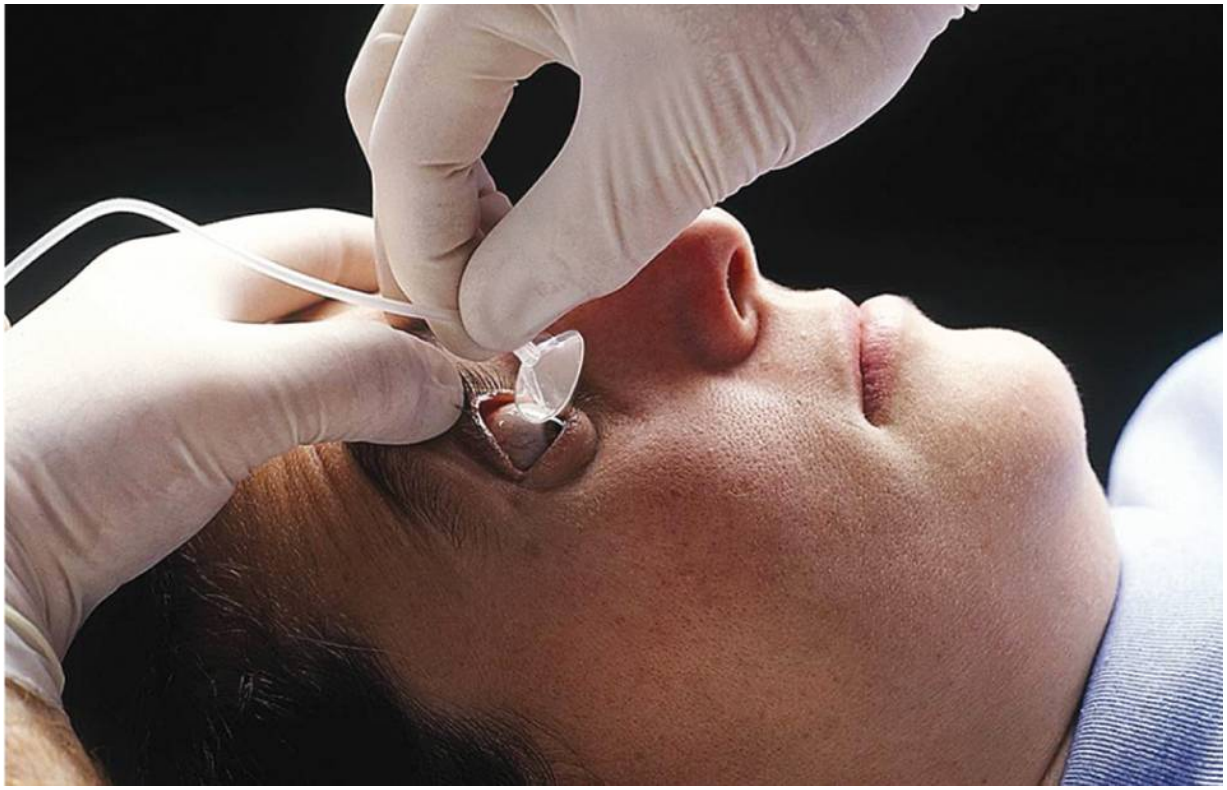

FIGURE 21-5 An irrigation adjunct, like the Morgan Lens, can help flush toxins away from the eye.

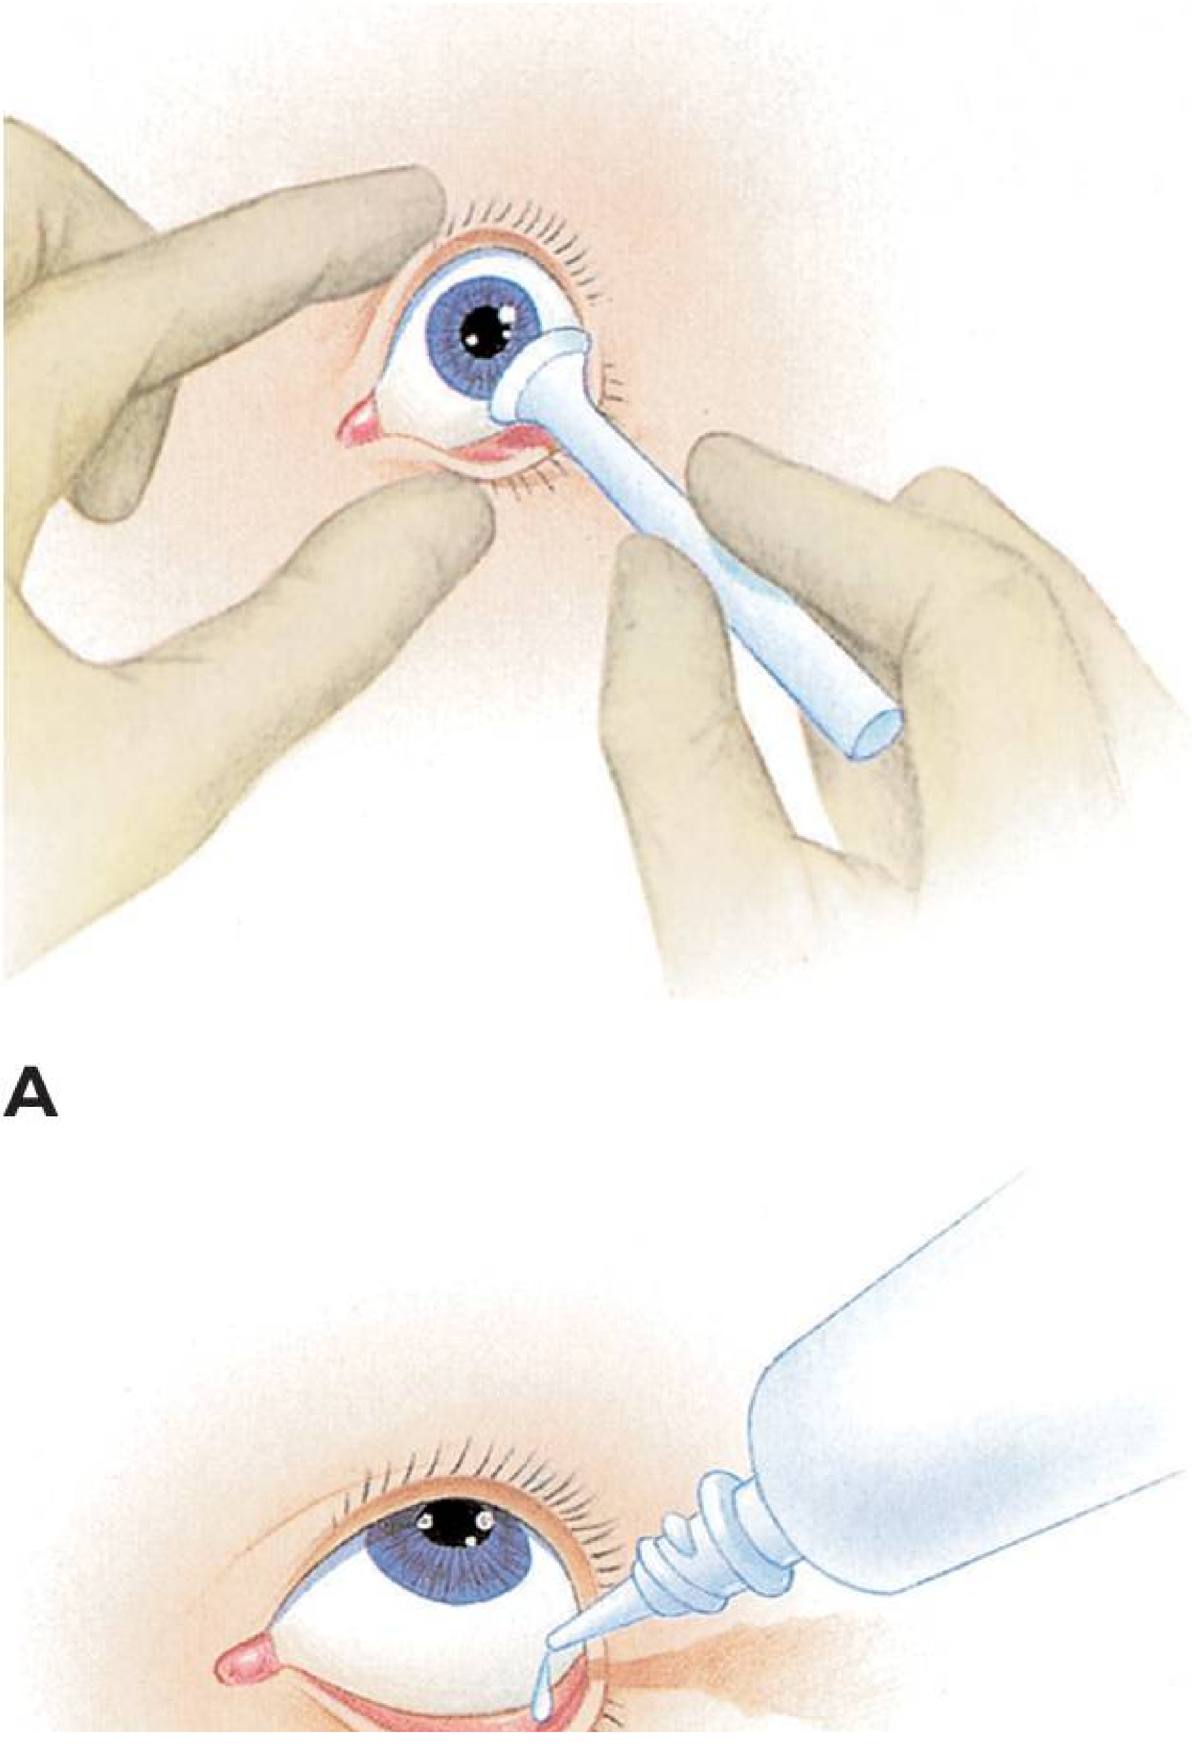
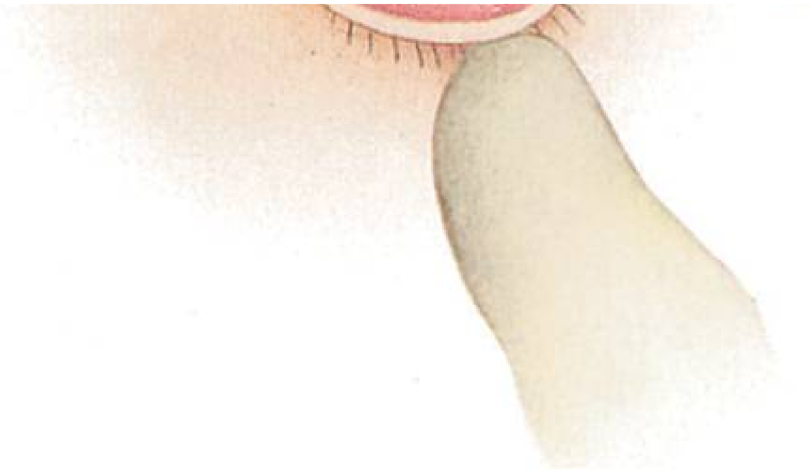
The Morgan Lens courtesy of MorTan, Inc.



A



B

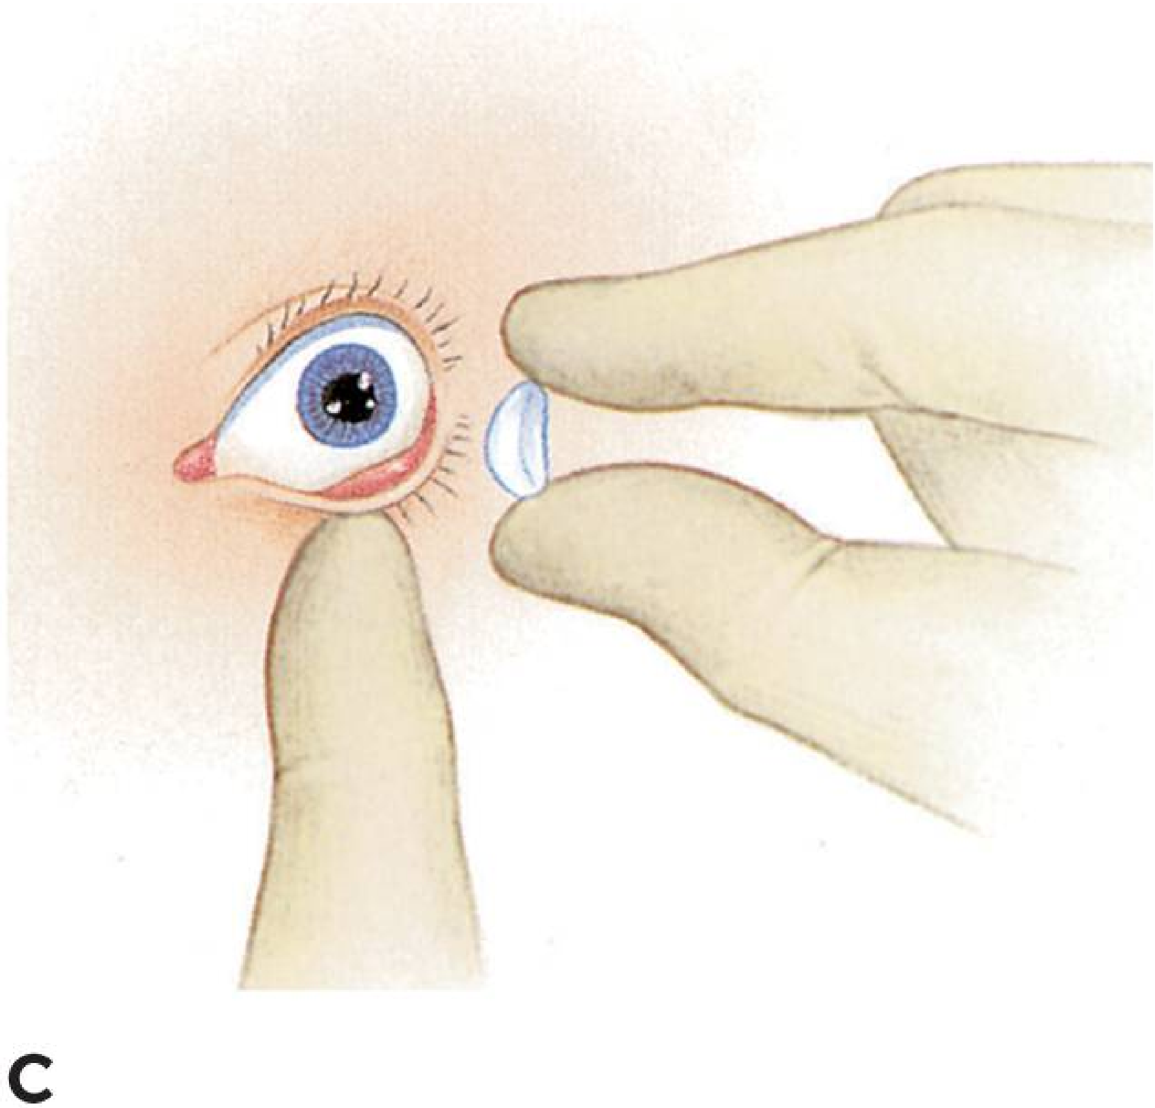


FIGURE 21-6 Remove contact lenses, if still in place, before beginning irrigation. **A.** To remove hard contact lenses, use a specialized suction cup moistened with sterile saline solution. **B.** To remove soft contact lenses, instill 1 or 2 drops of saline or irrigating solution. **C.** Pinch off the lens with your gloved thumb and index finger.

© Jones & Bartlett Learning.

Following exposure to an acid or base, each eye needs to be irrigated with at least 1 L of water until the ocular pH is normal. (Ocular pH is tested by touching the pH paper to the moist surface of the conjunctival cul-de-sac of the affected eye. The pH paper is then compared with the shades on the package.) No attempt should be made to neutralize chemicals in the eye. Such a neutralization reaction often produces heat, which then causes devastating injury. Once irrigation is complete, consult a Poison Control Center about definitive treatment or arrange for a thorough ophthalmology exam for any significant exposures.

Gastric Decontamination

Patients who have ingested toxic chemicals or dangerous amounts of otherwise therapeutic medications may benefit from gastrointestinal (GI) decontamination. GI decontamination is accomplished through gastric lavage and emptying, activated charcoal administration, and whole-bowel irrigation. In each case, the goal is to prevent systemic absorption of a toxic chemical or medication.

Orogastric Lavage

Pills, pill fragments, and liquid toxins can be removed from the stomach by gastric lavage. While once widely accepted, use of this procedure is now limited to a very small number of clinical situations. It is not performed in the transport setting. Patients who go to a health care facility within 1 hour of taking a life-threatening ingestion are candidates for gastric lavage. Indications include the following:

- Highly toxic ingestion, likely to remain unabsorbed in the stomach
- Substances poorly adsorbed by activated charcoal
- No effective antidote or treatment therapy currently available

Despite its potential for preventing harmful stomach contents from being absorbed, gastric lavage has several disadvantages. Notably, it is a time-consuming, invasive procedure that will delay administration of activated charcoal or oral antidote medications. The amount of actual pills (or fragments) that is removed is limited. Moreover, this procedure requires cooperation from awake, alert patients. Resistance is common, and use of sedative medications—given to counteract resistance—places patients at increased risk of aspiration. In addition, gastric lavage may propel toxic substances farther into the digestive tract and limit the effectiveness of other treatments.

The role of gastric lavage following a caustic ingestion is controversial. Contraindications include the following:

- Minimally toxic ingestion
- Significant time since ingestion and absorption has likely occurred
- Availability of a highly effective antidote
- Inability of the patient to protect the airway during the procedure (ET intubation may be required before gastric lavage)

In terms of complications, aspiration is the main risk during gastric lavage. Injury to the airway, stomach, and esophagus is also possible.

Highly toxic liquids can be evacuated from the stomach using a common orogastric or nasogastric tube much more quickly than they are removed by the conventional gastric lavage procedure.

Emesis induced by syrup of ipecac is no longer a routine treatment for toxic ingestions and is very rarely administered. Ipecac has many contraindications and side effects, almost completely eliminating its usefulness in toxic ingestions. Any patient who is sedated, is obtunded, or has a history of seizure activity is not a candidate for ipecac. Ingestion of any medication with the potential to induce CNS depression or seizures, any hydrocarbon, or any corrosive agent is an absolute contraindication to ipecac. Aspiration is a potentially lethal consequence of inappropriate administration of ipecac. Side effects of ipecac include sedation, vomiting-related trauma (including Mallory-Weiss tear), and delay in the administration of activated charcoal or oral antidote.

Activated Charcoal

Activated charcoal can often be administered to prevent absorption of medications and chemicals in the digestive tract. **Activated charcoal** is a carbon-based liquid with an incredible absorptive ability

FIGURE 21-7. It is typically administered orally or via a nasogastric or orogastric tube to decrease the available quantity of a toxic substance. This therapy also has the novel ability to remove certain toxic substances from circulating blood by "gut dialysis." Orally administered activated charcoal can reduce the available quantity of a purely IV overdose of certain medications (eg, theophylline and phenytoin) or decrease serum drug levels of some medications (eg, carbamazepine, salicylates, digoxin) long after systemic absorption has occurred. This ability is limited to selected chemicals, however.

FIGURE 21-7 Activated charcoal.

© American Academy of Orthopaedic Surgeons.

Activated charcoal is administered as a single dose for routine ingestions and in repeated doses for certain severe exposures. Adults usually receive 1 g/kg, and children receive 0.5 to 1 g/kg. This treatment is most effective immediately following oral ingestions (within 1 hour of ingestion), but may have no benefit once systemic absorption of the toxin has occurred. It is indicated in the following situations:

- Ingestion of a harmful amount of a substance known to be adsorbed by activated charcoal within a time frame in which **adsorption** by charcoal is likely to take place (varies dramatically by substance and situation)
- Unknown substances ingested or presumption of toxic ingestions in high-risk patients

Toxicology reference sources are vague regarding the outer time limits for single-dose activated charcoal administration. Several factors, however, extend the usefulness of activated charcoal beyond the 1-hour window of optimal efficacy:

- Evidence of continued medication absorption demonstrated by increasing serum levels or unexplained continued deterioration in the patient’s clinical status
- Ingestion of enteric-coated or sustained-release preparations
- Ingested drug packets with likelihood of rupture
- Exposure to substances removed through gut dialysis
- Other conditions that delay toxin absorption (eg, food in the stomach and delayed GI motility)

Massive overdoses may require several doses of activated charcoal to adsorb a sufficient amount of toxin in the intestines.

Sedated patients with an unprotected airway are not candidates for activated charcoal treatment. Unresponsive patients needing activated charcoal require definitive airway protection with an ET tube. Aspiration can cause significant morbidity and may be a lethal complication. Vomiting and constipation are frequent side effects of administration.

Activated charcoal is also contraindicated following caustic ingestions, because these chemicals are not adsorbed by activated charcoal and it obscures the views in diagnostic imaging procedures. Likewise, it is contraindicated for patients with hydrocarbon ingestions because of its high aspiration potential. Numerous substances (eg, lithium, iron, certain heavy metals, hydrocarbons, and alcohols) are not well adsorbed by activated charcoal. If these substances are taken simultaneously with toxins that can be adsorbed, however, use of activated charcoal may still confer some benefits. A careful risk-benefit analysis is essential in such cases.

Activated charcoal is often combined with a saline or magnesium-containing cathartic agent to decrease the likelihood of constipation. Consult a Poison Control Center or a reliable toxicology reference to determine the appropriateness of using activated charcoal in unusual poisoning situations.

Multiple-Dose Activated Charcoal

Multiple-dose activated charcoal should be used for substances with delayed absorption. In addition, because of its unique ability to remove chemicals and medications already absorbed into the body, multiple-dose activated charcoal can reduce the elimination half-life of various chemicals, theoretically improving clinical outcomes. Typically, a reduced dose of activated charcoal is administered every 1 to 6 hours for several doses, or for up to 12 hours total. A toxicologist should be consulted for specific dosing recommendations.

Whole-Bowel Irrigation

One additional option exists for treating ingestions of toxic substances that are not amenable to treatment with activated charcoal. **Whole-bowel irrigation (WBI)** requires the patient to drink (or receive via orogastric or nasogastric tube) large quantities of a nonabsorbable, electrolyte-balanced liquid that propels stomach and intestinal contents through the digestive system. WBI is indicated for significant ingestions of potentially toxic substances, substances not well adsorbed by activated charcoal (eg, iron, heavy metals), and substances with delayed absorption. It can be given in combination with activated charcoal when patients have ingested large quantities of sustained-release or enteric-coated medications (eg, calcium channel blockers and theophylline). It is also indicated when patients have swallowed packages containing illicit drugs, as is done by body stuffers and body packers. This procedure is performed in the intensive care unit.

Body packers (people who swallow prepared packages of illicit substances for smuggling purposes) and **body stuffers** (people who hastily swallow packets of illicit substances, often to avoid impending arrest) pose a challenge to health care providers. Body packers are at increased risk because they have ingested large amounts of very concentrated substances. Body stuffers are at increased risk because their swallowed packages are often poorly prepared with unreliable materials and marginal technique. Patients may appear completely asymptomatic, but rapid, unexpected, catastrophic clinical instability will develop if the packaging fails and the chemicals are rapidly absorbed by the digestive tract.

Commercial products for WBI are widely available and are used for other purposes, such as preparation for intestinal surgery and diagnostic procedures. Adult patients receive 1.5 to 2 L/h for 4 to 6 hours or until the rectal effluent is clear. Clinicians may use radiography to assist in the diagnosis or monitoring of radiopaque materials.

Enhanced Elimination

In certain poisoning and overdose situations, treatment with **enhanced elimination** is appropriate. This process replaces or augments the body’s normal method of eliminating, modifying, or breaking down toxic substances. Enhanced elimination should be considered when the ordinary route of elimination from the body is impaired by the overdose or other pathology, or if the patient cannot tolerate the adverse effects of the poisoning because of a preexisting medical condition. Substances that become heavily concentrated in the blood or extracellular fluids and only minimally concentrated in body tissues are more likely to respond to enhanced elimination. In contrast, this process is less likely to successfully remove highly protein-bound medications. Options to enhance elimination of certain toxins may include multiple-dose activated charcoal (discussed previously), urinary manipulation, and various modes of dialysis. A toxicologist or nephrologist should be consulted when considering these interventions.

Urinary Manipulation

Alkalinization of urinary pH promotes the increased excretion of weak acids such as salicylates and phenobarbital. Sodium bicarbonate is added to IV fluids to maintain a urinary pH of 7 to 8.5, usually in amounts of 1 to 2 mEq/kg every 3 to 4 hours. During therapy, fluid volume status, serum pH, and electrolytes (especially potassium and sodium) must be carefully monitored. Hypokalemia is extremely common, so frequent point-of-care testing and/or potassium replenishment during transport, if available, should be considered. Continuous cardiac monitoring is also indicated.

Peritoneal Dialysis, Hemodialysis, Hemoperfusion, and Continuous Renal Replacement Therapy

These modes provide additional options for clinicians in managing a severe poisoning or overdose. CCTPs may be called to transport patients who are receiving these treatments. Such treatments generally cannot be continued during transport and will need to be discontinued or interrupted to safely transport the patient. Specialized training and equipment are required in such cases, and their description is beyond the scope of this text. Patients requiring these services may be transported to tertiary care centers from smaller community facilities and clinics.

Specific Toxicologic Emergencies

Pharmaceutical and Abuse Agents

As noted earlier, patients may experience life-threatening reactions to medications (both prescription-only and over-the-counter agents) and drugs of abuse.

Acetaminophen

Acetaminophen (Tylenol, Paracetamol, APAP) is the drug whose ingestion most commonly results in overdose. This medication is used widely as an analgesic and antipyretic, and it is often found combined with narcotic analgesic and cold-symptom ingredients in prescription and over-the-counter preparations. The presence of these other agents may complicate toxicity from acetaminophen when they are ingested together.

Acetaminophen toxicity is insidious. Toxic signs and symptoms may not manifest until well after the optimal time to administer the known antidote, acetylcysteine. Untreated acetaminophen toxicity can lead to liver failure, liver transplantation, or death.

The diagnosis of acetaminophen poisoning is based on patient history and laboratory analysis. Documentation of time, duration, and nature of exposure is essential. The acetaminophen (Rumack-Matthew) nomogram is useful only for single, acute ingestions; it is not reliable for exposures that have occurred over several hours or days **FIGURE 21-8**. A serum acetaminophen level should be obtained at least 4 hours (but less than 24 hours) following ingestion, and the level and time plotted on the nomogram. The nomogram will indicate whether toxicity is anticipated and treatment is indicated. *Once toxicity is established, measurement of future acetaminophen levels will not assist in clinical management*. The serum acetaminophen level will continue to decline regardless of toxicity. A metabolite actually causes **hepatotoxicity**, but the decreasing acetaminophen level may mislead providers into discontinuing antidote administration prematurely. A toxicologist should be consulted for situations not covered adequately by the nomogram or if treatment questions persist.

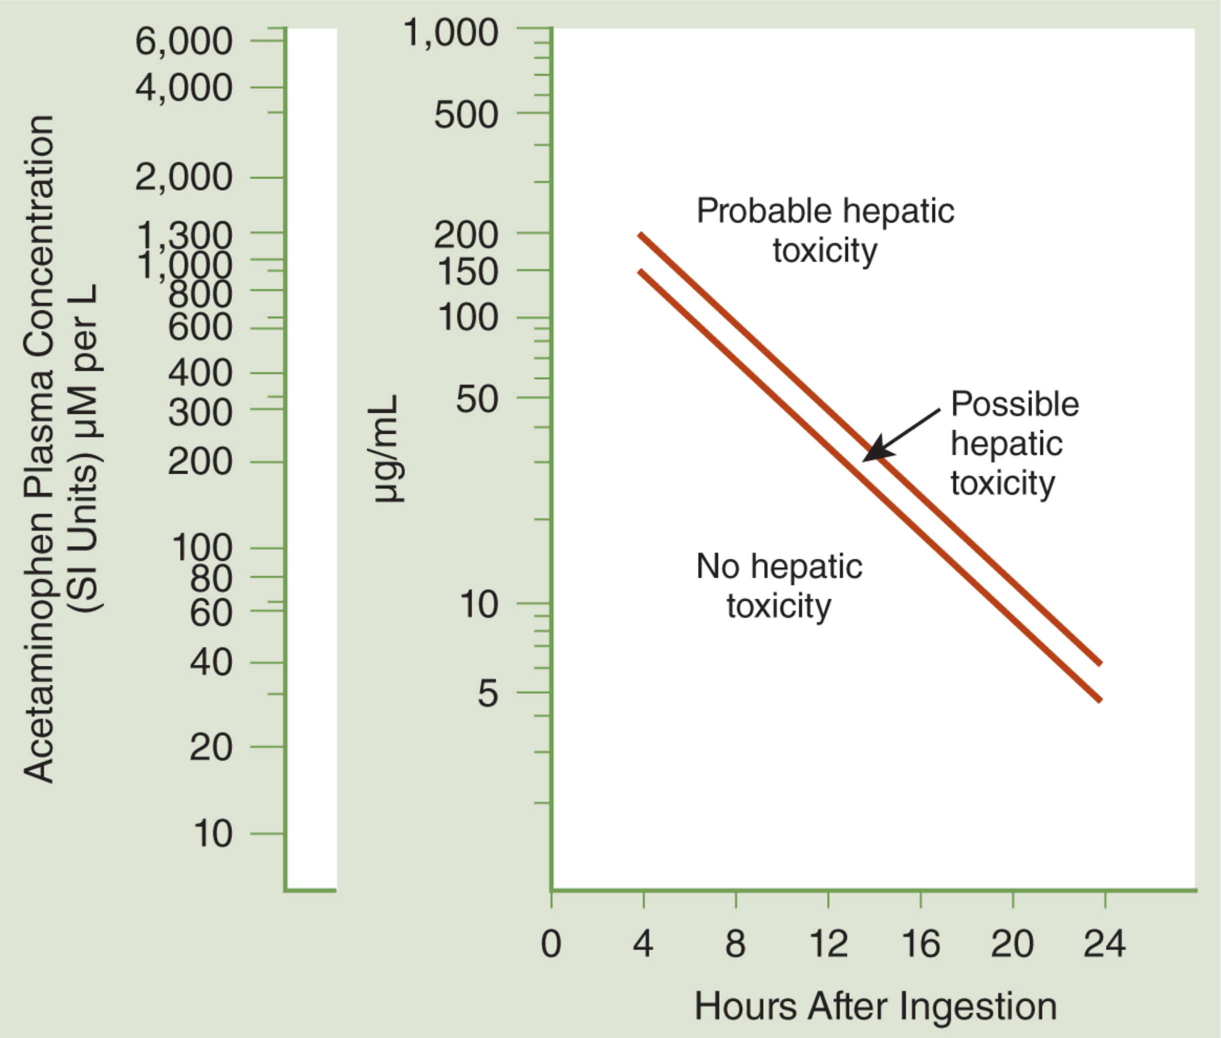

FIGURE 21-8 The acetaminophen nomogram.

Description

Nausea and vomiting are quite common during acetaminophen toxicity. In addition, patients have anorexia, dehydration, diaphoresis, and elevated liver function test results. During subsequent days, abdominal pain (usually in the right upper quadrant), oliguria, hepatomegaly, coagulopathy, and eventual liver failure may develop. A patient who presents with abdominal pain, nausea, or vomiting following a probable acetaminophen overdose should be assumed to have toxicity until proven otherwise.

Acetaminophen toxicity is treated with activated charcoal for initial GI decontamination. Acetylcysteine is the antidote for acetaminophen toxicity and can be given orally or intravenously. This medication decreases the risk of hepatotoxicity to less than 5% when given within 8 hours of ingestion. Although the risk of hepatotoxicity increases if acetylcysteine is started beyond 10 hours after ingestion, it still has benefit for delayed presentations or even in liver failure.

Treatment with acetylcysteine should begin immediately for symptomatic patients presenting more than 8 hours after ingestion. Patients with uncomplicated acetaminophen poisoning are often administered IV acetylcysteine over 21 hours of treatment. A loading dose of 150 mg/kg in 200 mL D_5W (dextrose 5% in water) is administered over 15 to 60 minutes, followed by an IV infusion of 50 mg/kg in 500 mL D_5W over 4 hours, and then a final IV infusion of 100 mg/kg in 1,000 mL D_5W over 16 hours. Fluid and electrolyte abnormalities are possible when pediatric patients receive IV acetylcysteine. Consult a toxicologist or a Poison Control Center for specific IV dosing recommendations beyond 21 hours.

Oral acetylcysteine is given with a 140 mg/kg loading dose, followed by 70 mg/kg every 4 hours for 17 additional doses. Acetylcysteine has a sulfur like odor and is irritating to the GI tract. Even when it is diluted with juice or soda, patients often require aggressive treatment with antiemetics during oral acetylcysteine therapy. Refractory vomiting, from toxicity or related to oral administration of acetylcysteine, often requires IV acetylcysteine.

Signs and Symptoms

Acetaminophen Toxicity

- Early (0 to 24 hours):
    - Nausea and vomiting

    - Anorexia
    - Dehydration
    - Diaphoresis
- Late (24 to 96 hours):
    - Abdominal pain (usually in the right upper quadrant)
    - Elevation of liver function test results
    - Oliguria
    - Hepatomegaly
    - Coagulopathy
    - Liver failure
    - Renal failure (rare)
- Longer than 4 days:
    - Resolution of symptoms or multiple organ failure

Transport Management

Acetaminophen Toxicity

- Manage the ABCs.
- Perform GI decontamination with activated charcoal.
- Administer acetylcysteine (oral Mucomyst or IV Acetadote).

Amphetamines

Amphetamines are available as therapeutic medications (such as methylphenidate [Concerta], amphetamine-dextroamphetamine combination [Adderall], and dextroamphetamine [Dexedrine]); used as illicit stimulants for personal, academic, or professional enhancement; and abused in society for euphoric properties (eg, MDMA [Ecstasy, Molly], methamphetamines). Newer drugs of abuse with similar stimulant effects as amphetamines include synthetic cathinones (bath salts) and synthetic cannabinoids (K2, Spice). These drugs produce many desirable and adverse effects through central and peripheral nervous system stimulation. Frequent users develop tolerance to the psychological effects but not to the physiologic effects, thereby placing them at higher risk for toxicity when they increase their dosage.

Patients who overdose on amphetamines have classic sympathomimetic symptoms (discussed earlier in the chapter). Acute amphetamine toxicity produces hypertension, tachycardia, hyperactivity (although amphetamines are often used in the treatment of hyperactivity disorders), restlessness, anxiety, diaphoresis, tremors, fasciculations, and rhabdomyolysis. Severe toxicity causes seizures, organ ischemia (including but not limited to the cardiovascular, gastrointestinal, renal, and nervous systems), and cerebral hemorrhage. Prolonged use of large quantities of amphetamines may cause a **stimulant washout syndrome** (similar to cocaine washout syndrome, sometimes referred to as a meth crash). In this syndrome, amine stores within the body become depleted following prolonged amphetamine use, leading to excessive sleep, hunger, and depression. Stimulant washout syndrome is completely the opposite of the typical effects of amphetamine use and has features similar to a sedative-hypnotic toxidrome (discussed earlier in the chapter).

Urine drug screening may identify patients taking amphetamines and possibly methamphetamines but often will not detect synthetic analogs (ie, MDMA, synthetic cathinones, synthetic cannabinoids). Serum drug levels are not clinically useful. The patient's urine output and results of blood tests should be monitored for signs of dehydration and rhabdomyolysis.

Gastrointestinal decontamination with activated charcoal or WBI should be considered when clinically appropriate. Treatment of amphetamine overdose is supportive and based entirely on presenting signs and symptoms. Benzodiazepines are used initially for sedation or seizure control. Phenobarbital can be added for prolonged seizures or status epilepticus. Patients with significant hyperthermia should be cooled aggressively. Typical antipsychotics (haloperidol) should not be given because they inhibit cooling and decrease the seizure threshold. Fluids should be replaced by the IV route as clinically indicated. Hypertension that does not respond to sedative medications is treated with vasodilators (IV nicardipine, clevidipine, phentolamine, labetalol). Tachyarrhythmias can be treated with IV esmolol.

Benzodiazepines

Benzodiazepines (eg, diazepam [Valium], midazolam [Versed], and lorazepam [Ativan]) are a group of medications used therapeutically for anxiolysis, sedation, muscle relaxation, and seizure control. Toxicity occurs following therapeutic error, accidental or intentional ingestion, and illicit misuse and abuse in the community. Judicious administration of these agents by health care providers may prevent serious adverse effects when the medications are used therapeutically. Benzodiazepines, even in toxic doses, exert sedative and seizure-protective effects, which are desirable during clinical treatment.

Signs and Symptoms

Amphetamine Overdose

- Hypertension
- Tachycardia
- Hyperactivity, restlessness, and anxiety
- Diaphoresis
- Tremors
- Fasciculations
- Rhabdomyolysis
- Seizures
- Myocardial ischemia
- Cerebral hemorrhage

Transport Management

Amphetamine Overdose

- Manage the ABCs.
- Perform GI decontamination with activated charcoal if needed.

- Administer benzodiazepines for sedation seizure control.
- Administer phenobarbital for additional seizure control, if needed.
- Provide aggressive cooling for significant hyperthermia.
- Replace IV fluids.
- Administer IV vasodilators for refractory hypertension.
- Administer IV esmolol for tachyarrhythmias.

Deaths due to pure benzodiazepine overdoses are rare. Overdoses are often easy to manage conservatively, although sedation and respiratory depression may persist for several days with certain preparations. Benzodiazepine exposure becomes problematic when multiple agents with sedative properties are combined. When benzodiazepines are taken with ethanol, opioids, or other sedative agents, for example, profound CNS and respiratory depression occurs. Toxic effects also include hypothermia, ataxia, and slurred speech. Most urine drug screen tests can detect benzodiazepines that are metabolized to oxazepam (ie, diazepam, chlordiazepoxide [Librium], temazepam [Restoril]) but not benzodiazepines with different metabolites (ie, alprazolam [Xanax], lorazepam, clonazepam [Klonopin], flunitrazepam [Rohypnol]).

Activated charcoal adsorbs orally ingested benzodiazepines, but it is often contraindicated in nonintubated patients with decreased levels of consciousness. Intubation should be considered whenever significant concern arises about a patient’s ability to protect the airway, especially during transport. The majority of patients with benzodiazepine toxicity require only conservative management and careful observation.

Flumazenil (Romazicon), a benzodiazepine antagonist, is an appropriate treatment only for a small minority of overdose situations. Reversal with flumazenil places patients at risk for increased intracranial pressure, sedative withdrawal, increased agitation, and potentially untreatable seizure activity. This medication is contraindicated in patients with poisoning or overdose by unknown substance(s); in patients with a history of seizures; in patients with toxic exposures to chemicals known to cause seizures, increased intracranial pressure, agitation, or CNS stimulation; and in patients taking benzodiazepine medications on a long-term basis. The vast array of situations where flumazenil is contraindicated severely limits its usefulness following benzodiazepine overdose.

Flumazenil is useful when a therapeutic error during procedural sedation requires benzodiazepine reversal in patients without known benzodiazepine dependence. The toxic effects of many benzodiazepines last much longer than the reversal achieved with flumazenil. Thus, unrecognized resedation may occur if patients are not monitored adequately. The adult dose of flumazenil is 0.2 mg IV, increased to 0.3 mg and 0.5 mg at 30-second intervals, up to a maximum dose of 3 mg. Pediatric doses start at 0.01 mg/kg and are titrated up to a maximum of 1 mg total. Flumazenil may be safely used in situations where CCTPs are confident of the patient's clinical status and the substances being treated, such as with overmedication during procedural sedation. Nevertheless, these types of situations may not occur frequently enough in critical care transport to justify routine use of flumazenil by CCTPs.

Signs and Symptoms

Benzodiazepine Overdose

- CNS and respiratory depression
- Hypothermia
- Ataxia
- Slurred speech

Transport Management

Benzodiazepine Overdose

- Manage the ABCs.
- Intubate the patient for airway control and ventilatory support.

Beta-Adrenergic Blocking Agents

Beta-adrenergic blocking agents (beta blockers) are used therapeutically for a wide variety of medical conditions. Toxicity may occur from an intentional or accidental overdose in the community or a profound therapeutic error in a health care facility. Atenolol (Tenormin), propranolol (Inderal), and metoprolol (Lopressor) are widely used beta blockers. These medications inhibit catecholamines both centrally and peripherally. Beta-1 blockers decrease heart rate, myocardial contractility, myocardial conduction, and myocardial oxygen consumption. Beta-2 blockers relax blood vessel walls, constrict bronchi in the lungs, and block catecholamines in the GI and genitourinary tracts. Both beta-1 and beta-2 blockers cause hypoglycemia through inhibition of **glycogenolysis** and **gluconeogenesis**. These medications are prescribed based on their beta-1 or beta-2 blocking actions. During overdoses, beta selectivity is lost, resulting in both beta-1 *and* beta-2 blocking effects.

Patients' responses to overdose with beta blockers largely reflect their preexisting cardiovascular status. The effects of an overdose will be significantly worse if beta blockers are combined with other cardiotoxic substances. In adults, two to three times the therapeutic dose has the potential to be fatal. Importantly, one normal dose for an adult may have catastrophic effects in a small child.

In addition to hypotension, bradycardia, and hypoglycemia, patients with beta blocker toxicity may exhibit bronchospasm, pulmonary edema, conduction disturbances, tachycardia, mental status depression, and even seizures. Gastric lavage may be considered for recent (within 1 hour), significant ingestions, though it is not performed in the transport setting. Activated charcoal should also be considered for recent toxic ingestions (within 1 hour). Atenolol and acebutolol, but not other beta blockers, can be removed by dialysis for enhanced elimination.

Glucagon is a good choice for initial treatment of a beta blocker overdose. When given at increased doses, it exerts positive inotropic and chronotropic effects, although these effects are often transient. An initial dose of 5 to 10 mg IV is followed by an infusion at 1 to 5 mg/h in adults. This treatment requires a significant amount of glucagon—often more than is available to transport teams.

Bradycardia can be treated with IV atropine (0.01 to 0.03 mg/kg) or cardiac pacing but may prove refractory in patients with severe toxicity. Catecholamines, including dopamine, norepinephrine, and epinephrine, are given for refractory hypotension and bradycardia. **Phosphodiesterase** inhibitors (eg, milrinone) have an **inotropic** effect in beta blocker overdoses but should be used only when invasive monitoring technology is available, because they often result in hypotension from peripheral vasodilation. High-dose insulin therapy (given with IV glucose to prevent hypoglycemia) and intravenous lipid emulsions have been reported to improve survival in beta blocker overdoses. Some medical centers have the facilities and personnel available to place these patients on extracorporeal membrane oxygenation (ECMO). A toxicologist or a Poison Control Center should be consulted for guidance in managing these patients during complicated transports.

Signs and Symptoms

Beta-Adrenergic Blocking Agent Overdose

- Hypotension
- Bradycardia
- Hypoglycemia
- Bronchospasm
- Conduction disturbances
- Pulmonary edema
- Possibly seizures, mental status depression, and tachycardia

Transport Management

Beta-Adrenergic Blocking Agent Overdose

- Manage the ABCs.
- Administer activated charcoal (if within 1 hour of ingestion).

- Consider enhanced elimination (for atenolol ingestions).
- Administer IV fluids.
- Administer glucagon.
- Administer IV atropine or use cardiac pacing for bradycardia.
- Administer catecholamines, including dopamine, norepinephrine and epinephrine, for refractory hypotension and bradycardia.
- Administer high-dose insulin (given with glucose).
- Administer intravenous lipid emulsions.
- Consider milrinone when invasive monitoring technology is available.

Calcium Channel Antagonists (Calcium Channel Blockers)

Calcium channel blockers are used clinically to treat hypertension, migraines, cardiomyopathy, and other conditions. These medications include diltiazem (Cardizem), verapamil (Calan), and dihydropyridines (ie, amlodipine [Norvasc], nifedipine [Procardia XL]). They act by blocking the L-type calcium channels to decrease intracellular calcium levels, which results in vasodilation, decreased myocardial contractility, slowed conduction, and decreased heart rate. Other effects associated with calcium channel blocker toxicity include nausea, vomiting, metabolic acidosis, and hyperglycemia. Management of calcium channel blocker overdoses is complicated by the widespread availability of sustained-release preparations.

Gastrointestinal decontamination with activated charcoal should be considered for recent toxic ingestions (within 1 hour). Repeated doses of activated charcoal may also be considered for severe ingestions. Gastric lavage may be an option for recent (within 1 hour) significant ingestions, though it is not performed in the transport setting. WBI may be appropriate when the overdose involves enteric-coated or sustained-release preparations but, again, this procedure is not done by CCTPs.

Hypotension and bradycardia are the most common signs of overdose with calcium channel blockers. These clinical features may evolve as additional medication is absorbed from sustained-release preparations. One tablet is often enough to cause serious toxicity or death in a small child. Any medication taken beyond the therapeutic dose should be considered potentially toxic.

Intravenous calcium salts are the initial antidotes to an overdose with a calcium channel blocker. Adult patients are given calcium chloride 10% (10 mL) or calcium gluconate 10% (30 mL) every 5 to 10 minutes as needed. In severe cases, patients have been given more than 15 g of calcium safely. Intravenous calcium use is controversial in the setting of concurrent cardiac glycoside medication (ie, digoxin) toxicity. Although the older literature describes increased cardiac dysrhythmias and mortality associated with this treatment, the more recent literature does not report the same adverse effects.

Glucagon and catecholamines (dopamine, norepinephrine, epinephrine) are useful in the management of refractory hypotension and bradycardia from calcium channel blocker overdoses. Other therapies may include high-dose insulin therapy, intravenous lipid emulsions, or methylene blue (for amlodipine toxicity). In addition, cardiac pacing may be required for patients with severe, symptomatic bradycardia. Selected phosphodiesterase inhibitors (such as milrinone) improve contractility but often result in systemic vasodilation, limiting their usefulness. Atropine may improve the bradycardia early in the toxicity, but is not generally effective as the calcium channel blocker toxicity progresses further.

Signs and Symptoms

Calcium Channel Antagonist Overdose

- Hypotension
- Bradycardia
- Nausea and vomiting
- Metabolic acidosis
- Hyperglycemia

Transport Management

Calcium Channel Antagonist Overdose

- Manage the ABCs.

- Perform GI decontamination with activated charcoal.
- Administer IV fluids.
- Administer IV calcium chloride or calcium gluconate.
- Administer glucagon and catecholamines (dopamine, norepinephrine, epinephrine) for hypotension and bradycardia.
- Administer high-dose insulin (given with glucose).
- Consider intravenous lipid emulsions for refractory hypotension.
- Perform cardiac pacing for bradycardia.
- Consider milrinone when invasive monitoring technology is available.

Cardiac Glycosides

Cardiac glycosides (digoxin, digitoxin [not available in the United States]) are used therapeutically to achieve heart rate control, for treatment of supraventricular arrhythmias, and to increase contractility in heart failure. Cardiac glycosides are also found naturally in plants such as foxglove, oleander, and lily of the valley.

Peak effects from oral ingestion of cardiac glycosides occur in 6 to 12 hours. Potentially toxic ingestions require 12 to 24 hours of observation before discharge of the patient from the health care facility.

In acute ingestions, patients often have an initial asymptomatic period ranging from minutes to hours due to the delay in peak effects; this period is followed by the development of nausea, vomiting, abdominal pain, lethargy, or confusion. Hyperkalemia is common after acute cardiac glycoside toxicity. Symptoms of chronic cardiac glycoside toxicity are often vague, frequently resulting in misdiagnosis of this condition. Patients may experience nausea, vomiting, and abdominal pain, possibly accompanied by lethargy, confusion, weakness, and/or yellow-green visual disturbance. Hypokalemia predisposes patients who are taking digoxin or digitoxin on a chronic basis to the drug’s toxicity.

Almost any ECG change (with the exception of supraventricular tachycardia) may be present with cardiac glycoside toxicity. Bradycardia and conduction disturbances are common. Serum drug levels are extremely valuable in the diagnosis and management of cardiac glycoside poisoning. The therapeutic level of digoxin is 0.5 to

2 ng/mL, whereas that for digitoxin is 10 to 30 ng/mL. These levels become falsely elevated after patients receive digoxin immune Fab (ovine) (DigiFab) treatments.

Cardiac glycosides are adsorbed in the intestines by activated charcoal. Severe exposures can benefit from administration of multiple-dose charcoal (discussed earlier in the chapter). Gastric lavage is not usually indicated.

The symptomatic bradycardia associated with cardiac glycoside poisoning may respond to atropine early in the toxicity. Transcutaneous or transvenous cardiac pacing increases the incidence of ventricular arrhythmias and is not indicated unless DigiFab is not available.

The hyperkalemia linked to this condition must be corrected promptly, but without the use of calcium. Cardiac glycosides increase the level of intracellular calcium, which in turn increases myocardial contractility (a beneficial effect), but this pathway also leads to the development of digitalis toxicity. Intravenous calcium use is controversial in the setting of concurrent cardiac glycoside medication (ie, digoxin) toxicity. The older literature describes increased cardiac dysrhythmias and mortality with such treatment, but the more recent literature does not report the same adverse effects. Lidocaine and phenytoin may be considered in the management of ventricular arrhythmias.

DigiFab is the antidote for cardiac glycoside overdoses and the preferred treatment for symptomatic bradycardias, ventricular arrhythmias, and hyperkalemia. Dosing is based on the serum drug level and the patient's weight. Severe hyperkalemia, arrhythmias, and renal disease are indications for antidote administration. Consult a toxicologist or a Poison Control Center for specific treatment and dosing recommendations.

Signs and Symptoms

Cardiac Glycoside Overdose

- Nausea and vomiting

- Abdominal pain
- Bradycardia and conduction disturbances
- Hyperkalemia
- Possibly lethargy, confusion, and/or weakness

Transport Management

Cardiac Glycoside Overdose

- Manage the ABCs.
- Perform GI decontamination with activated charcoal (single dose or multiple doses).
- Administer atropine for bradycardia.
- Administer DigiFab for bradycardia, ventricular arrhythmias, or hyperkalemia.
- Administer lidocaine and phenytoin for ventricular arrhythmias.
- Perform cardiac pacing for bradycardia if DigiFab is not available.

Cocaine

Cocaine shares many toxic properties with amphetamines and other sympathomimetics. This potent drug is used therapeutically for anesthesia and vasoconstriction of the mucous membranes, but toxic exposures most often occur following illicit use and abuse. Cocaine is rapidly absorbed via all mucous membranes: the GI tract, lungs, rectum, and vagina. Depending on the route and method of administration, the effects of cocaine peak in 1 to 30 minutes, and the drug has a duration of action up to 140 minutes. Cocaine handlers may hide cocaine internally for smuggling purposes (body packers) or rapidly conceal cocaine internally when arrest is believed to be imminent (body stuffers); thus, their care poses a particular challenge to health care providers.

Diagnosing cocaine toxicity involves obtaining a patient history and performing urine drug screens and a clinical examination. Chest pain is the most common symptom of cocaine intoxication. In addition to myocardial ischemia and infarction, chest pain may stem from cocaine-induced aortic dissection, pneumothorax, and pneumomediastinum. Young patients without a cardiac history, who have an acute myocardial infarction or acute coronary syndrome, should be assessed for the possibility of cocaine use.

Other symptoms of cocaine intoxication involve many body systems. Ventricular and supraventricular tachycardias are common. Hypoxia, acidosis, and sympathetic stimulation contribute to the development of tachycardias. Bradycardia also occurs from vagal stimulation in some situations. Most cocaine-related deaths are ultimately caused by arrhythmias. Additional vascular effects include hypertension and renal or intestinal vasospasm.

Cocaine has significant effects on the CNS. Patients may have cerebral hemorrhage or infarction, coma, anxiety, agitation, delirium, and psychosis. Seizures occur following exposure, but status epilepticus suggests continued absorption or concomitant toxicity.

Other harmful effects from cocaine include hyperthermia, muscle rigidity, various movement disorders, rhabdomyolysis, acidosis, pulmonary edema, and exacerbation of asthma. Patients may exhibit skin alterations such as tissue necrosis, ulcerations, and scratches, sometimes because of scratching imaginary insects. (These signs and symptoms are far from a complete list of the effects of cocaine intoxication.) Heavy cocaine users may experience **cocaine washout syndrome**, which manifests as profound exhaustion due to depletion of their neurotransmitters, but they maintain the ability to regain normal mental status and orientation when aroused.

Activated charcoal and WBI are useful for patients who have orally ingested cocaine-containing packages (ie, body packers or body stuffers). The effects of orally ingested cocaine peak within 60 minutes of consumption. Activated charcoal may theoretically be of benefit if given immediately after ingestion, but any delay drastically reduces its efficacy. Cocaine-containing packages trapped in the digestive tract may require surgical removal if WBI is unsuccessful.

There is no antidote for cocaine overdose. Instead, treatment is supportive and based on the patient’s clinical presentation. Benzodiazepines should be administered for agitation, anxiety, muscle rigidity, and seizure control and have a beneficial effect on hypertension. Hypertension that does not respond to benzodiazepines should be approached with caution. Beta blockers given for hypertension may cause an increase in BP because of unopposed alpha-adrenergic stimulation, although recent evidence has challenged this theoretical caution. The use of a vasodilator medication should be considered instead of a beta blocker, or another approach should be utilized for alpha-adrenergic control.

Cocaine-induced myocardial infarction should be treated with conventional strategies, including thrombolytics (or percutaneous transluminal coronary angioplasty [PTCA] in the hospital in certain cases), with the exception that beta blockers must be withheld to avoid unopposed alpha stimulation leading to severe hypertension. Administration of benzodiazepines, phentolamine, and calcium channel blockers may also mitigate sympathetic tone or vasospasm in patients with cocaine intoxication. Care for cocaine-induced myocardial ischemia includes nitrates, oxygen, and aspirin.

Other treatments for cocaine overdose focus on providing IV hydration adequate to maintain a urine output of at least 3 mL/kg/h, monitoring for rhabdomyolysis, and active external cooling for patients with hyperthermia. Various specialists (eg, in cardiology, neurosurgery, or vascular surgery) should be consulted for any cocaine-related end-organ injury.

Signs and Symptoms

Cocaine Toxicity

- Chest pain
- Tachycardias
- Cerebral hemorrhage or infarction
- Coma
- Anxiety, agitation, delirium, and psychosis
- Seizures
- Hyperthermia
- Muscle rigidity and movement disorders
- Rhabdomyolysis
- Acidosis
- Pulmonary edema
- Exacerbation of asthma

- Skin alterations (eg, tissue necrosis, ulcerations, and scratches)

Transport Management

Cocaine Toxicity

- Manage the ABCs.
- Perform GI decontamination with activated charcoal if needed for oral ingestions, body packing, or body stuffing.
- Administer benzodiazepines for agitation or seizures.
- Administer IV hydration.
- Monitor for rhabdomyolysis; alkalinize the urine with IV sodium bicarbonate if evidence of rhabdomyolysis is present.
- Provide active external cooling for hyperthermia.
- Administer vasodilators for hypertension.
- Administer thrombolytics for cocaine-induced myocardial infarction or transport patients to a health care facility capable of performing percutaneous transluminal coronary angioplasty (PTCA) promptly.
- Administer benzodiazepines, phentolamine, and calcium channel blockers to mitigate sympathetic tone or vasospasm.
- Administer nitrates, oxygen, and aspirin for cocaine-induced myocardial infarction.
- Do not administer beta blockers to patients with recent cocaine ingestion.

Opioids and Opiates

Opioids are the class of chemicals that includes naturally derived opiates (eg, heroin, morphine, and codeine) and newer artificial medications with the same properties (eg, fentanyl and meperidine). These chemicals are widely used for analgesia in modern health care, but are also abused throughout the world for their euphoric properties. Absorption may occur through oral, dermal, lung, IV, and mucosal routes, resulting in a vast range of times of onset, peak effects, and duration of effects. Toxicity is highly variable and is determined by the amount, route and rate of administration, and individual tolerance.

Opioid substances may or may not be detected by routine urine drug screening tests, depending on the particular chemical involved.

Prehospital and emergency department health care providers frequently encounter opioid-intoxicated patients. The diagnosis of opioid overdose is routinely made based on the patient's clinical presentation or when symptoms are reversed by an opioid antagonist such as naloxone.

In opioid intoxication, patients have profound CNS and respiratory depression. The triad of CNS depression, respiratory depression, and pinpoint pupils may lead to a presumptive diagnosis. In addition, patients may exhibit euphoria and dermatologic signs such as needle marks or subcutaneous ulcerations. Hypoxia and death occur from severe respiratory depression or noncardiogenic pulmonary edema in untreated patients. Patients may have more unusual symptoms when exposed to specific opioids, such as seizures with meperidine use and histamine release with morphine use. Manifestations of hypoxic brain injury may further complicate the clinical diagnosis in opioid-intoxicated patients.

In patients with severe opioid overdoses, the airway and breathing are frequently compromised. Consequently, initial treatment involves establishing and maintaining a patent airway while supporting oxygenation and ventilation. Naloxone, when administered promptly, can reverse the opioid effects and often reestablishes a patent airway and spontaneous breathing.

Naloxone is the most commonly used antidote for acute opioid overdose. It can be administered intravenously, intramuscularly, subcutaneously, intranasally, and via nebulization. Dosing is titrated to reverse respiratory arrest or depression without precipitating withdrawal symptoms in long-term users. Because the reversal effects of naloxone do not last as long as the effects of many opioids do, careful monitoring is needed following naloxone administration to avoid an unrecognized return of toxic effects. Naloxone can also be administered as an IV drip to maintain CNS and respiratory functioning in patients with long-acting opioid toxicity.

Treatment with activated charcoal is indicated for patients who have recent oral ingestions of opioid substances, especially when they are combined with other toxic chemicals (ie, acetaminophen), and for patients who have ingested opioid-containing packages (ie, body packers or body stuffers). Following an oral opioid overdose, patients should be evaluated for the presence of acetaminophen and salicylates.

Signs and Symptoms

Opioid Toxicity

- Profound CNS and respiratory depression
- Pinpoint pupils
- Euphoria
- Noncardiogenic pulmonary edema
- Dermatologic signs of needle marks or subcutaneous ulcerations
- Pruritus
- Bradycardia, hypotension

Transport Management

Opioid Toxicity

- Manage the ABCs.
- Administer naloxone to reestablish a patent airway and spontaneous breathing.
- Perform GI decontamination with activated charcoal if needed for oral ingestions, body packing, and body stuffing.

Salicylates

Poisoning from aspirin (acetylsalicylic acid) and other salicylate-containing compounds continues to challenge health care providers. In addition to being present in aspirin, salicylates are found in topical analgesics, liniments, and antidiarrheal agents. Toxic exposure may occur through accidental ingestion by children, due to therapeutic error, and as a suicidal gesture. Ingestion of less than 1 mL of a concentrated topical preparation can cause toxicity in small children.

Diagnosing salicylate poisoning involves obtaining a patient history, performing a clinical examination, and laboratory testing. Serum salicylate levels can be obtained at most health care facilities. Samples should be drawn as soon as possible following exposure, and serial samples should be performed for any toxic ingestions of either regular salicylates or enteric-coated preparations.

A presumptive clinical diagnosis can be made when patients report taking excessive doses of salicylate products and have tachypnea and tinnitus. Any new patient report of tinnitus, dizziness, or deafness should prompt an evaluation for possible salicylate poisoning. Salicylate toxicity can cause a spectrum of neurologic changes, ranging from mild confusion to coma. Nausea, vomiting, abdominal pain, GI bleeding, and hyperthermia may also be present. In severe cases, salicylates may cause pulmonary edema, liver or renal failure, dehydration, electrolyte abnormalities, profound metabolic acidosis (although respiratory alkalosis is also frequently present), and coagulopathy.

Patients with salicylate poisoning require careful attention to the ABCs. Initially, these patients exhibit a CNS-driven tachypnea. As the poisoning evolves, the respiratory rate and depth increase to compensate for worsening metabolic acidosis. For patients who require intubation and mechanical ventilation, their respiratory rate, tidal volume, and minute volume should be matched carefully to avoid undermining their potentially life-saving compensatory hyperventilation. Fluid volume and electrolyte status should be carefully monitored during treatment and transport. Acidosis and subsequent treatments will alter the elimination and distribution of critical electrolytes, such as potassium. Potassium replenishment should be anticipated during patient treatment and transport, especially if urinary alkalinization is performed.

There is no antidote for salicylate poisoning. GI decontamination may include gastric lavage (if the ingestion occurred within 1 hour of presentation), activated charcoal, or WBI for massive ingestions in older children, adolescents, and adults. Depending on the quantity of aspirin or salicylate ingested, patients may require repeated doses of activated charcoal to adsorb the vast quantity of available toxin.

Patients with salicylate toxicity are candidates for treatment with several modes of enhanced elimination. Urinary alkalinization is extremely effective for reducing the salicylate level. This simple procedure can easily be initiated while other interventions are performed or during transport. Salicylate toxicity is also effectively treated in the hospital with hemodialysis or **hemoperfusion**, although hemoperfusion does not provide the same correction of electrolyte levels and acidosis as is delivered by hemodialysis. Indications for hemodialysis include a salicylate level greater than 100 mg/dL, a salicylate level greater than 90 mg/dL with impaired renal function, hypoxemia, altered mental status, and a pH of 7.2 or lower despite bicarbonate therapy. Both hemodialysis and hemoperfusion are performed in the intensive care unit. Use caution when intubating patients with salicylate overdose. A high respiratory rate is needed and blunting the respiratory drive during intubation and ventilation may abruptly worsen toxicity.

Signs and Symptoms

Salicylate Toxicity

- Tachypnea
- Tinnitus, dizziness, or deafness
- Hyperthermia
- Neurologic changes ranging from mild confusion to coma
- Nausea, vomiting, abdominal pain, and GI bleeding
- Pulmonary edema
- Liver or renal failure

Transport Management

Salicylate Toxicity

- Manage the ABCs.
- Monitor fluid volume and electrolyte status.
- Provide potassium replenishment.
- Perform GI decontamination with activated charcoal and consider multiple-dose activated charcoal.
- Perform urinary alkalinization for reduction of the salicylate level.

SSRIs (and Noncyclic Antidepressants)

This category includes medications such as fluoxetine (Prozac), paroxetine (Paxil), sertraline (Zoloft), and a host of others. These medications represent less-toxic alternatives to TCAs for the treatment of depression and anxiety and for smoking cessation.

In general, the toxicity of SSRIs is limited, although severe exposures can cause seizures, serotonin syndrome (discussed earlier in the chapter), cardiovascular alterations, and rarely death. No clear toxic dose has been established. Neither urine nor serum drug screening is widely available to assist in diagnosis or management of SSRI toxicity.

Sedation, ataxia, dizziness, and coma are CNS complications of toxicity seen after SSRI ingestions. Nausea, vomiting, diarrhea, headache, restlessness, shivering, diaphoresis, and sinus tachycardia may also occur. Large ingestions of citalopram (Celexa) and escitalopram (Lexapro) can cause seizures and QTc prolongation leading to torsades de pointes.

There is no antidote for SSRI poisoning or overdose. Gastric lavage and WBI are not typically indicated unless SSRIs are taken in combination with more toxic substances. Activated charcoal is effective for adsorption in the GI tract if given promptly following ingestion (within 1 hour). In SSRI overdose situations in which serotonin syndrome occurs, the treatment is supportive and is based on the patient’s symptoms. Hypotension is treated initially with volume resuscitation. Seizures are treated initially with IV benzodiazepines. Patients’ ABCs need to be carefully monitored in severe overdoses.

Signs and Symptoms

SSRI Toxicity

- Sedation, ataxia, dizziness, and coma
- Nausea, vomiting, and diarrhea
- Headache, restlessness, shivering, and diaphoresis

- Hypotension, QTc prolongation, and sinus tachycardia
- Muscle rigidity, tremors, and hyperreflexia
- Seizures

Transport Management

SSRI Toxicity

- Manage the ABCs.
- Perform GI decontamination with activated charcoal if needed.
- Provide volume resuscitation for hypotension.
- Administer IV benzodiazepines for seizures.

Toxic Alcohols (Ethylene Glycol and Methanol)

The toxic chemicals ethylene glycol and methanol are commonly available in the community and present a significant challenge to health care providers following accidental or intentional ingestion. Each can cause profound, lethal metabolic acidosis following ingestion of even very small quantities. Ethylene glycol is the primary component in vehicle antifreeze; methanol is the primary component in windshield washer fluid and other solvents. Accidental exposure to these chemicals occurs when they are mislabeled or placed in a beverage container. Children may be drawn to the sweet taste of ethylene glycol. People with alcoholism may consume either chemical while searching for an ethanol substitute.

Serum methanol or ethylene glycol levels are usually available only in larger health care facilities. Even in larger tertiary centers, obtaining results for quantitative serum levels may take many hours or several days. The long delay tends to undermine the clinical utility of these tests for diagnosis and management of toxicity.

Clinicians have additional options to assist with diagnosis of ethylene glycol toxicity. Oxalate crystals in the urine are highly suggestive of ethylene glycol poisoning in the right setting. Some laboratory lactate analyzers can cross-react with the ethylene glycol metabolite glycolate to produce falsely elevated lactate levels, sometimes markedly so. If a laboratory has some lactate analyzers that cross-react and other analyzers that do not cross-react with glycolate, the resultant difference in the measured lactates, or lactate gap, can help in the diagnosis of ethylene glycol toxicity. Vehicle antifreeze often has fluorescein added and was previously thought to be visible in urine when viewed under a Wood's (ultraviolet) lamp. However, several studies have shown that using urinary fluorescence is an unreliable technique for diagnosing ethylene glycol ingestion.

Both methanol and ethylene glycol cause an elevated serum osmolar gap—a finding that is very useful for timely diagnosis in outlying facilities. Osmolality is calculated as follows (BUN = blood urea nitrogen):

$$2 \times \begin{array}{l}\text{(Serum}\\ \text{sodium)}\end{array} + \frac{\text{Glucose}}{18} + \frac{\text{BUN}}{2.8} = \begin{array}{l}290\text{m Osm/kg}\\ \text{(Normal)}\end{array}$$

By comparing the calculated serum osmolality with the measured serum osmolality, clinicians can determine the osmolar gap. For a rough estimation of the serum level (mg/dL), the osmolar gap is multiplied by the appropriate conversion factor **TABLE 21-2**.

TABLE 21-2 **Osmolar Gap Conversion Factors**

Substance	Conversion Factor
Ethanol	4.6
Ethylene glycol	6.2
Methanol	3.2
Isopropyl alcohol	6.0

Data from Olson KR, ed. *Poisoning and Drug Overdose*. 5th ed. New York, NY: McGraw-Hill; 2007:32.

When hospital laboratories measure, rather than estimate, serum osmolality, it is essential that they use the “freezing-point method.” Other analysis methods, which may lead to evaporation of alcohols in the specimen, will give inaccurate results. The serum osmolar gap is adjusted for the presence of serum ethanol and is unreliable when the patient has alcoholic ketoacidosis. It is not an exact test, because at least 12 other chemicals or conditions will cause an elevated osmolar gap. Even so, when serum methanol or ethylene glycol levels are not available, this test can assist with diagnosis and guide initial treatment.

Patients who have ingested ethylene glycol initially exhibit ataxia, slurred speech, and lethargy. These signs, which are characteristic of ethanol intoxication 3 to 4 hours after ingestion, are sometimes accompanied by nausea and vomiting. During this time, laboratory analysis will reveal an elevated serum osmolar gap. As the toxicity progresses (4 to 12 hours after ingestion), profound anion-gap metabolic acidosis develops in conjunction with a drop in the serum bicarbonate level. Seizures, cerebral edema, and coma are common. Respiratory manifestations include tachypnea, hyperventilation, and pulmonary edema. Severe exposures lead to renal failure, cardiac arrhythmias, and conduction disturbances. See Chapter 17, *Gastrointestinal and Genitourinary Emergencies*, for a further discussion of acid–base balance.

Patients with methanol poisoning have signs and symptoms somewhat different from those associated with ethylene glycol exposure. During the first several hours, patients exhibit signs of classic ethanol intoxication, which may be accompanied by gastritis, nausea, and vomiting. An elevated serum osmolar gap is also present. Toxicity progresses into a severe anion-gap metabolic acidosis. Some patients can have a latent period ranging from 6 to 30 hours during which the inebriation and GI symptoms resolve. As toxicity progresses, however, patients may report a “snowfield” in their vision, hazy visual disturbance, or blindness. Severe untreated exposures can lead to further CNS depression, seizures, cerebral edema, coma, hypotension, respiratory arrest, and death.

Gastric emptying with gastric lavage (or gastric suctioning) is the only effective method of decontamination for ethylene glycol and methanol poisoning. Unfortunately, gastric lavage or suctioning is often not effective because the toxic alcohols are absorbed very rapidly. Patients require aggressive treatment for the ABCs following severe exposures.

Two equally effective antidotes are available for the treatment of methanol and ethylene glycol poisoning: ethanol and fomepizole (Antizol). Ethylene glycol and methanol need to be metabolized to cause toxicity, and alcohol dehydrogenase is the first step in their metabolism. Both of the antidotes effectively block alcohol dehydrogenase metabolism of ethylene glycol or methanol into their toxic metabolites.

Ethanol, given either orally or intravenously, promotes methanol and ethylene glycol excretion through an alternative metabolic pathway, drastically reducing the metabolic acidosis. Serum levels are titrated to approximately 100 mg/dL (which may be measured in serum or tested at the bedside using a breathalyzer device). Hospital pharmacies may stock IV ethanol preparations. Patients who receive ethanol therapy require close monitoring. Administration of ethanol may cause abnormal behavior, CNS depression, gastritis, pancreatitis, hyponatremia, and hypoglycemia.

Fomepizole, a commercial antidote for ethylene glycol and methanol poisoning, creates the same alternative metabolic excretion pathway that ethanol does. It is significantly more expensive than ethanol but does not require the same depth and frequency of monitoring as ethanol therapy. Fomepizole does not cause CNS sedation and does not require specific serum monitoring. In selected cases, this treatment may cause headache, nausea, vomiting, dizziness, fever, or rash.

Both of these antidotes—ethanol and fomepizole—not only block toxic alcohols' metabolism into their toxic metabolites, but also increase the elimination half-life of the toxic alcohols. When untreated, methanol is metabolized at a rate of 10 mg/dL/h, such that the elimination half-life is 1 to 3 hours for small ingestions and up to 24 hours for large ingestions. Ethylene glycol's elimination half-life ranges from 3 to 9 hours. With antidotal treatment and normal kidney function, the elimination half-life of methanol increases to 30 to 54 hours and that of ethylene glycol increases to 11 to 18 hours.

Enhanced elimination by hemodialysis is the most effective way to rapidly remove the toxic alcohols and toxic metabolites. Hemodialysis will also normalize the patient's acid–base status and electrolyte levels. Indications for hemodialysis include worsening clinical condition, signs of end-organ toxicity (renal failure, vision loss, coma, seizures), severe metabolic acidosis (arterial pH <7.3), and methanol or ethylene glycol level greater than 50 mg/dL. Hemodialysis also removes the antidotes, so ethanol and fomepizole doses will need to be increased after hemodialysis sessions.

Several adjunct therapies can be given to help enhance metabolism of toxic alcohols via normally minor pathways to nontoxic metabolites. Thiamine and pyridoxine can shift ethylene glycol metabolism away from oxalic acid and toward ketoadipic acid and hippuric acid, respectively. Folate or leucovorin (folinic acid) can increase the clearance of methanol's toxic metabolite, formic acid.

Tricyclic Antidepressants

TCAs are highly toxic medications that are frequently prescribed as last-resort antidepressants. These agents are also prescribed to patients for the treatment of chronic pain, neuropathy, and migraines. Toxicity usually occurs from accidental ingestions by young children and intentional overdoses in patients attempting self-harm. The toxic dose is approximately 10 to 20 mg/kg. Any TCA overdose should be considered potentially life threatening.

Signs and Symptoms

Ethylene Glycol Toxicity

- Ataxia, slurred speech, and lethargy
- Nausea and vomiting
- Seizures, cerebral edema, and coma
- Hyperventilation

- Pulmonary edema
- Renal failure
- Cardiac arrhythmias and conduction disturbances

Signs and Symptoms

Methanol Toxicity

- Ataxia, slurred speech, and lethargy
- Possible gastritis, nausea, vomiting
- “Snowfield,” hazy visual disturbance, or blindness
- Hypotension
- Seizures
- Respiratory arrest
- Coma

Transport Management

Ethylene Glycol and Methanol Poisoning

- Manage the ABCs.
- Administer fomepizole (Antizol) or ethanol (oral or IV).
- Consider enhanced elimination with hemodialysis in patients with a worsening clinical condition, renal failure, vision loss, coma, seizures, severe metabolic acidosis (arterial pH <7.30), and methanol or ethylene glycol levels greater than 50 mg/dL.

Any patient admitted to a health care facility for an intentional overdose should be screened for the presence of TCAs. A 12-lead ECG is more sensitive than serum levels and should be performed on any patient with a suspected TCA overdose. A terminal R wave in lead aVR and a terminal S wave in leads I and aVL are indicative of TCA effects **FIGURE 21-9**. Prolongation of the QRS to greater than 100 milliseconds indicates serious TCA toxicity and increases the patient’s risk of seizures and arrhythmias. Patients with TCA toxicity also often exhibit sinus tachycardia. In severe exposures, they can develop ventricular tachycardia or fibrillation, torsades de pointes, and asystole. Hypotension and cardiogenic shock are possible as well.

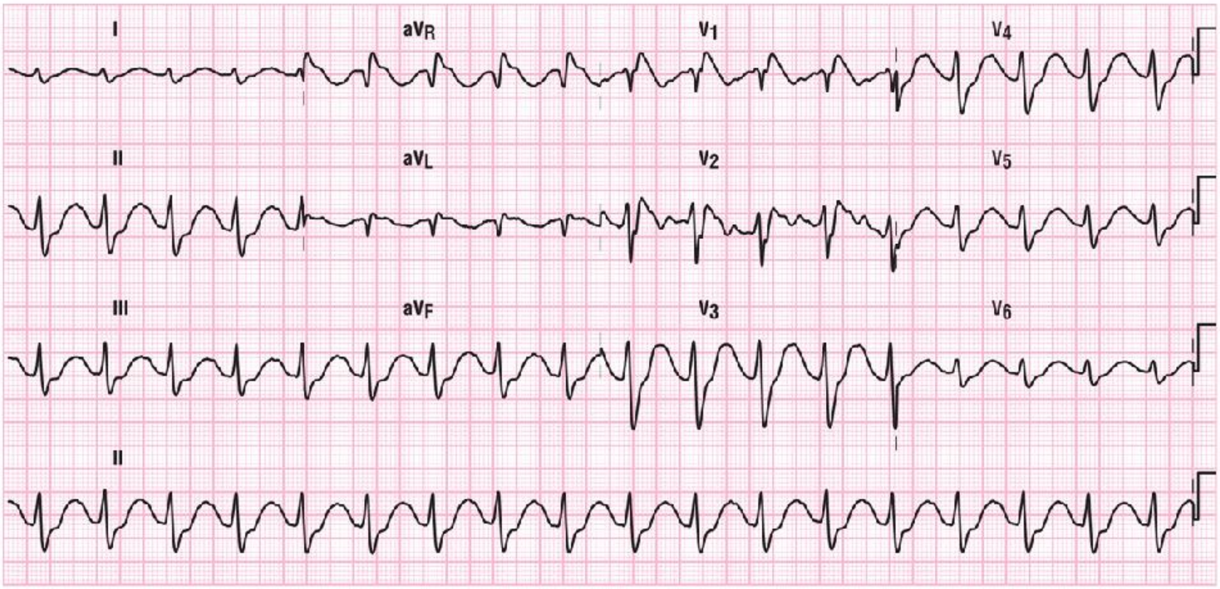

FIGURE 21-9 A 12-lead electrocardiogram for a patient experiencing tricyclic antidepressant overdose. Note the terminal R wave in lead aVR and the terminal S wave in leads I and aVL.

© Jones & Bartlett Learning.

Patients exhibit many anticholinergic signs and symptoms following TCA overdose, but these are usually mild (discussed earlier in the chapter). They should not be treated with physostigmine, as this agent may result in worsening cardiac toxicity.

Ipecac is contraindicated following TCA exposure. Gastric lavage is appropriate for recent large ingestion (within 1 hour). Use of activated charcoal can be considered, but its benefits must be weighed against the risk of aspiration due to concomitant CNS depression.

Patients require aggressive supportive treatment following a TCA overdose. QRS widening or ventricular arrhythmia is treated with IV sodium bicarbonate. Initial boluses of 1 to 2 mEq/kg every 3 to 5 minutes are followed by a maintenance infusion of 150 mEq in 1 L of D_5W to maintain serum pH in the range of 7.50 to 7.55. Hypotension should be treated with 0.9% sodium chloride, sodium bicarbonate, and catecholamines (dopamine, norepinephrine, epinephrine).

Seizures are usually brief and are treated with IV benzodiazepines. Status epilepticus is uncommon.

Signs and Symptoms

Tricyclic Antidepressant Overdose

- Dry mouth and skin
- Dilated pupils
- Seizures
- Delirium, agitation, and hallucinations
- Rhabdomyolysis
- Muscle tremors
- Hyperthermia
- Sinus tachycardia
- Conduction disturbance (QRS widening)
- Ventricular arrhythmias
- Hypotension

Transport Management

Tricyclic Antidepressant Overdose

- Manage the ABCs.
- Administer IV sodium bicarbonate for conduction disturbance, ventricular arrhythmia, or refractory hypotension.
- Administer IV benzodiazepines for seizures.
- Administer IV fluids and/or catecholamines (dopamine or norepinephrine) for hypotension.

Chemical Agents

Acetylcholinesterase Inhibitor (Organophosphate, Carbamate, and Chemical Warfare Nerve Agents) Toxicity

Acetylcholine is a neurotransmitter that is metabolized by acetylcholinesterase. Organophosphates, carbamates, and the chemical warfare nerve agents all block the acetylcholinesterase enzyme, resulting in excess acetylcholine and excessive activation of nicotinic, muscarinic, and CNS receptors. The presence of excessive acetylcholine at muscarinic receptors produces a constellation of symptoms that can be remembered with the mnemonic DUMBELS. Excessive acetylcholine at the nicotinic receptors results in tachycardia, hypertension, dilated pupils, muscle fasciculation, weakness, and paralysis. Excessive acetylcholine in the CNS leads to altered mental status, agitation, coma, and seizure activity.

Both organophosphates and carbamates are used as insecticides. The main difference between these chemicals is that the organophosphates' binding to acetylcholinesterase becomes irreversible over time by a process called "aging," which prevents the regeneration of acetylcholinesterase by the antidote pralidoxime. In contrast, carbamates spontaneously hydrolyze and detach from the acetylcholinesterase enzyme after 24 to 48 hours.

Chemical warfare nerve agents were first developed during World War II and include Tabun (GA), Sarin (GB), Soman (GD), and VX **TABLE 21-3**. The nerve agents are more potent than the organophosphate and carbamate insecticides, with some "aging" very rapidly—within minutes. Despite this difference in acetylcholinesterase inhibition, the clinical presentation of nerve agent toxicity and its management are similar to those for the insecticides.

Exposure to acetylcholinesterase inhibitors can occur through inhalation, dermal and mucous membrane contact, or oral ingestion. In turn, exposed patients pose a major threat to unprotected health care providers during treatment and transport. When patients have experienced dermal exposures, they should be decontaminated with soap and water irrigation or with diluted sodium hypochlorite solution. Health care providers should wear appropriate PPE during decontamination. Any potentially contaminated clothing and jewelry should be removed and secured in a container, as it may carry the toxin and contaminate health care providers or result in continued exposure to the patient. Following an oral exposure, gastric lavage and activated charcoal may be considered to remove acetylcholinesterase inhibitors—but only after securing the patient’s airway with intubation because of the high potential for seizures and aspiration. Gastric contents from gastric lavage or vomiting should be secured in a container, because contact with them may result in exposure to health care providers.

Diagnosis of acetylcholinesterase inhibitor toxicity is based on patient history, similar illnesses experienced by multiple people at the same location, and a physical exam that confirms the cholinergic toxidrome. Laboratory measurement of red blood cells' acetylcholinesterase level is preferred over plasma cholinesterase measurement, but is usually not available rapidly following an acute exposure. M8 and M9 chemical detection paper can be used by responders with special training to identify chemical warfare nerve agents, but have poor sensitivity and specificity for organophosphate toxins. In general, symptoms (DUMBELS or SLUDGEM) are more sensitive indicators of exposure, especially when the patient also develops miosis.

Atropine, pralidoxime (2-PAM, Protopam), and benzodiazepines are the antidotes for acetylcholinesterase inhibitor toxicity. Benzodiazepines are used to control seizures.

Atropine decreases airway secretions. Its initial dose is 0.5 to 2 mg IV, with the dose then being doubled every 5 minutes until the patient's bronchial secretions decrease and adequate oxygenation is achieved. Severe exposures require vast quantities of atropine, which potentially deplete the hospital's and transport team's supplies. Tachycardia is not an indication to withhold additional atropine doses.

Pralidoxime can regenerate acetylcholinesterase activity on enzymes where "aging" has not occurred and will decrease the amount of atropine required as an antidote. The preferred dosing is a bolus of 1 to 2 g administered over several minutes, followed by an IV infusion of 500 mg/h. Pralidoxime can also be administered as 600 mg IM every 15 minutes up to three times if symptoms persist.

Atropine, pralidoxime, and benzodiazepines can be administered intramuscularly in mass-casualty events following a chemical warfare or terrorist exposure. They are stockpiled for these disasters and supplied as auto-injectors.

Signs and Symptoms

Acetylcholinesterase Inhibitor Toxicity

- Nicotinic receptors:
  - Tachycardia
  - Hypertension
  - Fasciculations
  - Weakness
  - Paralysis
  - Dilated pupils
- Muscarinic receptors:
  - SLUDGE: Salivation, Lacrimation, Urination, Diarrhea, Gastroenteritis, Emesis
  - DUMBELS: Diaphoresis/diarrhea, Urination, Miosis, Bradycardia/bronchospasm/bronchorrhea, Emesis, Lacrimation, and Salivation
- CNS:
  - Severe exposures: altered mental status, agitation, coma, and seizure activity

Transport Management

Acetylcholinesterase Inhibitor Toxicity

- Perform decontamination: irrigation with water or saline (combined with a mild soap or detergent if these chemicals are combined with hydrocarbons, which are found in most organophosphate insecticides).
- Manage the ABCs.
- Administer atropine.
- Administer pralidoxime (2-PAM, Protopam).
- Administer benzodiazepines for seizures.

Other Chemical Warfare and Terrorist Agents

Blistering Agents

Blistering agents include sulfur mustard, nitrogen mustard, lewisite, and phosgene oxime. Blistering agents were first developed and used in World War I; more recently, they have been used in Iraq and Syria. These toxicants have a low mortality rate but cause a high number of casualties. Specifically, they create blisters and severe tissue damage and burns on the skin and exposed areas such as the eyes and, if inhaled, cause airway and pulmonary damage. Sulfur mustard causes immediate tissue damage, but its clinical effects may be delayed. Lewisite and phosgene oxime have immediate clinical effects.

Sulfur mustard has a garlic, onion, or mustard odor; exposure to it may be diagnosed with M8 and M9 paper. Lewisite has a geranium-like odor.

Patients who are exposed to blistering agents should be decontaminated with soap and water irrigation. Health care providers should wear PPE suits while decontaminating patients. There is no antidote for the mustards and phosgene oxime, but British anti-lewisite can be used for lewisite exposure. Treatment is supportive, including analgesia, IV fluids, and wound care for chemical burns.

Pulmonary Agents

Pulmonary agents include phosgene, diphosgene, and chlorine. Chlorine has a yellow-green color and carries a “bleach” odor. It was used in World War I and, more recently, in Iraq and Syria. Phosgene and the more potent diphosgene have an odor of freshly mowed hay or green grass.

Chlorine causes immediate pulmonary irritation and can result in acute or delayed pulmonary edema. Pulmonary irritation can be treated with inhaled bronchodilators, corticosteroids, and an inhaled solution of sodium bicarbonate (4 mL of 3.75% to 4.2% solution). Phosgene and diphosgene are less irritating and lead to a delayed onset of pulmonary edema, ranging from 2 to usually 48 hours.

Incapacitating Agents

Incapacitating agents are aerosolized and designed to temporarily prevent normal functioning of the target.

- 3-Quinuclidinyl benzilate (BZ) is a centrally acting anticholinergic agent; exposure to it results in confusion and hallucinations. Physostigmine is a potential antidote.

- Kolokol-1 is a fentanyl analog. It was used by Russian forces during the Moscow theater siege, in which Chechen rebels held patrons hostage. Although naloxone can reverse the opioid effects, overexposure to kolokol-1 can be fatal.

Carbon Monoxide

Carbon monoxide (CO) is a colorless, odorless, tasteless gas that causes serious toxicity and is the number one cause of poisoning deaths. Carbon monoxide is created during the incomplete combustion of carbon-based materials. The most common exposure to CO occurs from motor vehicles, small gasoline engines, stoves, lanterns, burning charcoal and wood, gas ranges, heating systems, and industrial settings where CO from these sources can build up in enclosed or semi-enclosed spaces. Carbon monoxide exposure also occurs intentionally by people attempting self-harm.

CO has an affinity for hemoglobin 200 to 270 times greater than that of oxygen, so its presence in large amounts in the body decreases the amount of oxygen carried by hemoglobin. CO displaces oxygen that is normally bound to hemoglobin, which shifts the oxygen-hemoglobin dissociation curve to the left, decreasing oxygen delivery and resulting in profound tissue and organ hypoxia. In addition, CO exerts direct adverse effects on internal cellular functioning, binding to myoglobin and cytochrome oxidase, preventing the utilization of oxygen, and producing free-radical formation and cellular damage. The decreased oxygen delivery and utilization associated with CO poisoning forces cells into anaerobic metabolism in an attempt to supply the body’s energy needs. Those organs that are highly dependent on the supply of oxygen are the first to exhibit signs of CO poisoning. Specifically, the brain and heart are the primary sites of CO toxicity owing to their large oxygen requirements. The heart may manifest ischemia as chest pain, shortness of breath, arrhythmias, a drop in cardiac output, and, in severe cases, cardiac arrest. The brain may demonstrate its dysfunctional state through headache, mild confusion, altered mental status, seizures, and coma.

CO poisoning should be suspected in any survivor of a fire in a confined space. It can be diagnosed by an elevated CO level in an arterial or a venous blood gas sample. Victims who have been removed after being in a CO-toxic environment for several hours may show low or normal CO levels, despite serious CO poisoning, owing to the half-life of CO on hemoglobin. Measured CO levels do not directly correlate with the severity of symptoms.

The oxygen saturation value is accurate only if it is directly measured in an arterial or venous blood gas sample using CO-oximetry. Values calculated from the arterial partial pressure of oxygen dissolved in the serum or obtained from conventional standard bedside pulse oximetry devices are inaccurate in the setting of CO toxicity and should not be used. Multiwave CO pulse oximetry, however, uses various wavelengths of light to measure carboxyhemoglobin and other values through a noninvasive skin sensor, similar to a pulse oximeter. This device rapidly determines both the CO level and methemoglobinemia (a condition in which the hemoglobin molecule contains a ferric iron [Fe^{3+}] ion) at the bedside and can be used to screen multiple patients following CO exposures. If any doubt exists regarding possible CO exposure, aggressive treatment with 100% oxygen via nonrebreathing face mask should be started before laboratory results are obtained.

Mild CO toxicity results in headache, nausea, vomiting, abdominal pain, and dizziness. Patients without a clear history of CO exposure are at risk of misdiagnosis as having a gastrointestinal virus or colic. Moderate CO toxicity produces confusion, dyspnea, ataxia, tachycardia, and chest pain. Patients with severe CO toxicity have seizure activity, coma, syncope, cardiac arrhythmias, hypotension, and myocardial ischemia. Cherry red skin, a late finding, is usually seen only postmortem. Delayed neurologic signs and symptoms may occur in as many as 20% of CO-poisoned patients; they present 4 days to 4 weeks after exposure with cognitive and emotional deterioration, personality changes, and diffuse demyelination of white matter. Delayed neurologic signs and symptoms are seen more often in older patients and patients with hypotension, coma, or loss of consciousness.

Patients should be removed from any toxic environment before treatment is administered, and precautions need to be taken to prevent exposure of first responders. When CO poisoning is suspected, fresh air should be provided to patients until supplemental oxygen is available. CO has a half-life of 3 to 4 hours in room air, 60 to 90 minutes if 100% oxygen is administered, and 23 minutes in an environment at 3 atmospheres of hyperbaric oxygen. All symptomatic and confirmed patients should continue on 100% oxygen until their symptoms resolve.

Hyperbaric oxygen is usually needed for all symptomatic patients. Continued treatment is indicated in symptomatic patients who have low CO measurements, as hyperbaric oxygen may prevent the development of delayed neurologic sequelae by decreasing cerebral edema and inhibiting leukocyte activation.

Special Populations

Fetal hemoglobin interacts differently with CO than maternal hemoglobin does, and its higher binding affinity for CO places a fetus at greater risk of CO poisoning. Although maternal blood levels of CO will begin to decline immediately after exposure to CO ceases, elimination of CO in fetal blood takes 3.5 times longer to complete. Fetuses are at increased risk of fetal demise and low birth weights when the mother experiences CO exposure. Pregnant patients with CO poisoning are often referred to hyperbaric oxygen therapy.

The airways of patients with altered mental status or seizures in the setting of CO poisoning or patients with airway burns should be actively managed by ET intubation. In preparation for hyperbaric therapy, patients who require ET intubation and have CO poisoning should have the ET tube cuffs filled with water to prevent the cuffs from decreasing in size.

Cyanide poisoning may complicate CO poisoning as a result of fire exposure, because fires that burn polyurethane, acrylonitrile, nylon, wool, and cotton release cyanide. Cyanide poisoning should be suspected in addition to CO poisoning when the patient has an elevated lactate level; treatment in such a case begins with hydroxocobalamin. The nitrites in the cyanide antidote kits should not be used in patients with both CO and cyanide poisoning, because they will induce methemoglobinemia and decrease the amount of oxygen that hemoglobin can carry.

The remaining treatment for CO exposure is supportive. Airway and ventilator support is needed for comatose patients. Seizures should be controlled with IV benzodiazepines. Exposure to other drugs and toxins should be considered in intentional exposures.

The CCTP should consider the source of CO poisoning in any patient, inasmuch as other family members or coworkers may have remained in a poisoned environment. The insidious nature of CO poisoning has prompted safety-conscious prehospital response services to attach personal CO monitors to first-in bags so providers are alerted immediately when they enter a potentially CO-poisoned atmosphere.

CONTROVERSIES

Carbon monoxide is the leading cause of poisoning in every industrialized country, yet as many as 50% of cases continue to be misdiagnosed. Long-term consequences of CO poisoning include a significantly increased incidence of neurologic changes ranging from decreased intelligence, to cognitive, emotional, and personality changes, to Parkinson like syndromes. Because symptoms have little correlation to carboxyhemoglobin (blood CO levels), providers must maintain a high index of suspicion and use noninvasive screening technologies whenever available.

Signs and Symptoms

Carbon Monoxide Toxicity

- Mild: headache, nausea, vomiting, abdominal pain, and dizziness
- Moderate: confusion, dyspnea, ataxia, tachycardia, and chest pain
- Severe: seizure activity, coma, cardiac arrhythmias, hypotension, myocardial ischemia, syncope

Transport Management

Carbon Monoxide Toxicity

- Remove the patient from the toxic environment.
- Provide fresh air.
- Perform CO oximetry.
- Give 100% oxygen immediately; if ventilating, also give 100% oxygen.
- Manage the ABCs.
- Perform ET intubation and provide 100% oxygen; fill the ET tube cuffs with water if hyperbaric treatment is anticipated.
- Administer IV benzodiazepines for seizures.
- Assess for other possible causes of altered mental status or cardiovascular dysfunction.
- Consider concomitant poisoning with cyanide if the patient's lactate level is elevated.

Caustics and Corrosives

Patients may be exposed to caustic agents through occupational and industrial exposures, household contacts, and a vast array of other scenarios. Caustics include acids, alkalis, and many other chemicals, all of which may cause mucosal, skin, or internal organ damage following exposure.

The duration of exposure, concentration, pH, particular substance, and site exposed are all factors that influence the degree of toxicity. Exposure can occur through inhalation, ingestion, or dermal or eye exposure. Systemic toxicity is also possible following exposure through any of these routes. Acidic substances cause coagulation necrosis, which limits the depth and extent of injury, although the acid can still be absorbed. Alkali substances form liquefactive necrosis, allowing for extensive tissue penetration. Hydrocarbons and hydrofluoric acid are discussed separately in this chapter.

Diagnosis is often aided by the patient's reported history or description of the setting where the exposure occurred or the symptoms began. Material Safety Data Sheets and other documents may indicate the particular chemical involved and provide suggestions for treatment, decontamination, and PPE needed for rescuers.

Eye and skin exposures to caustics and corrosives require copious irrigation with saline or water. Prolonged eye irrigation is usually best achieved using a Morgan Lens and topical anesthetic. Irrigation of the eye should continue until the pH is normal or at least 2 L of fluid has been used. Skin exposure is best treated by removing clothing and solid materials first, then using a shower to wash off any remaining materials.

Patients with an inhalation exposure require immediate fresh air. Symptomatic patients may require supplemental oxygen, bronchodilator medications, humidified oxygen or air, or assisted ventilation in severe exposures.

The ingestion of caustic agents has the potential to cause devastating injury. Close monitoring for airway compromise, gastrointestinal bleeding and perforation, and free air in the thorax or abdomen is needed. Immediately after oral exposure, patients should be given a small amount of water or milk to drink to remove the caustic agent from the upper airway. Do not induce vomiting or make any attempt at neutralization. Secure the airway with an ET tube early if the patient has signs of airway injury, because such an injury may progress quickly. The patient should be monitored and evaluated for complications and esophageal or gastric perforation for several days following a significant exposure, if such injuries are not immediately apparent.

Consult a toxicologist or Poison Control Center for treatment recommendations for specific exposures. For example, iodine is a caustic and cytotoxic agent and is more toxic than iodide. Dilution with starch (eg, cornstarch, flour, or milk) will convert iodine to the less toxic iodide and may be recommended.

Phenols cause painless caustic burns and coagulation necrosis, but can also produce systemic symptoms such as bradycardia, hypotension, seizures, and movement disorders. They are sticky, oily, and lipid soluble—characteristics that increase skin penetration. Application of water may spread phenols to other areas, so soapy water, vegetable oil, or low-molecular-weight polyethylene glycol may be recommended as means of decontamination.

Hydrogen peroxide is a very mild mucosal irritant. When concentrations greater than 9% are ingested, however, they can produce large amounts of gas that can be absorbed and result in systemic air embolisms.

Anionic and nonionic detergents can result in minor gastrointestinal irritation if ingested. Cationic detergents are more toxic, resulting in severe gastrointestinal distress. In recent years, the introduction of brightly colored single-use laundry packets or laundry “pods” has created an increased risk of poisoning among children, who may mistake these containers for candy. Biting into these pods delivers a concentrated amount of detergent and has resulted in vomiting, respiratory distress requiring intubation, coma, and seizures.

Transport Management

Caustic and Corrosive Exposure

- Perform decontamination: irrigate the eyes or skin with water or saline (combined with a mild soap or detergent if these chemicals are combined with hydrocarbons).
- Check the mucosal eye pH; ensure the pH is normal before discontinuing irrigation.
- Manage the ABCs.
- For inhalation exposure:
  - Provide fresh air.
  - Administer supplemental oxygen.
  - Administer bronchodilator medications if the patient is wheezing.
  - Administer humidified oxygen or air.
  - Provide assisted ventilation in severe exposures.
- For ingestion:
  - Monitor closely for airway compromise, gastrointestinal bleeding and perforation, and free air in the thorax or abdomen.
  - Immediately provide water or milk to drink.
  - Do not induce vomiting or attempt neutralization.

Chlorine, Ammonia, and Asphyxiate Gases

Various gases have the potential to damage or irritate the mouth, nose, and airway; to displace oxygen in a patient’s lungs; or to otherwise disrupt effective respiration. These substances exist in gas form or become gases through chemical reactions or when a liquid or solid container is somehow compromised. Exposures occur during a hazardous materials release or when adequate safety precautions are not implemented during the use or storage of these chemicals. The toxicity of such gases is highly variable, depending on the gas, its concentration, the duration of exposure, the preexisting health of the exposed people, and myriad environmental factors.

Chlorine gas is used in the production of a variety of industrial and commercial products, as a disinfectant, and to kill bacteria in public drinking water supplies and swimming pools. As noted earlier, chlorine is also used as a chemical warfare/terrorist agent. In addition, chlorine can be produced inadvertently in the home by mixing an acid cleaner with bleach; a similar compound, chloramine, is produced by mixing ammonia cleaner with a bleach cleaner. Chlorine has the odor of bleach and, when present in concentrated amounts, is yellow-green in color. This water-soluble chemical forms hydrochloric acid on contact with water. Upon dissolving in the water in the eyes, mucous membranes, and airway, it immediately causes irritation. Patients present with airway irritation, coughing, burning, and, in severe cases, wheezing, shortness of breath, and pulmonary edema. Nebulized beta agonists and steroids can be used to counteract these effects. Severe symptoms often respond to neutralization of the hydrochloric acid using a half-strength preparation of sodium bicarbonate (4 mL of 3.75% to 4.2% solution) administered by nebulizer

Ammonia is also a water-soluble irritant gas with a unique, pungent odor. It is used in a variety of industrial processes, released from fertilizer tanks and animal waste, found in household cleaners, and commonly used in the illicit manufacture of methamphetamine. Ammonia dissolves in water in the mucous membranes, thereby forming an alkali solution that results in irritation of the eye, nose, and throat; coughing; and shortness of breath. Treatment is primarily supportive, consisting of oxygen and beta agonists.

Nitrogen oxides are produced by burning fossil fuels, but acute toxicity can occur from ice-making (Zamboni) machines on ice rinks, gas stoves, welding, and farm silos. Nitrogen oxides are water-soluble and penetrate deep into the lungs, resulting in injury there. Care for acute exposure is supportive, but be aware that symptoms may be delayed.

Asphyxiate gases displace oxygen; they include nitrogen, helium, neon, argon, methane, propane, and carbon dioxide. These gases are relatively inert, and exposure to them does not result in tissue damage, metabolic effects, or systemic toxicity. Nevertheless, toxicity-related symptoms may include fatigue, increased rate of breathing, nausea and vomiting, loss of consciousness, seizures, and death. Treatment consists of removing the person from the environment, providing oxygen, and offering other supportive measures.

Hydrogen sulfide gas is produced from the decomposition of organic matter. It can be encountered in oil wells and petroleum refineries, is commonly released in wastewater treatment plants, and collects in enclosed septic systems. This gas smells like rotten eggs and is a respiratory irritant. Like cyanide, it combines with Fe^{3+} on cytochrome AA3, inhibiting cellular energy use. Patients who are exposed to hydrogen sulfide are usually overcome by the gas and present with CNS depression and acidosis. Frequently, first responders are also overcome when they enter the enclosed area. To avoid becoming casualties, rescuers should wear SCBA when entering the area. Treatment for patients exposed to hydrogen sulfide gas consists of high-concentration oxygen—a measure that can reverse the binding of hydrogen sulfide to cytochrome AA3. Depending on the duration of exposure, patients may develop pulmonary edema and sustain permanent anoxic injury.

Cyanide

Cyanide is used in several manufacturing processes, such as paper, textiles, and plastics manufacturing; it is also used for electroplating, cleaning metal, developing photographs, and fumigating or exterminating rodents. This gas is released from some plants, such as almonds, apricot pits, and cassava. In addition, cyanide is produced when synthetic materials such as wool and plastics are burned. Artificial nail removers containing acetonitrile release cyanide as well. German authorities used cyanide in World War II concentration camps to exterminate prisoners; this poison has also been used by other combatants as a chemical warfare agent. Finally, cyanide has been used in both homicides and suicides.

Signs and Symptoms

Chlorine, Ammonia, and Asphyxiate Gases Toxicity

- Lacrimation, coughing, and drooling
- Airway discomfort, swelling, and irritation
- Labored, rapid, or absent breathing
- Wheezing
- Pulmonary edema

Transport Management

Chlorine, Ammonia, and Asphyxiate Gases Toxicity

- Manage the ABCs.
- Provide fresh air.
- Administer supplemental oxygen.
- Administer bronchodilator medications for wheezing.
- Administer humidified oxygen or air.
- Provide assisted ventilation in severe exposures.
- Chlorine exposure: administer a half-strength preparation of sodium bicarbonate by nebulizer (half-strength or 3.75% sodium bicarbonate mixed with saline).
- Administer IV corticosteroids in refractory cases.

Cyanide is a rapid-acting cellular poison that exists as either a colorless gas (hydrogen cyanide) or a solid form (sodium cyanide or potassium cyanide). Although it may have an odor of “bitter almonds,” 40% of people cannot detect this odor. Moreover, rescuers should not attempt to identify any exposures through smell and risk their exposure to hazardous materials.

Cyanide exposure can occur though inhalation, ingestion, or transdermal routes. Toxicity is very fast, occurring within seconds to minutes after inhalational exposure, though it may be more delayed with exposure via other routes. Cyanide exposure should be considered in any survivor of smoke inhalation, especially one who has an elevated lactate level.

Cyanide has a high affinity for Fe^{3+}. It causes toxicity by blocking normal energy utilization in the mitochondria. Cyanide binds to Fe^{3+} on cytochrome AA3, blocking this last step in the electron transport chain. Normal cellular energy use is then prevented, efficient production of adenosine triphosphate (ATP) is blocked, and the cells are forced to rely on the relatively inefficient use of anaerobic energy, which generates lactic acid as a by-product. Overall, this process results in clinical signs of hypoxia but without any decreases in pulse oximetry ($PO_{2)}$. Initial symptoms of cyanide poisoning include dizziness, headache, nausea and vomiting, rapid breathing and heart rate, restlessness, and weakness. They are followed by seizures, loss of consciousness, hypotension, bradycardia, respiratory failure, and death.

When cyanide toxicity is suspected, rescuers should wear appropriate protective suits and SCBA during extrication operations. Copious irrigation with soap and/or shampoo and water should be performed to decontaminate patients. Rescuers should also protect themselves against oral exposures, because the emesis of patients may contain cyanide and contaminate rescuers.

Cyanide poisoning is confirmed by measurement of serum cyanide and thiocyanate levels. These results are not routinely available, however, and treatment should not be delayed for a confirmatory test. Rather, treatment should be started immediately upon recognition of the first signs of toxicity.

Several kits to counteract cyanide exposure are available **FIGURE 21-10**. Nithiodote contains sodium nitrite and sodium thiosulfate. The sodium nitrite induces methemoglobinemia. The methemoglobin is able to bind cyanide, pulling it off cytochrome AA3 and reversing toxicity. Sodium thiosulfate complexes with the cyanide on the methemoglobin, removing the cyanide and helping to eliminate the cyanide in a nontoxic form into the urine.

CYANOKIT®
(hydroxocobalamin for injection)

5 g per vial

For Intravenous Use

Rx Only

Manufactured by
Merck Santé s.a.s.
Semoy, France

FIGURE 21-10 Cyanide antidote kits are available commercially and may already be present at industrial, laboratory, and manufacturing settings.

CYANOKIT is a registered trademark of SERB Sàrl, licensed to BTG International Inc.

Nithiodote has now been mostly replaced as a cyanide exposure treatment by the Cyanokit, which contains hydroxocobalamin. Cyanide has a high affinity for cobalt (Co^{2+}), which is found on hydroxocobalamin. Cyanide binds to the Co^{2+}, forming cyanocobalamin and removing it from the Fe^{3+} on cytochrome aac3, which reverses the cyanide toxicity. The dose in adults is 5 g given over 15 minutes; in pediatric patients, it is 70 mg/kg given intravenously over 15 minutes. The main adverse effects of hydroxocobalamin are flushing, temporary red skin and urine, increased BP, and interference with some colorimetric testing and pulse oximetry. Administration of sodium thiosulfate, which is included in the Nithiodote cyanide antidote kit, may have some synergistic effect with the hydroxocobalamin in eliminating cyanide. Cyanide toxicity should be suspected in all patients with significant smoke inhalation, especially those with lactic acidosis, and treatment initiated empirically.

Hydrocarbons

Hydrocarbons are organic compounds used in solvents, fuels, paints, and oils and for many household, commercial, and industrial purposes. Depending on the type of hydrocarbon, they can cause toxicity directly in the lungs or may be absorbed across the lungs or GI tract and result in systemic toxicity. Inhalation is the most common route of absorption for these compounds. The ringed or aliphatic hydrocarbons are able to cross the alveoli in the lungs and can be absorbed systemically. GI absorption is more likely with smaller hydrocarbons. Skin exposure usually results in minor systemic absorption but can cause local tissue injury.

Toxicity typically follows an oral ingestion of a hydrocarbon in which the hydrocarbon also enters into the lungs. Although the various hydrocarbons have different properties, those with high volatility, low surface tension, and low viscosity are most likely to enter the lungs following an oral ingestion. Most toxicity occurs in children who ingest lamp oil, kerosene, lighter fluid, or paint thinner.

Signs and Symptoms

Cyanide Poisoning

- Dizziness

- Weakness
- Headache
- Air hunger
- Acidosis
- No decrease in pulse oximetry or PO_2
- Hyperventilation
- Respiratory depression
- Pulmonary edema
- Complete respiratory failure
- Confusion
- Anxiety
- Seizures
- Complete cardiovascular collapse
- Hypertension or hypotension
- ST-segment and T-wave ECG changes
- Asystole or other conduction blocks and arrhythmias

Transport Management

Cyanide Poisoning

- Perform skin decontamination: copious irrigation with soap and/or shampoo and water.
- Manage the ABCs.
- Administer hydroxocobalamin (Cyanokit).

Hydrocarbons alter the lipid surfactant, a substance that is important to keep the alveoli of the lungs open. Thus, following an oral exposure, a patient may present with cough, shortness of breath, wheezing, and hypoxia. Systemic absorption through the lungs and GI tract can result in CNS depression. Induced vomiting or gastric lavage should be avoided, as both may increase the exposure to the lungs. Treatment is primarily supportive, including oxygen, bronchodilators, and steroids for wheezing and intubation for hypoxia and CNS depression.

Dermal or ocular exposure to hydrocarbons will cause local irritation, burns, or corneal injury. Patients may experience profound chemical burns when hydrocarbon-saturated clothing or footwear is not promptly removed and skin decontaminated. A mild soap or shampoo should be used when irrigating hydrocarbon-contaminated skin.

Solvent abuse is the sniffing of volatile hydrocarbons. Common commercial products such as glues, gas, paint thinners, nail polish removers, adhesives, and cleaning products may contain hydrocarbons and are easily obtained by solvent abusers. These hydrocarbons, when introduced to the lungs, cause dizziness, drowsiness, slurred speech, and unsteady gait.

Trichloroethylene is a halogenated hydrocarbon associated with sudden sniffing deaths. It sensitizes the myocardium to catecholamines, resulting in arrhythmias. Consequently, administration of catecholamines should be avoided in patients who have experienced such exposures. Chronic toluene use results in a renal tubular acidosis, hypokalemia, and severe muscle weakness. Potassium supplementation may be needed for chronic toluene users. Otherwise, treatment for solvent abuse is primarily supportive, consisting of oxygen and intubation for hypoventilation and CNS depression.

The most common types of mothballs are hydrocarbons; they include paradichlorobenzene, naphthalene, and camphor. Paradichlorobenzene is considered nontoxic and is the form most commonly used in households. Naphthalene can cause hemolysis in patients with glucose-6-phosphate dehydrogenase deficiency but is nontoxic in most other patients. Camphor can cause seizures. Although camphor has been removed as an ingredient of mothballs from the US market, it is still found in some imported products.

Transport Management

Hydrocarbon Toxicity

- Manage the ABCs.

- For oral exposures, avoid inducing vomiting, as it may increase pulmonary exposure and toxicity.
- Intubation may be required for patients with CNS depression.

Hydrofluoric Acid

Hydrogen fluoride (HF) is used in semiconductor manufacturing and glass etching, and as a rust remover, vehicle wheel cleaner, and stain remover to clean metal and remove graffiti on walls. Toxicity and time of onset of symptoms from HF poisoning depend on the concentration and duration of exposure. Highly concentrated formulations cause rapid onset of symptoms, while symptoms from low prolonged exposures may present several days later. HF is a relatively weak acid, but it penetrates into the skin; there, the fluoride ion complexes with cations such as calcium and magnesium, resulting in local tissue damage and, in some cases, systemic hypocalcemia.

The fluoride in HF leaches calcium and magnesium from body tissues, resulting in profound and often lethal hypocalcemia and hypomagnesemia. Fluoride also poisons many cellular transport systems, including the Na^+/K^+-ATPase transporter, leading to massive release of intracellular potassium into the systemic circulation. In turn, rapid clinical deterioration of HF-exposed patients may occur unexpectedly. Poisoning by ammonium bifluoride has a presentation and treatment approach similar to that of HF.

Many interventions following HF poisoning are quite unusual and require individualized guidance. Consult a toxicologist or a Poison Control Center for specific treatment decisions about HF exposure.

HF may cause throat discomfort, bronchospasm, stridor, and local airway injury following inhalation. Lung auscultation reveals wheezes, rhonchi, or rales. Serious inhalation exposures can cause delayed chemical pneumonitis or pulmonary edema. Some sources suggest using a nebulized calcium gluconate solution for treatment.

Eye exposure requires thorough and copious irrigation. Early ophthalmologic consultation and evaluation is essential following ocular HF exposure.

Dermal exposure also requires copious irrigation. Potentially contaminated clothing should be removed. Rescuers must use adequate PPE to protect against accidental contact with HF during decontamination.

The ingestion of HF may cause vomiting, abdominal pain, and gastritis, in addition to profound systemic toxicity. Ingestions of large amounts or concentrated solutions of HF are often lethal. If available, immediate stomach evacuation with a nasogastric tube or an orogastric tube should take place. Patients should also immediately ingest a calcium- or magnesium-containing substance such as milk, antacids, magnesium citrate, or magnesium hydroxide. Do not induce vomiting. Likewise, there is no benefit to using activated charcoal, and its presence may obscure a subsequent endoscopic evaluation of the gut.

Most exposures occur on extremity digits when low-concentration HF solutions are used without gloves or there is a break in a glove during industrial or commercial uses. Prolonged low-concentration exposure usually results in a delayed presentation of pain and tissue injury. Patients present with severe throbbing pain at the sites of exposure, with such pain often arising before evidence of local tissue injury becomes apparent.

Treatment for local toxicity includes immersion of the extremity in a high-concentration calcium chloride solution, or application of such a solution to the affected area. Patients may be treated with local IV, intra-arterial, subcutaneous, or dermal calcium administration. This solution is made by dissolving 10% calcium gluconate solution in three times the volume of a water-soluble lubricant (eg, K-Y Jelly). For exposures to the fingers, place the solution into a glove and then put the filled glove over the hand. If this treatment is ineffective, intra-arterial calcium gluconate can be used to perfuse a high concentration of calcium to the affected extremity. Calcium chloride should not be used for subcutaneous or intra-arterial administration. Distal extremity involvement should prompt consultation with a hand surgeon or other appropriate specialist.

High-concentration HF exposure results in immediate severe pain, but the tissue destruction and burns may not become evident for several hours. Large exposures or small exposures with highly concentrated formulations may result in systemic toxicity from hypocalcemia. This may present as tetany, Chvostek sign (facial twitching with tapping of the facial nerve) or Trousseau sign (muscle contraction with inflation of a BP cuff), prolonged QT interval, or cardiac arrhythmias.

Systemic clinical manifestations and arrhythmias from hypocalcemia are treated with intravenous calcium and magnesium. Systemic toxicity requires aggressive replenishment of calcium. Administer calcium gluconate or calcium chloride to any patients with impending or documented hypocalcemia or hyperkalemia, and repeat this treatment as necessary. Multiple grams of IV calcium or a calcium infusion may be required. Monitor serum magnesium levels, and replenish magnesium as indicated. Treat hyperkalemia as necessary with calcium, insulin, dextrose, sodium bicarbonate, and inhaled beta-2 agonists.

Signs and Symptoms

Hydrogen Fluoride Toxicity

- Severe throbbing pain at the site of exposure
- Tissue damage, which may present late
- Hypocalcemia (often severe)
- Hypomagnesemia
- Hyperkalemia

Transport Management

Hydrogen Fluoride Toxicity

- Perform eye and skin decontamination: copious irrigation.
- Manage the ABCs.
- For ingestion exposure:
    - Provide immediate stomach evacuation with a nasogastric or orogastric tube.

  - Administer a calcium- or magnesium-containing substance such as milk, antacids, magnesium citrate, or magnesium hydroxide.
- For skin exposure:
  - Administer calcium gluconate or calcium carbonate gel.
- Administer calcium gluconate or calcium chloride for impending or documented hypocalcemia or hyperkalemia.
- Monitor serum magnesium levels and replenish as necessary.
- Administer calcium gluconate or calcium chloride, insulin, dextrose, sodium bicarbonate, and inhaled beta-2 agonists for hyperkalemia.

Highly Toxic Substances

A vast array of toxic medications and chemicals are discussed throughout this chapter. The topics in this chapter may appear random, but each substance has been included for one of three reasons:

1. The substance may be frequently encountered in the critical care transport environment.
2. Exposure to the substance may require a specialized or unusual approach to treatment.
3. The substance may be highly toxic in very small quantities, requiring greater attention when exposure is suspected.

CCTPs should be aware that a variety of substances could cause serious illness or death in very small quantities, especially in children **TABLE 21-4**.

TABLE 21-4 **Substances Highly Toxic to Children (One-Pill Killers)**

Prescription Medications
Calcium channel blockers
Tricyclic antidepressants (TCAs)

Prescription Medications

Antimalarials

Opiates (eg, codeine, hydrocodone, methadone, fentanyl patch)

Sulfonylureas

Class 1 antiarrhythmic agents

Over-the-Counter and Household Products

Camphor

Oil of wintergreen and other topical salicylates
Liquid nicotine

Selenium dioxide

Data from Karb R. Toxicology: one pill (or sip) can kill. American College of Emergency Physicians website. https://www.acep.org/how-we-serve/sections/toxicology/news/march-2016/one-pill-or-sip-can-kill/. Accessed April 29, 2021.

Hazardous Materials Response

Hazardous materials (hazmat) incidents pose challenges to emergency responders and health care providers for a variety of reasons **FIGURE 21-11**. These scenes may be in remote, almost inaccessible, locations or in dangerous proximity to major population centers, posing an immediate threat to the health and safety of a community. In many cases, numerous chemicals are released simultaneously. Identification, isolation, and mitigation of a hazardous materials release is often hampered by inadequately prepared responders or a limited number of trained and available emergency responders. In addition, weather, terrain, and other environmental factors may complicate conventional disaster response plans. CCTPs should expect involvement in these incidents as emergency responders, through inadvertent contact, or while performing evacuation and interfacility patient transports.

FIGURE 21-11 Hazardous materials scenes pose challenges to providers because of the substances involved and the potential effects on the community.

© Jones & Bartlett Learning.

CCTPs' Role at Hazardous Materials Scenes

Unless CCTPs receive specific training in hazmat response, their role on the scene may be quite limited. Hazmat scenes often involve mechanical extrication, fire suppression, chemical spill containment, population evacuation, crowd and traffic control, the use of complicated PPE, comprehensive primary decontamination, and so forth—skills that CCTPs may be ill prepared to perform without specialized training and equipment. These skills are well beyond the scope of this text.

CCTPs without specialized training or equipment should remain well outside the "hot" and "warm" zones **FIGURE 21-12**, where provider exposure to toxic substances is possible. The areas and shapes of these zones will vary dramatically based on the chemicals involved, wind direction, topography, and other factors. CCTPs can quickly switch roles from rescuer to patient if the wind changes and they are not appropriately positioned and wearing the necessary PPE.

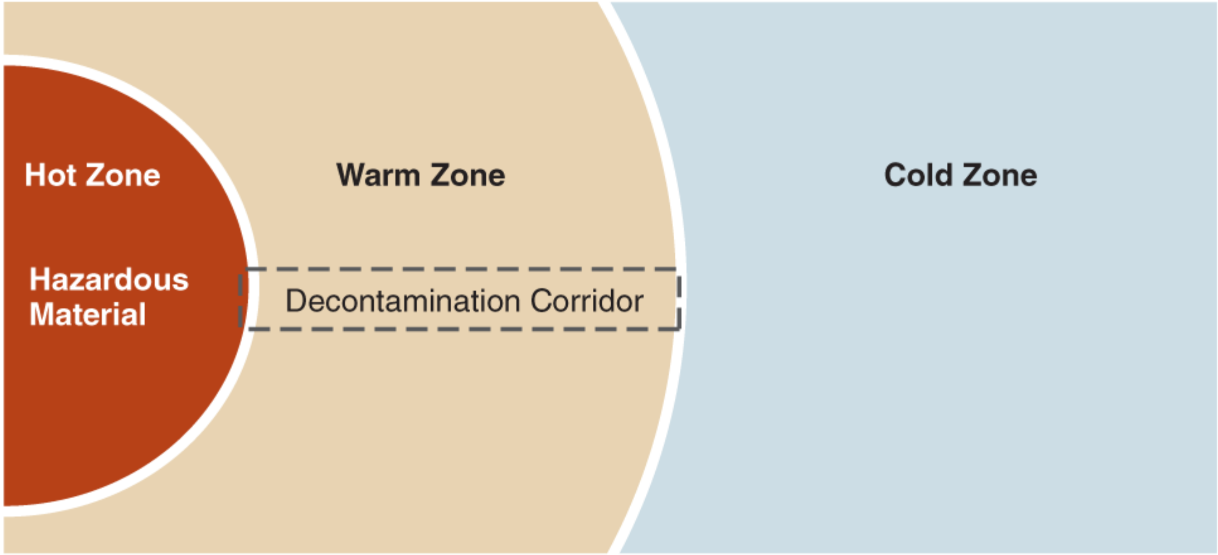

FIGURE 21-12 Configuration of a hazardous materials scene.

© Jones & Bartlett Learning.

CCTPs should be prepared to evaluate decontaminated patients delivered by hazmat team personnel. It is imperative that CCTPs collaborate with hazmat team personnel to determine which substances are potentially involved and which PPE is appropriate for health care providers during treatment and transport. Poison Control Centers and CHEMTREC can provide invaluable assistance to responders if reliable on-site reference materials are not available.

Hazardous Materials Contact Information

- American Association of Poison Control Centers: 1-800-222-1222, www.aapcc.org
- CHEMTREC: 1-800-262-8200, www.chemtrec.com

CCTPs may also be called on to assist members of the hazmat team or other emergency responders directly. These personnel often become ill or injured during the course of on-scene operations. For example, wearing comprehensive PPE can easily cause heat-related illnesses and dehydration, especially during unfavorable environmental conditions, such as on a hot day with a long walking distance from the staging area to the working area. Fires, falls, traffic incidents, and equipment-related activities all create the potential for trauma to emergency responders. Inadequate PPE for hazmat personnel and incorrect decisions related to the staging area or evacuation can place anyone on the scene at increased risk of toxic chemical exposures.

The main objective of CCTPs at hazmat scenes should be to assess and ensure personnel safety during patient care and transportation. Patient assessment and treatment must occur only after personnel safety has been addressed. Rescuers may needlessly place themselves at risk while attempting to resuscitate a patient who has no chance of being revived. As stated earlier in the chapter, inadequate decontamination on the scene exposes CCTPs to toxic chemicals and compromises the safety of the transport vehicle.

Transport Considerations

Once adequate patient decontamination has been performed and other safety concerns have been addressed, patients should be transported to the closest appropriate health care facility. A small community hospital may be the facility closest to a hazmat incident, but often cannot provide adequate treatment for a critically ill patient requiring complex interventions. For example, a small community health care facility may not have sufficient quantities of antidotes or many of the infrequently used antidotes. CCTPs should consider bypassing such a facility in favor of a larger tertiary center when the risks of a longer transport time are outweighed by the benefits of access to greater health care resources.

CCTPs should carefully monitor for the following situations during patient transport:

- Deterioration in the patient’s clinical condition as the toxic exposure evolves
- Signs of inadequate decontamination
- Any interventions appropriate for the patient’s clinical situation, within the ability of the transport team, that have not been already performed

Any indications of inadequate primary decontamination warrant prompt correction of that condition. Unusual smells or fumes in the transport vehicle, unexplained symptoms experienced by transport personnel, and new knowledge about the suspected toxic chemical may require immediate aircraft landing, vehicle evacuation, or donning of additional provider PPE.

During patient transport, CCTPs should provide an adequate report to the receiving facility, including the aforementioned elements. In addition, they should thoroughly and accurately document the patient’s condition, the interventions performed, and patient status or events during transport. Crews should weigh the benefits of providing a hazmat container to the receiving facility staff (for substance identification purposes) against any additional risks posed by transporting this container. A common gasoline container provides minimal benefit but poses a high risk; in contrast, a tightly sealed container of an unusual substance that is not highly toxic may greatly improve subsequent patient care while posing negligible increased risk. Every situation requires special consideration.

Radiation Emergencies

The threat of radiation exposure or a nuclear incident is ever present in our modern society. Ionizing radiation is capable of causing injury from the release of heat generated by a controlled or uncontrolled reaction. It is important to evaluate the nature of a particular radiation event to determine if it poses any risk to emergency responders and health care providers. Radiation releases may occur in health care, industrial, or laboratory settings; during transportation and disposal of radioactive materials; and following a military or terrorist event.

The approach to the treatment of a potentially exposed patient hinges on the distinction between **irradiation** and **contamination**. Health care providers and emergency responders are not placed at any risk by irradiated patients. In contrast, patients with radioactive contamination are likely to spread this material and expose others to radiation. Irradiation will continue to occur until the contaminating materials are contained or otherwise removed. The use of a radiation detection device **FIGURE 21-13** can help responders identify which patients are contaminated with radioactive particles.

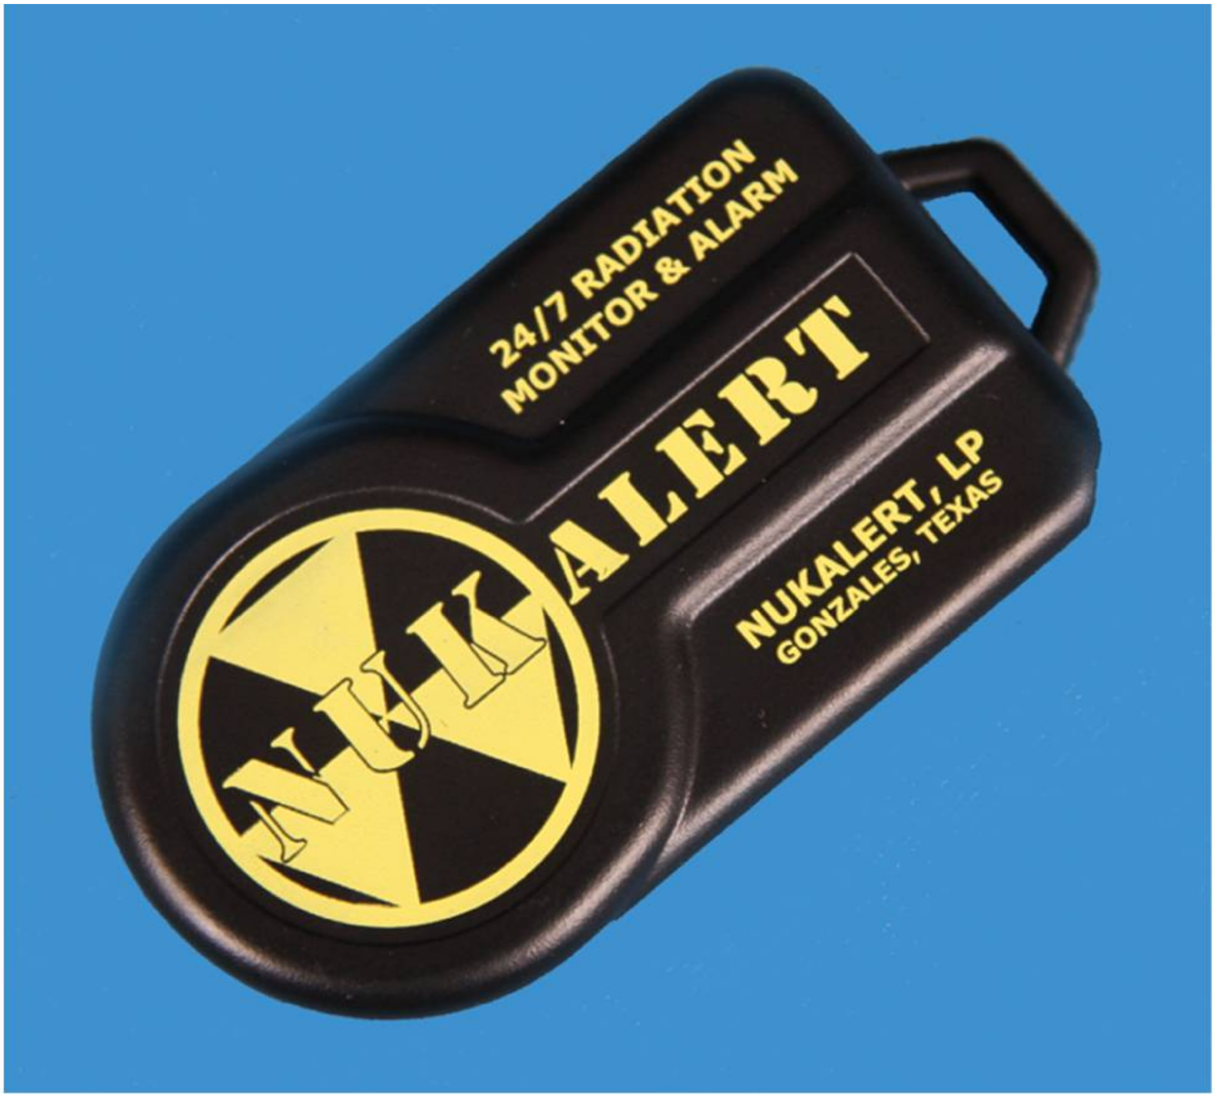

FIGURE 21-13 A radiation detection device.

NukAlert courtesy of Ki4u, Inc.

Further radiation exposure occurs during **incorporation**. Devastating individual patient toxicity develops when radioactive materials enter the body, causing ongoing internal exposure.

Clues to the diagnosis of radiation exposure may be obtained through a number of methods. A history of radiation exposure through patient report of an isolated event or widespread knowledge of a large-scale event will greatly assist in diagnosis. The military, health care facilities, emergency responders, laboratories, and industrial settings have various radiation detection devices available.

Radioactive particles may be present in a patient’s mucous membranes or body fluids and tissues. **Acute radiation syndrome** (radiation poisoning) may also be diagnosed clinically in potentially exposed people.

Emergency responders should develop a formal radiation response plan. Providers working in proximity to a radiation release need appropriate protective clothing for the situation and must use respirators to avoid inhaling contaminated material. There is little to no risk to the health care provider when caring for a patient who has been removed from the source of contamination. All exposed patients should be decontaminated before care is initiated, unless immediate life threats exist. Once patients are decontaminated, no risk exists to the health care provider from radiation.

Patient decontamination involves removing contaminated clothing and jewelry and providing copious irrigation and thorough washing of the skin with soap and water. Providers should also be checked and decontaminated if necessary. Patients who are exposed to only electromagnetic radiation do not require decontamination. Following decontamination, patients should be reassessed for the presence of persistent radiation by using a hand-held or similar device. Persistent radiation requires repeated decontamination.

Patients who experience a massive radiation exposure may die within several hours of that event. Early symptoms include nausea, vomiting, diarrhea, abdominal pain, fever, mental status changes, shock, and coma. In the first 1 to 2 days after exposure, patients may have a brief recovery period. Subsequent toxic effects include multisystem organ dysfunction, bone marrow depression, sepsis, hair loss, dermatologic injury, and eventual death.

Initial treatment focuses on removing any accessible radioactive substances in the body. Chelating agents may bind and remove certain radioactive substances. Potassium iodide can block the uptake of radioactive iodine into the thyroid gland. Water can be given to dilute tritium, and sodium bicarbonate may be used to alkalinize the urine in uranium exposures. Additional treatments depending on the patient’s presenting symptoms and are directed toward minimizing the potential for catastrophic infection.

Vehicle Decontamination

Providers must decontaminate the transport vehicle (including aircraft) after the call. This process includes the following steps:

1. Strip used linens from the stretcher immediately after use and place them in a plastic bag or the designated receptacle in the destination facility.
2. In an appropriate receptacle, discard all disposable equipment used for care of the patient that meets your state’s definition of medical waste. Most items will be considered general trash.
3. Wash all contaminated areas with soap and water. Scrub blood, vomitus, and other substances from the floors, walls, and ceilings with soap and water. Cleaning must be done first for disinfection to be effective.
4. Disinfect all nondisposable equipment used in the care of the patient. For example, the ECG leads and cables should be cleaned after each patient use as recommended by the manufacturer.
5. Clean the stretcher with an Environmental Protection Agency–registered germicidal/virucidal solution or with bleach and water at 1:100 dilution.
6. If any spillage or other contamination occurred in the transport vehicle, clean it up with the same germicidal/virucidal or bleach/water solution.
7. Clean the outside of the transport vehicle as needed.
8. Replace or repair broken or damaged equipment without delay.
9. Replace any other equipment or supplies that were used.
10. Refuel the vehicle if the fuel tank is below required reserves. Other fluid levels should be checked each time the vehicle is refueled or as your service’s standard operating procedure requires.

Restock any supplies you did not get at the receiving facility. Finally, have a written policy/procedure for cleaning each piece of equipment. Refer to the manufacturer’s recommendations as a guide.

Radiation burns appear the same way as other burns, and their management varies only by the need to decontaminate the wound of radioactive particles. In addition, for massive doses of radiation, the systemic effects of radiation exposure should be considered and treated. Wounds should be dressed with clean, dry dressings.

Flight Considerations

The importance of safety during air medical transport cannot be overstated when transporting patients following a poisoning, overdose, or toxic exposure. Affected patients pose a serious risk to the lives and health of the transport team.

As stated repeatedly throughout this chapter, patients should not be placed into any transport vehicle, but especially a helicopter or airplane, until an effective initial decontamination has been completed. Whereas ground transport vehicles can stop almost anywhere when conditions in the transport vehicle become unsafe owing to the presence of toxic substances from a contaminated patient, helicopters and airplanes require safe areas to land, which are often unavailable on short notice. In many cases, effective decontamination requires the removal of all contaminated clothing and adequate cleansing and irrigation for a particular substance before air transport can begin.

Air medical crews are also at risk from patients (or family members) with bizarre, aggressive, combative, or violent behavior. It is essential to screen patients (and family members) before transport and to use sedation and restraints as appropriate. At least one fatal air medical crash has been attributed to a patient interfering with aircraft operation. The risk from patients or family members interfering with safe aircraft or transport vehicle operation should not be underestimated.

During air medical transport, access to patients is often limited. In the confined space of an aircraft, with its environmental variables and loud noises, it may be impossible to perform an adequate patient assessment and many therapeutic interventions. Noise and vibration are likely to undermine the accuracy of patient monitoring. The low light conditions found in many aircraft make it difficult to detect skin color changes, respiratory alterations, and even subtle emesis. Air medical crews must be especially prepared to anticipate and manage changes during the flight.

Summary

The management of patients after poisoning or overdose is often a challenging, complicated endeavor. CCTPs must ensure transport team safety while optimizing the chances for patient recovery following a toxic exposure. This chapter serves only as a general overview of various toxicologic emergency situations. During actual patient care, early consultation with a toxicologist, a Poison Control Center, or a reliable toxicology reference will provide invaluable assistance. CCTPs must never lose focus on safety and the ABCs when treating or transporting patients experiencing a toxicologic emergency.

CASE STUDY

You are a member of a helicopter flight crew. You have been called to a rural facility to transport an 18-year-old man who reportedly took his mother's amitriptyline (a TCA) after his girlfriend broke up with him.

On arrival, you receive a report from the attending physician. He states that the patient took an unknown amount of amitriptyline 1 hour before his arrival at the emergency department. The patient has been in the hospital for approximately 45 minutes. He was administered 60 g of activated charcoal when he arrived. The physician reports that all of the patient's laboratory values were normal, and he recently received the patient's arterial blood gas measurements, which were as follows: pH, 7.37; $PaCO_2$, 43 mm Hg; PaO_2, 80 mm Hg; and oxygen saturation, 96%. On an ECG, the only other finding was sinus tachycardia at a rate of 118 beats/min with a prolonged QRS interval of 120 ms. The patient has a 20-gauge antecubital IV line in place.

When you obtain the patient's history from his mother, she tells you that she takes 75 mg of amitriptyline at bedtime for depression. She said she receives 2 weeks' worth of medication at a time, and she just filled her prescription. She found her son asleep on his bed with an empty pill bottle beside him. She was able to wake him up and then called 9-1-1. The mother states that her son told her that his girlfriend just broke up with him and that he just wanted to "end it all."

On your arrival at the patient's bedside, you find an 18-year-old man who appears lethargic and is currently lying on his side vomiting black charcoal. His vital signs are as follows: BP, 92/60 mm Hg; temperature, 97°F (36.1°C); pulse rate, 118 beats/min; respiratory rate, 24 breaths/min; and oxygen saturation, 92%. His Glasgow Coma Scale score is 11. The patient opens his eyes to pressure and is able to localize pain. His conversation is confused. The patient has scattered rhonchi throughout, consistent with probable aspiration. You are unable to auscultate bowel sounds, and he has diminished reflexes.

1. What are your priorities with this patient prior to transport?
2. Which other priorities would be important for the treatment of this patient?

Analysis

One of your most important priorities prior to transport is airway management. Depending on their transport vehicle, some providers might elect to rapidly transport the patient and secure the airway en route; however, this patient is already at high risk for aspiration and it would probably be more effective to manage his airway in the more controlled environment of the emergency department prior to transport. This patient needs rapid sequence intubation with both sedative and short-term paralytic medication. Long-term paralysis with a nondepolarizing paralytic should be avoided (unless your service has continuous electroencephalographic monitoring). Patients who overdose with TCAs are at high risk for seizures. Patients whose QRS interval is greater than 100 ms have up to a 34% chance of having seizures and up to a 14% chance of having a life-threatening arrhythmia. If the patient has been paralyzed with a long-term paralytic, you would be unable to tell if he is seizing.

Sedation is required to allow the patient to tolerate the ET tube. An anxiolytic agent such as lorazepam or midazolam should be used for this purpose, as these agents also protect against seizures. The typical sedative dose for midazolam is 0.025 to 0.05 mg/kg IV. If you are administering midazolam for seizures, the usual loading dose is much higher —0.1 mg/kg IV or greater. Propofol, a short-acting sedative, can be used if your service carries it or the sending agent stocks the medication. The ET tube should be secured prior to transport, and a nasogastric tube should be placed. You would also want to instill 60 g of charcoal into the nasogastric tube and then clamp it prior to transport because the patient vomited the first dose. Once BP allows it, elevating the head of the bed by 30° would further reduce the risk of continued aspiration.

Lastly, you need to secure one or two additional large-bore IV lines. Because of the anti-alpha-adrenergic effect of TCAs, this patient is at high risk for further hypotension. He will probably require aggressive fluid resuscitation to stabilize his BP during transport. If the patient remains hypotensive despite administration of fluids, you should administer vasopressors with an alpha-agonist effect (norepinephrine) to maintain an adequate BP. The additional IV lines should be started in the emergency department.

Serum alkalinization with sodium bicarbonate is important in treating patients who have taken a TCA overdose. Most Poison Control Centers recommend serum alkalinization if the QRS duration is 100 ms or greater, if the pH is less than 7.1, or if the patient is hypotensive or having arrhythmias. Alkalinization protects patients from the cardiotoxic effects of TCAs. Correction with sodium bicarbonate promotes protein binding of TCAs and improves myocardial contractility. The goal of therapy is to achieve a pH in the range of 7.5 to 7.55.

Sodium bicarbonate is initially given as a bolus of 1 to 2 mEq/kg IV. You then can begin an IV drip with 150 mEq of sodium bicarbonate per liter of 5% dextrose in water and titrate to keep the patient's pH within the goal range (1 to 3 mL/kg/h). Frequent pH determinations are needed. Obtaining this information is difficult during transport, unless you have point-of-care testing in the helicopter. If the sending institution has started this therapy, it is usually maintained during the flight and it is not titrated until the patient's pH is checked at the receiving facility. If the sending institution has not initiated this treatment, typically the bolus dose is given and the drip is started at the receiving institution.

PREP KIT

Ready for Review

- Poisons, chemicals, medications, and other toxic substances are found in dangerous quantities in homes, schools, agriculture, industry, and commercial establishments; on all modes of transportation; and naturally in the environment.
- Interventions to maintain and enhance the ABCs should not be delayed in favor of interventions specific to toxicologic emergencies (decontamination, enhanced elimination, and antidote administration), which will not become effective rapidly enough to correct immediately life-threatening problems with the ABCs.
- Primary decontamination usually occurs at the scene or outside a health care facility or transport vehicle. It is undertaken to protect rescuers and health care providers from exposure to toxic substances during patient care and transport.
- Secondary decontamination, which is directed at minimizing patient absorption of or injury from a toxic substance, poses much less risk to health care providers than does primary decontamination.
- Decontamination of a hazardous chemical should occur before an unprotected health care provider makes any contact with the material.
- If rescuers or health care providers do not use the correct PPE before initial patient contact, it may be too late for the equipment to provide adequate protection.
- CCTPs may encounter hazardous situations during anticipated patient transports between health care facilities, while responding to an emergency in the community, or by happening on a vehicular crash.
- Patients may sometimes exhibit violent, bizarre, or aggressive behavior, such that medical or physical restraints may be

necessary before effective assessment or treatment can begin.

- Potentially suicidal, combative, aggressive, violent, intoxicated, and confused patients should be restrained, using physical restraints or medical sedation, before transport.
- All patients should be evaluated for the presence of weapons before transport.
- Once the safety concerns have been addressed, maintaining or establishing a patent airway is the top priority in the management of a patient with a toxic exposure.
- A previously patent airway may become compromised during patient transport owing to alteration in the patient’s mental status or seizure activity, evolving structural abnormalities from trauma or increasing edema, or obstructions from emesis, secretions, or a foreign body that becomes displaced during the transport.
- Patients who received activated charcoal or syrup of ipecac have an unusual risk of subsequent airway compromise.
- If any doubt arises about the patient’s ability to maintain the airway during transport, the airway should be secured with an ET tube.
- Breathing is second only to the airway in importance during patient assessment. Without effective oxygenation and ventilation, tissue hypoxia, acidosis, and cell death will occur.
- Patients with physiologic stress, acidosis, hypermetabolic states (such as occur in pediatric patients), or exposure to many toxic substances require greater oxygenation and ventilation than would usually be required.
- Conventional ventilator settings are often inadequate to meet a patient’s needs following a poisoning or overdose.
- Cyanosis, fatigue, and dyspnea indicate that a patient’s respiratory status may be compromised.
- Lung auscultation findings of wheezing, pulmonary edema, and decreased, absent, or coarse breath sounds indicate the patient has an unstable respiratory status.

- Oxygen saturation, blood gas analysis, and $ETCO_2$ provide valuable information about the adequacy of oxygenation and ventilation; ongoing monitoring of respiration focuses on changes in breath sounds, patient appearance, and cardiovascular function (as shown by an ECG and assessment of perfusion).
- Evaluation of a patient’s circulation requires assessment of end-organ tissue perfusion and overall cardiovascular functioning.
- During the evolution of a toxic exposure, a patient’s circulatory status may decline because of the following factors:
  - Direct exposure to cardiotoxic or vasoactive substances
  - Fluid volume loss or redistribution
  - Electrolyte disturbance
  - Airway or respiratory compromise with secondary cardiac dysfunction
  - Manifestations of preexisting cardiovascular disease
  - Altered oxygen-carrying capacity
- Toxic exposures may cause alterations in vascular tone, kidney function, and electrolyte concentration, thereby disrupting fluid balance.
- The patient, family, and bystander interviews may provide valuable clues about the nature and severity of a toxic exposure, including information about prodromal symptoms and preexisting medical conditions.
- Transport teams must balance the usefulness of a complete head-to-toe physical examination with concerns for patient thermoregulation, privacy, patient access in confined transport vehicles, and the patient’s clinical needs.
- Vascular access or intraosseous access sufficient for administering emergency medications and fluids should be established in any patient exposed to a potentially harmful substance.

- Every patient must receive adequate sedation and analgesia while medically paralyzed and should be prophylactically medicated against seizures.
- Patients with increased drug tolerance or a hypermetabolic state require significantly more sedation and analgesia while chemically paralyzed.
- Nonintubated patients require anxiolysis and analgesia following many toxicologic exposures.
- Psychiatric and other at-risk patients may require sedative medications to facilitate patient care and promote patient comfort.
- Hemodynamic and respiratory alterations (eg, tachycardia, bradycardia, hypertension or hypotension, and hyperthermia or hypothermia) may occur as a result of direct action on organs and tissues or through effects on the CNS.
- Advances in point-of-care testing technology allow CCTPs to measure blood chemistry values, arterial or venous blood gases, and other assorted values during transport and obtain results almost immediately.
- Exposure to certain classes of chemicals and medications produces a readily identifiable pattern of clinical signs and symptoms (toxidrome), which aids in diagnosis when the exact nature of the exposure is unclear.
- Some patients may experience life-threatening reactions even when medications are taken at therapeutic doses.
- Anticholinergic syndrome occurs following excessive exposure to medications such as antihistamines, atropine, and benztropine, resulting in muscarinic receptor blockade at the CNS and various other organs.
- Cholinergic syndrome (cholinesterase inhibitor toxicity) occurs following exposure to organophosphate and carbamate insecticides or to certain chemical nerve agents. Cholinesterase inhibitors may affect nicotinic receptors, muscarinic receptors, or both, and alter the function of the neurotransmitter acetylcholine.

- Opioid syndrome commonly develops following illicit use or abuse of opioids in the community or as an adverse consequence of a therapeutic error or accidental ingestion of opioids (eg, morphine, heroin, and fentanyl).
- The administration of an opioid antagonist (naloxone) as a treatment for opioid syndrome may precipitate severe, violent withdrawal symptoms. Many opioids also exert effects much longer than the duration of opioid antagonists, meaning that life-threatening symptoms may return after administration of therapy.
- Sympathomimetic syndrome involves overstimulation of the adrenergic nervous system, resulting in tachycardia, hypertension, agitation, seizures, hyperthermia, dilated pupils, and diaphoresis.
- Malignant hyperthermia occurs following the administration of succinylcholine or certain inhaled anesthetic agents to genetically susceptible patients; it is characterized by muscle spasms, profound muscle rigidity, acidosis, hypercarbia, hyperthermia, tachycardia, tachypnea, myoglobinuria, rhabdomyolysis, and hyperkalemia.
- Neuroleptic malignant syndrome is a potentially fatal reaction to antipsychotic medications; it is characterized by hyperthermia, profound muscle rigidity, metabolic acidosis, autonomic dysfunction, confusion, and, in severe cases, renal failure, respiratory failure, arrhythmias, and cardiovascular collapse.
- Serotonin syndrome is an unusual response to serotonin-altering medications that cause hyperserotoninergic symptoms (eg, irritability, muscle rigidity, clonus, myoclonus, hyperthermia, diaphoresis, headaches, seizures, coma, tachycardia, and hallucinations).
- Patient decontamination following exposure to a toxic substance is directed toward minimizing the quantity of the substance absorbed by the patient and the extent of any local damage. Decontamination may be as simple as providing the patient with fresh air or as complicated as whole-bowel irrigation.

- Chemical warfare nerve agents can cause systemic toxic effects from dermal absorption; other caustic chemical warfare agents cause severe local reactions or burns when they come in contact with skin.
- Flushing with water or saline (if the chemical is not water-reactive) is the recommended approach for removal of chemical agents from the patient's skin or eyes.
- Methods for gastrointestinal decontamination include activated charcoal administration, gastric lavage and emptying, and whole-bowel irrigation; however, gastric lavage and whole-bowel irrigation are not done in the transport environment.
- Enhanced elimination methods such as dialysis and urinary alkalinization may be considered if the patient is exposed to lethal quantities of a toxic substance, the ordinary route of elimination from the body is impaired by the overdose or other pathology, or a preexisting medical condition suggests that the patient will not tolerate the adverse effects of the poisoning.
- Acetaminophen toxicity, which can result in liver failure in severe cases, is treated with initial gastrointestinal decontamination with activated charcoal, followed by oral or IV acetylcysteine (Mucomyst, Acetadote).
- In the field, treatment of an amphetamine overdose—which presents with classic sympathomimetic symptoms—is largely supportive, but may also include sedation with benzodiazepines.
- The majority of patients who experience benzodiazepine overdose require only conservative management and careful observation.
- Glucagon is the initial treatment of choice for a beta blocker overdose. In large ingestions, however, multiple therapies are required.
- One tablet of a calcium channel blocker is often enough to cause serious toxicity or death in a small child. Intravenous calcium is the initial antidote to an overdose of a calcium channel blocker. However, in large ingestions, multiple therapies are required.

- Symptoms of chronic cardiac glycoside toxicity are often vague, frequently leading to misdiagnosis.
- There is no antidote for cocaine toxicity; the treatment for overdose of this illicit drug is supportive, including sedation, and is based on the patient's clinical presentation.
- Patients who experience an opioid overdose can have profound CNS and respiratory depression. Naloxone—which may be administered intravenously, intramuscularly, subcutaneously, via ET tube, nebulized, or intranasally—will reverse the opioid effects and often reestablish a patent airway and spontaneous breathing.
- Any new patient report of tinnitus, dizziness, or deafness should prompt an evaluation for possible salicylate poisoning. There is no antidote for salicylate poisoning, but this condition is a candidate for enhanced elimination with urine alkalinization and hemodialysis. Intubation without adequate ventilation may acutely worsen the toxicity.
- In selective serotonin reuptake inhibitor (SSRI) overdose situations accompanied by serotonin syndrome, the treatment is supportive and based on the patient's presenting symptoms.
- Ethylene glycol and methanol can cause profound, lethal metabolic acidosis following ingestion of even very small quantities of these chemicals. Two antidotes are available for the treatment of methanol and ethylene glycol poisoning: ethanol and fomepizole.
- Any patient admitted to a health care facility for an intentional overdose should be screened for the presence of tricyclic antidepressants (TCAs) with an ECG and given aggressive supportive treatment following a TCA overdose.
- The potential for rescuer exposure is high when the incident involves acetylcholinesterase inhibitors, such as during unintentional contact with certain pesticides or as part of a chemical weapon release. Rescuers or health care providers using the appropriate PPE should promptly initiate skin and eye decontamination.

- The brain and heart are the primary sites of carbon monoxide (CO) toxicity owing to their large oxygen requirements. If CO exposure is suspected, aggressive treatment with high-dose oxygen should be started before laboratory results are obtained.
- Exposure to caustic agents can occur through inhalation, ingestion, dermal exposure, or eye exposure; ingestion of these agents has the potential to cause devastating injury.
- Chlorine, ammonia, and asphyxiate gases have the potential to displace oxygen in a patient’s lungs; damage or irritate the mouth, nose, and airway; and otherwise disrupt effective respiration. Symptomatic patients may require supplemental oxygen, bronchodilator medications, humidified oxygen or air, or assisted ventilation in severe exposures.
- Although cyanide poisoning can be confirmed with serum cyanide and thiocyanate levels, these measurements are often not readily available. Patients with such toxicity will experience a multitude of neurologic, cardiovascular, and respiratory symptoms. Any exposure to cyanide should be considered potentially lethal. Patients should be treated with hydroxocobalamin (Cyanokit) or sodium nitrite and sodium thiosulfate (Nithiodote).
- Hydrocarbons can cause toxicity directly in the lungs or may be absorbed across the lungs or GI tract and result in systemic toxicity.
- Hydrocarbons such as gasoline, kerosene, and petroleum may pose a risk of chemical pneumonitis following their aspiration. The care of patients who have toxic exposures to these substances is largely supportive and includes oxygen, bronchodilators, and steroids for wheezing and intubation for hypoxia and CNS depression.
- Hydrofluoric acid is a potent caustic substance that can cause devastating local and systemic toxicity from exposure to even a small amount of concentrated liquid. The treatment for hydrogen fluoride poisoning includes administering a calcium- or magnesium-

containing substance such as milk, antacids, magnesium citrate, or magnesium hydroxide.

- A variety of substances can cause serious illness or death in very small quantities, especially in children. The top three culprits in such pediatric poisonings are calcium channel blockers, beta blockers, and TCAs.
- At a hazardous materials incident, CCTPs without specialized training or equipment should remain well outside the “hot” and “warm” zones, where provider exposure to toxic substances is possible.
- Poison Control Centers and CHEMTREC may provide invaluable assistance to health care providers at incidents involving hazardous materials.
- The main objective of CCTPs at hazmat scenes is to assess and ensure personnel safety during patient care and transportation; only when these concerns are addressed can patient assessment and treatment begin.
- Once adequate patient decontamination has been performed and other safety concerns have been addressed, patients involved in hazmat incidents should be transported to the closest appropriate health care facility.
- CCTPs should carefully monitor for the following situations during patient transport:
  - Deterioration of the patient’s clinical condition as the toxic exposure evolves
  - Signs of inadequate decontamination
  - Any interventions appropriate for the patient’s clinical situation, within the ability of the transport team, that have not been already performed
- Radiation release may occur in health care, industrial, or laboratory settings; during transportation and disposal of radioactive materials; and following a military or terrorist event. Patients may die within several hours of a massive radiation

exposure. The use of a radiation detection device will help identify which patients are contaminated with radioactive particles.

- Radiation burns appear the same way as other burns; their management varies only by the need to decontaminate the wound of any radioactive particles.
- In the flight environment, effective initial decontamination before takeoff is extremely important. Other flight considerations for critical toxicologic emergencies include thoroughly screening patients and family members to prevent violence and behavioral problems during flight and anticipating changes in the patient's condition that may be difficult to detect during flight.

Vital Vocabulary

activated charcoal A carbon-based liquid with an incredible adsorptive ability that is typically administered orally or via nasogastric or orogastric tube to decrease the available quantity of a toxic substance.

acute radiation syndrome Radiation poisoning.

adsorption The process of attracting molecules of a substance to the surface of that substance.

anticholinergic syndrome A syndrome that occurs following excessive exposure to medications such as antihistamines, atropine, and benztropine (Cogentin), or other substances such as jimson weed, resulting in muscarinic receptor blockade at the CNS and various other organs; characterized by tachycardia, hyperthermia, dilated pupils, warm (or hot) dry skin, ileus, delirium, seizures, hallucinations, and urinary retention.

anxiolysis The reduction of anxiety by the administration of an antianxiety agent.

body packers People who swallow carefully prepared packages of illicit substances for smuggling purposes.

body stuffers People who hastily swallow poorly packaged illicit substances (often to avoid impending arrest).

cholinergic syndrome Cholinesterase inhibitor toxicity.

cocaine washout syndrome Profound exhaustion with the ability to regain normal mental status and orientation when aroused; commonly seen with heavy cocaine users.

contamination A state in which a certain substance, such as blood, infectious material, or a toxic substance, is present on an item or surface. In the case of radiation, it is important to distinguish between contamination and irradiation.

DUMBELS Mnemonic for symptoms of anticholinesterase inhibitor toxicity: Diaphoresis/diarrhea, Urination, Miosis, Bradycardia/bronchospasm/bronchorrhea, Emesis, Lacrimation, and Salivation.

enhanced elimination A process that replaces or augments the body's normal method of eliminating, modifying, or breaking down toxic substances.

gluconeogenesis Glucose formation.

glycogenolysis The breakdown of glycogen to glucose.

hemoperfusion A treatment in which a patient's blood is filtered outside the body through a substance that removes toxic substances from it; a method of removing toxic substances from the blood.

hepatotoxicity Damage to the liver.

incorporation In the radiation context, a process in which radioactive materials enter the body during radiation exposure, causing ongoing internal exposure and creating devastating individual patient toxicity.

inotropic Affecting the contractility of muscle tissue, especially cardiac muscle.

irradiation Exposure to radiation. It is important to distinguish between irradiation and contamination because health care providers and emergency responders are not placed at any risk by patients who have been irradiated but are not contaminated.

malignant hyperthermia A condition that may occur after administration of certain inhaled anesthetics; characterized by muscle spasms, rigidity, acidosis, hypercarbia, hyperthermia, tachycardia, tachypnea, myoglobinuria, rhabdomyolysis, and hyperkalemia.

neuroleptic malignant syndrome (NMS) A potentially fatal reaction to antipsychotic and neuroleptic medications; characterized by patient hyperthermia, profound muscle rigidity, autonomic dysfunction, metabolic acidosis, and confusion.

opioids The class of chemicals that includes naturally derived opiates and newer synthetic medications with the same properties.

opioid syndrome Toxicity that develops following illicit use and abuse of opioids or as an adverse consequence of a therapeutic error or accidental ingestion of opioids and characterized by CNS and respiratory depression.

phosphodiesterase An enzyme that helps break phosphodiester bonds, creating smaller nucleotides.

point-of-care testing Laboratory testing that is performed at the point of care—for example, at the bedside—so that results can be quickly obtained and considered while decisions are being made about patient care.

primary decontamination A form of decontamination that usually occurs at a scene or outside a health care facility or transport vehicle; intended to protect rescuers and health care providers from exposure to a toxic substance during patient care and transport.

prodromal Referring to the early signs and symptoms that occur before a disease or condition, such as a toxic exposure, fully appears—for example, dizziness before fainting.

pulse CO-oximetry A noninvasive screening and monitoring method for methemoglobinemia and carbon monoxide exposure.

rhabdomyolysis The destruction of muscle tissue.

secondary decontamination A form of decontamination directed at minimizing patient absorption or injury from a toxic substance; it occurs after initial decontamination has occurred outside a health care facility or transport vehicle.

sedative-hypnotic syndrome A syndrome characterized by lethargy, sedation, hypoventilation, apnea, bradycardia, and hypotension that occurs following exposure to any medication or chemical that can cause central nervous system sedation, lethargy, or coma.

serotonin syndrome An unusual response to serotonin-altering medications causing hyperserotoninergic symptoms.

SLUDGEM Acronym for symptoms of anticholinesterase inhibitor toxicity: Salivation, Lacrimation, Urination, Diarrhea, Gastroenteritis, Emesis, and Miosis.

stimulant washout syndrome Excessive sleep, hunger, and depression as a result of excessive amphetamine use.

sympathomimetic syndrome A syndrome that involves overstimulation of the adrenergic nervous system, resulting in tachycardia, hypertension, agitation, seizures, hyperthermia, dilated pupils, and diaphoresis.

toxidrome A group of symptoms, or syndrome, associated with toxicity of a given substance.

whole-bowel irrigation (WBI) A gastric decontamination method that involves the patient drinking or receiving via a nasogastric tube large quantities of a nonabsorbable, electrolyte-balanced liquid that propels stomach and intestinal contents through the digestive system.

CHAPTER 22

Obstetric and Gynecologic Emergencies

Kathleen Kerrigan, MD
Adrianne Wurzl, DO

OBJECTIVES

After completing this chapter, you will be able to:

1. Discuss the anatomy of the female reproductive system (p 1186).
2. Recognize the physiologic changes that occur during pregnancy (p 1188).
3. Describe the changes that occur in the cardiovascular, respiratory, gastrointestinal, renal, and endocrine systems during pregnancy (pp 1188–1191).
4. Discuss dermatologic changes that occur during pregnancy (p 1191).
5. Discuss special areas of concern when performing a critical care transport of a pregnant patient (p 1191).
6. Describe the management of the pregnant patient who is in cardiac arrest (p 1192).
7. Discuss potential maternal cardiovascular complications exacerbated or induced by pregnancy (p 1192).
8. Discuss fetal oxygenation and heart rate, including conditions associated with fetal distress during labor (p 1193).
9. Discuss how to assess a fetus during a critical care transport (p 1193).
10. Describe several methods of fetal monitoring during critical care transport of a pregnant patient, including electronic fetal monitoring (p 1195).
11. Explain how to use a Doppler device (p 1197).
12. Describe the complications of pregnancy, including early pregnancy loss, ectopic pregnancy, and causes of bleeding (pp 1202–1203).
13. Discuss the signs and symptoms and treatment of abruptio placentae, placenta previa, and uterine rupture (pp 1203–1206).
14. Discuss medical conditions that can exist during pregnancy, including hypertension complicating pregnancy, preeclampsia, eclampsia, and HELLP syndrome (pp 1206–1209).

15. Explain how to manage medical conditions that can exist during pregnancy, including hypertension complicating pregnancy, preeclampsia, eclampsia, and HELLP syndrome, during critical care transport (pp 1206–1209).
16. Explain the concerns regarding preterm labor and premature delivery (p 1209).
17. Discuss the use of tocolytic agents to interrupt labor (p 1211).
18. Recognize fetal malpresentations of delivery, including frank breech, complete breech, incomplete breech, footling breech, and umbilical cord prolapse (pp 1212–1214).
19. Discuss how to manage fetal malpresentations during a critical care transport (p 1212).
20. Describe shoulder dystocia (p 1215).
21. Explain how to manage shoulder dystocia during a critical care transport (p 1215).
22. Discuss multiple-birth deliveries (p 1216).
23. Explain how to manage multiple-birth deliveries during a critical care transport (p 1216).
24. Discuss postpartum care of the mother and infant during a critical care transport (p 1217).
25. Describe potential postpartum complications and their management during critical care transport, including postpartum hemorrhage and amniotic fluid embolism (pp 1217–1218).
26. Recognize gynecologic issues and emergencies, including pelvic inflammatory disease, toxic shock syndrome, ovarian cysts, pathologic cysts, ovarian torsion, and gynecologic trauma (pp 1219–1222).
27. Discuss how to manage gynecologic emergencies, including pelvic inflammatory disease, toxic shock syndrome, ovarian cysts, pathologic cysts, ovarian torsion, and gynecologic trauma, during critical care transport (pp 1219–1222).

Introduction

Management of the pregnant patient can challenge the critical care transport professional (CCTP). In such a scenario, the CCTP must take into account the competing concerns of the woman and the fetus, the physiologic changes induced by pregnancy, and the presence of potentially life-threatening pathologic conditions. This chapter provides an overview of the physiologic changes in pregnancy and describes specific emergency conditions associated with pregnancy, childbirth, and postpartum care. Understanding of the anatomic and physiologic changes that occur during pregnancy is essential to provide effective care to obstetric patients.

CONTROVERSIES

A common concern when faced with a critically ill or injured pregnant woman is whether the mother or the fetus takes priority. In all cases, the priority is resuscitation and stabilization of the mother. The key to a viable fetus, even when a decision is made to expedite delivery, is restoration of adequate perfusion in the mother.

Anatomy and Physiology of the Female Reproductive System

Within the female reproductive system, the 28-day menstrual cycle is regulated by a series of hormonal secretions. These hormones prepare the uterus for implantation of a fertilized egg and the start of pregnancy. In the absence of pregnancy, the uterine wall sheds its inner lining, known as the **endometrium**. The mucosal tissues and blood are discharged through the vagina, in a process known as menstruation. Menstruation lasts approximately 3 to 7 days.

FIGURE 22-1 depicts the menstrual cycle. At the beginning of the menstrual cycle, a rise in the levels of follicle-stimulating hormone (FSH) triggers the start of the preovulatory phase, also known as the follicular phase. During the next 7 to 8 days, the uterine wall begins to swell, or proliferate, and the process of maturity begins with follicle stimulation in the ovaries. FSH stimulates the creation of an oocyte in the ovary. As the oocyte begins to mature, the ovary secretes estrogen, which causes the endometrium to swell with blood. As the follicle matures, the increased levels of estrogen cause the anterior pituitary to secrete luteinizing hormone (LH). Introduction of this hormone stimulates the release of the oocyte—called an ovum now that it is mature—from the ovaries and the start of ovulation. For the next 24 to 48 hours, as the newly formed ovum travels down the fallopian tube to the uterus, the woman’s fertility is at its peak. A hard shell known as the corpus luteum, which begins to secrete more estrogen, testosterone, and progesterone, is left behind in the ovary. As progesterone levels rise over the next 14 days, the endometrium continues to swell and provides a soft shelter for the egg. If conception does not occur, the unfertilized ovum travels into the uterus. Progesterone levels drop off as the corpus luteum begins to dissolve in the ovary and menstruation begins, ending the cycle.

Description

Conception and Gestation

If fertilization has occurred, the egg—known as the zygote—implants in the endometrium. Blastocytes inside the zygote secrete human chorionic gonadotropin (hCG), which extends the life of the corpus luteum. The placenta, which is attached to the wall of the uterus, supplies the fetus with oxygen and vital nutrients and removes waste products such as carbon dioxide. In addition, the placenta continues to secrete the progesterone needed to maintain a swollen endometrium and continue the pregnancy. The placenta and the fetus are connected by the umbilical cord, which contains two arteries and one vein that carry the blood of the fetus to and from the placenta **FIGURE 22-2**.

Description

The placenta is an ephemeral, or transitory, organ that is formed early by the implantation of the zygote into the endometrium. The placenta grows with the fetus; it contains a thin membrane that separates maternal and fetal blood from coming into contact with each other. Nutrients, oxygen, and carbon dioxide diffuse across this membrane to nourish the placenta. It is important to understand that maternal blood is never shared with fetal blood; a fetal barrier prevents maternal blood from entering the fetal circulation, although substances from the maternal blood, such as nutrients and some medications, do pass through this barrier. For this reason, CCTPs need to be aware of the medications that can be given to a pregnant patient as well as those that should be avoided. For more information on medication considerations relating to the pregnant patient, see Chapter 8, *Critical Care Pharmacology*.

Early in pregnancy, the uterus is contained entirely within the protective ring of the pelvis. By the 12th week of **gestation**, the enlarged uterus begins to rise out of the pelvis and into the abdomen. By 20 weeks' gestation, the uterus is at the umbilicus; by 34 to 36 weeks' gestation, it reaches the costal margin. This expansion, from approximately 2 to 39 ounces (50 to 1,100 g) at **term** (39 to 40 weeks' gestation), is due to marked stretching and hypertrophy of existing muscle cells, rather than generation of new cells.

As the uterus enlarges, its walls become thinner and more fragile. The bowel is pushed cephalad and is somewhat more protected from blunt injury to the abdomen. However, as the uterus rises out of the pelvis, it loses the bony protection provided by the pelvis and becomes more vulnerable to trauma. Also, as the fetus grows, the relative proportion of amniotic fluid to fetal size decreases, making the fetus more vulnerable to trauma.

During the last 2 weeks of the pregnancy, the fetal head begins to drop lower into the pelvis in preparation for delivery. As a result, the fundal height, or distance from the pelvic ring to the top of the uterus, decreases by about 1 inch (2 cm).

To measure the fundal height **FIGURE 22-3**, place a tape measure from the pubic symphysis to the top of the fundus. MacDonald's rule states that the length in centimeters is proportionate to the number of weeks of gestation. For example, a woman who is 15 weeks pregnant would have a fundal height of about 6 inches (15 cm), give or take 0.5 to 1 inch (1 to 3 cm). This method is valid from the 12th week until the 38th week of gestation.

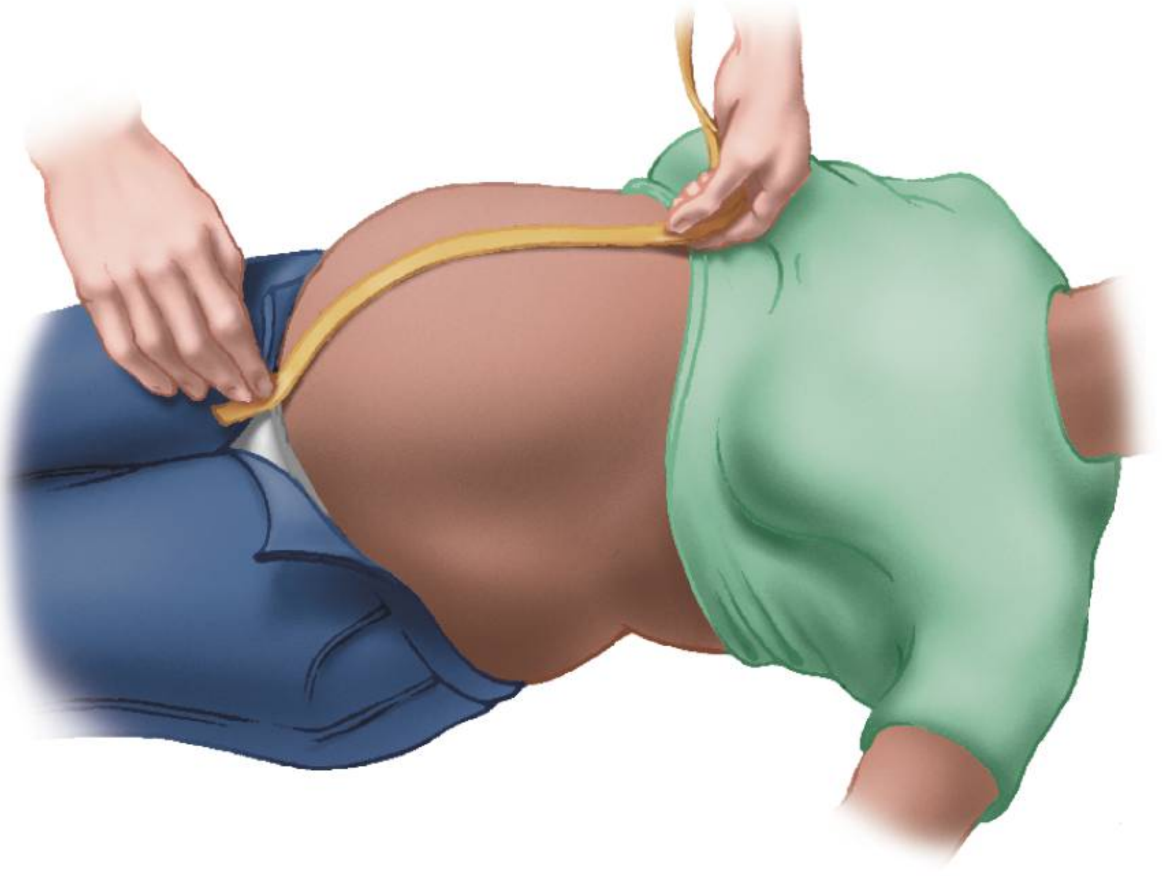

FIGURE 22-3 Measuring fundal height.

Physiologic Changes During Pregnancy

Pregnancy alters the normal physiology of females, affecting nearly every organ system. These changes may mask well-recognized signs or symptoms of disease, or normal changes may even masquerade as pathologic conditions. A functional knowledge of these alterations is essential to manage a pregnant patient effectively.

Cardiovascular System

Changes to the heart function itself may create significant challenges in the CCTP's assessment and treatment of pregnant patients. Maternal cardiac output begins to increase by week 5 and remains elevated throughout the duration of pregnancy. During the first 10 weeks of pregnancy, the cardiac output increases 20% to 30%, or 1 to 1.5 L/min, and by gestational term it could be as much as 43% higher than baseline. This increase in the cardiac output is primarily due to an increase in plasma volume, a decrease in vascular resistance, and an increase in heart rate by approximately 10 beats/min. This change in hemodynamics allows for increased blood flow to the uterus. The increased baseline pulse rate must be considered when the CCTP is interpreting a pregnant woman's tachycardia in response to hypovolemia.

Cardiac arrhythmias are also quite common in pregnancy. A common finding is sinus tachycardia, with the average maternal heart rate being 60 to 104 beats/min by the third trimester. Atrial fibrillation, atrial flutter, supraventricular tachycardia (SVT), premature atrial contractions (PACs), and premature ventricular contractions (PVCs) all have an increased prevalence during pregnancy, as do ventricular tachycardia and heart failure.

Another consideration regarding the pregnant patient's heart function is the positioning of the heart. Elevation of the diaphragm during pregnancy causes a leftward and upward shift of the heart, which can present on electrocardiograms as left axis deviation, and even Q waves in leads II, III, and aVF or inverted T waves in III and V_1–V_3.

Blood Pressure

By weeks 6 to 8, blood pressure (BP) begins to drop as a result of the ongoing release of progesterone, which relaxes the walls of the blood vessels, causing a decrease in systemic vascular resistance. BP reaches its lowest point in the second trimester, decreasing by 5 to 10 mm Hg systolic and 10 to 15 mm Hg diastolic. At term, BP returns to near prepregnancy levels. CCTPs need to be mindful that patients may present with slightly lower BP levels than baseline when they are trying to distinguish physiologic versus pathologic hypotension in the pregnant patient.

Body positioning in the third trimester may significantly affect BP and cardiac output. When the patient is lying supine, the uterus may compress the inferior vena cava, reducing venous return from the lower extremities and causing hypotension. This phenomenon is referred to as **supine hypotensive syndrome**. Displacement of the gravid uterus off of the vena cava by manual manipulation or by placement of the patient in the left lateral position will relieve this obstruction and, in turn, restore BP.

For patients secured to a long backboard, it is important to tilt the backboard to the left to relieve the pressure on the inferior vena cava. This positioning is accomplished by placing blankets or towels under the right side of the backboard **FIGURE 22-4**. Note that these materials are placed under the backboard, not directly under the patient.

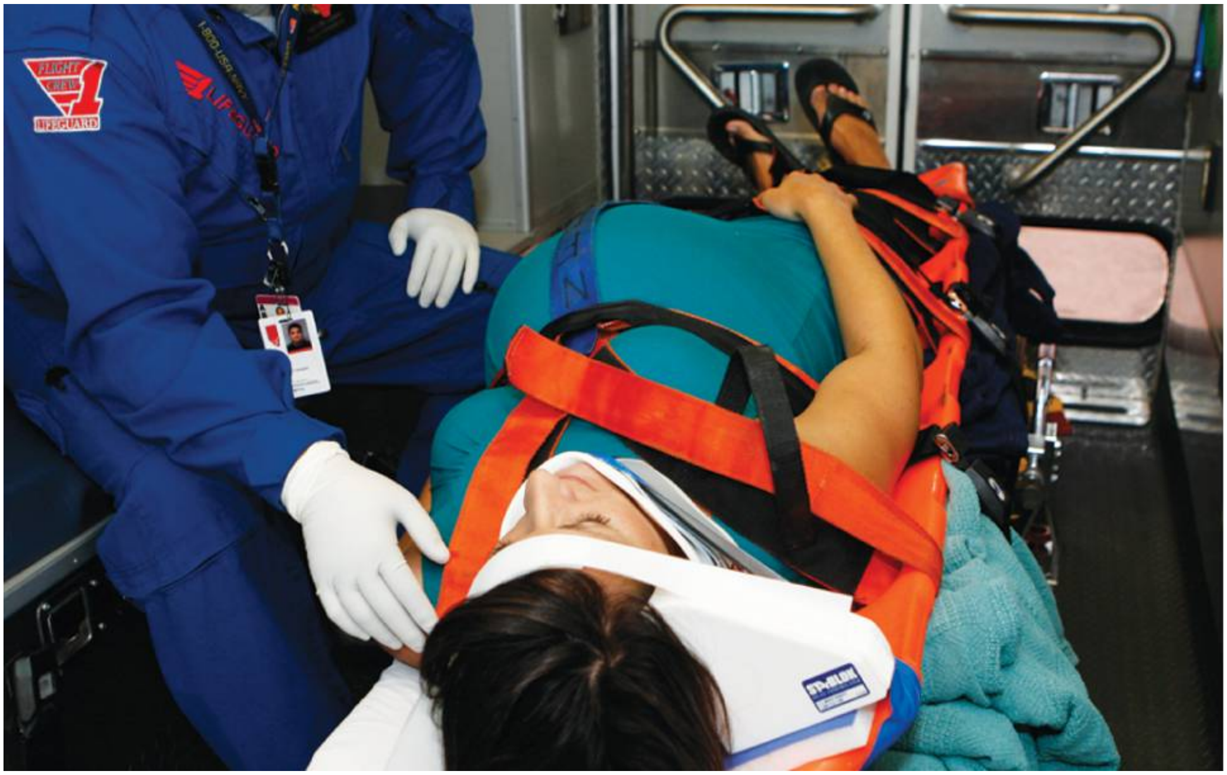

FIGURE 22-4 Place pregnant patients with spinal injuries on a backboard with blankets and towels under the right side of the backboard to tilt it toward the left and relieve pressure on the inferior vena cava.

© Jones & Bartlett Learning.

Venous Pressure

The peripheral venous pressure in the lower extremities also increases progressively during the later stages of the pregnancy. The compression of the inferior vena cava and pelvic veins by the uterus causes this increased pressure. As a result, more bleeding than expected may occur from minor wounds to the lower extremities. Increased venous pressure can also increase the patient's risk of leg edema, hemorrhoids, varicose veins, and deep venous thrombosis.

TABLE 22-1 summarizes cardiovascular system changes during pregnancy.

TABLE 22-1 **Cardiovascular Changes in Normal Pregnancy**

	Nonpregnant Patient	**Pregnant Patient**
Cardiac output	<5,000 mL/min	Up to 7,000 mL by third trimester (30% to 50% increase)
Stroke volume	65 mL	85 mL
Pulse rate	80 beats/min	10% to 20% increase
Red blood cell mass	5 million mm^3	Up to 40% increase
Systemic vascular resistance	1,500 dyne-sec/cm^{-5}	25% decrease
Mean arterial pressure	85 mm Hg	Gradual decrease until 16 to 20 weeks, then return to normal
Systolic blood pressure	120 mm Hg	120 mm Hg
Diastolic blood pressure	70 mm Hg	80 mm Hg

Data from Hall ME, George EM, Granger JP. The heart during pregnancy. *Rev Esp Cardiol*. 2011;64(11):1045-1050; Sanhavi M, Rutherford JD. Cardiovascular physiology of pregnancy. *Circulation*. 2014;130(12):1003-1008.

Blood Volume and Composition

One of the most significant changes in pregnancy is the marked increase in total plasma volume. Circulating blood volume expands by an average of 40% to 45%. This greater volume provides adequate blood supply to the fetus and compensates for impaired venous return to the maternal heart and blood loss during labor. Hemoglobin and hematocrit concentrations do not, however, increase by the same amount. The increase in plasma volume is greater than the increase in the level of hemoglobin, causing dilutional anemia. The hematocrit value decreases, reaching its lowest point between 32 and 34 weeks' gestation. This point is referred to as the physiologic anemia of pregnancy. The Centers for Disease Control and Prevention (CDC) defines anemia during pregnancy as a hemoglobin level less than 11.0 g/dL in the first and third trimesters, and less than 10.5 g/dL in the second trimester. Platelet counts, however, remain stable throughout pregnancy.

The leukocyte count is generally elevated during pregnancy and may reach 25,000/μL during labor. However, beginning in the second trimester, leukocyte function is usually depressed, which can leave the pregnant patient more vulnerable to infection.

Other changes in blood components during pregnancy include an increase in clotting factors. Increased coagulation factors decrease the **prothrombin time (PT)** and **partial thromboplastin time (PTT)**. Fibrinogen levels increase dramatically during pregnancy, nearly doubling by delivery. These changes predispose pregnant patients to clotting and deep vein thrombosis in the lower extremities and pulmonary embolus.

Given their larger blood volume, pregnant patients with active bleeding may experience a significant blood loss before they exhibit clinical signs and symptoms of hypovolemia, including changes in vital signs. While external bleeding may be obvious on physical exam, internal bleeding may be masked by relatively unchanged vital signs. CCTPs must be aware that these patients, especially those who have sustained known blunt trauma to the abdomen, may have significant internal bleeding with normal vital signs in the beginning but then quickly decompensate once a significant blood volume is lost. Thus, pregnant patients with blunt trauma must be considered to have internal bleeding even when they are hemodynamically stable.

Respiratory System

The respiratory system undergoes significant changes during pregnancy. The diaphragm elevates approximately 4 cm by term. Chest diameter increases, though overall the functional reserve capacity decreases. Minute ventilation increases due to an increase in tidal volume, likely secondary to increased levels of progesterone. The increased ventilation leads to a lower P_{CO_2} (partial pressure of carbon dioxide) level of approximately 30 mm Hg (normal is 40 mm

Hg) and respiratory alkalosis. The body compensates for the increase in pH by creating a state of metabolic acidosis, resulting in only a mild change in the overall pH to a slightly more alkalotic state, with the average pH ranging from 7.40 to 7.47. Respiratory rate stays below 20 breaths/min, and a rate higher than 20 breaths/min should be considered abnormal.

The demand for increased oxygen created by the growing fetus results in a significantly reduced oxygen reserve for the mother. In turn, desaturation occurs more quickly in pregnant patients than in nonpregnant patients. Using the accessory muscles is also difficult for pregnant patients in respiratory distress because the diaphragm is displaced and the abdominal muscles are weakened, resulting in ineffective tripoding. CCTPs must be aware that pregnant patients in respiratory arrest are likely to become hypoxic faster than nonpregnant patients. Early oxygenation to ensure a saturation level of 92% or greater and aggressive airway management with intubation should be primary considerations. Laryngeal edema should be expected, with an average Mallampati score of 3 (discussed in detail in Chapter 6, *Respiratory Emergencies and Airway Management*). Consider use of alternative airways if you are unable to intubate a pregnant patient; use of a bag-mask device alone will increase her already high risk of aspiration.

Gastrointestinal System

The gastrointestinal system undergoes positional changes and overall relaxation during pregnancy. The uterus displaces the stomach and intestines cephalad, increasing the risk of nausea and vomiting. Gastric emptying is delayed and gastroesophageal sphincter tone is reduced, leading to gastroesophageal reflux and further nausea and vomiting. Increased nausea and vomiting can place patients at higher risk of dehydration. Administration of intravenous (IV) fluids and oxygen and patient positioning (position of comfort or on the left side) can help lessen these effects during transport.

During labor, gastric emptying time may increase further, increasing the likelihood of regurgitation and aspiration. The risk is further increased if the patient has an altered level of consciousness or if analgesics are administered. Consequently, CCTPs must consider intubation early in the pregnant patient because of the higher probability of aspiration.

Gastrointestinal changes also require consideration in pregnant trauma patients. Given the displacement of the diaphragm, a pregnant patient requires placement of a chest tube in a more cephalad location to avoid injuring the bowel. The intestines are relocated to the upper part of the abdomen during pregnancy, so they may be shielded by the uterus from blunt trauma. In contrast, the liver and spleen remain in their normal locations under the diaphragm, but are pushed cephalad somewhat in late pregnancy.

Renal and Endocrine Systems

During pregnancy, the renal system is stressed; there is a 30% increase in the glomerular filtration rate (GFR), an increase in kidney size, and relative obstruction of the ureters, leading to **hydroureteronephrosis**. While many women may experience only frequent urination from an increase in GFR, renal outlet obstruction by the growing uterus may cause flank pain and a decrease in urination volume. Placing the patient in a left lateral recumbent position may relieve this flank pain. Renal calculi are no more common in pregnant patients than in nonpregnant patients, and their treatment should remain the same: observation, pain control, and allowing the stone to pass. Nonsteroidal anti-inflammatory drugs (NSAIDs) should be avoided in pregnancy.

Urinary tract infections are more frequent in pregnant patients; untreated early trimester infections will lead to pyelonephritis in the third trimester of pregnancy approximately 50% of the time. Given the significant consequences for the patient and fetus, all pregnant women should be screened for bacteriuria. Patients with chronic renal failure (CRF) can undergo dialysis treatment as needed. Patients with acute renal failure will have issues with compensation of respiratory alkalosis, as discussed earlier, so CCTPs must be aware of changes in their pH levels and treat them accordingly.

At the beginning of conception, the endocrine system goes into overdrive. The pituitary and thyroid glands enlarge, resulting in increased production of estrogen, progesterone, cortisol, and thyroxine. These hormones play important roles in fetal development and in preventing the fetus from aborting; however, in some cases, the elevated hormone levels alter the effectiveness of insulin and result in a condition known as insulin resistance. After 20 weeks' gestation, insulin resistance can lead to elevated blood glucose levels and **gestational diabetes**. Gestational diabetes is treated primarily by diet control and, if needed, insulin.

Thyroid conditions (hyperthyroidism or hypothyroidism) may affect fetal development, because thyroid-releasing hormone can cross the placenta. Consequently, patients with these conditions should be monitored carefully during prenatal care. CCTPs should expect complications during delivery and the possibility of a distressed neonate if a patient who has a thyroid disorder has had poor control of thyroid abnormalities.

Dermatologic Changes

The hormonal changes during pregnancy have an impact on the largest organ of the body—the skin. In addition to acne, pregnant patients can experience **linea nigra**, a darkened line that typically develops from the navel to the pubis, although it may extend for the entire length of the abdomen in some patients. **Chloasma** refers to darkened skin patches on the cheeks and forehead that appear during pregnancy. Finally, some late-term patients present with an itchy rash known as **pruritic urticarial papules and plaques of pregnancy (PUPPP)**, which may be either isolated to one region or more widespread. Patients can be prescribed topical corticosteroid ointments to treat this condition and will occasionally require systemic corticosteroids.

Critical Care Transport of the Pregnant Patient

The role of the CCTP in any critical care transport is to safely and effectively manage, treat, and transport the patient to the facility that can best meet the needs of that patient. The pregnant patient's dynamic physiologic changes and the developing fetus can pose a challenge for any hospital, especially those without obstetric services. In addition, pregnancy can lead to exacerbation of maternal chronic diseases such as coronary heart disease, mitral valve prolapse, and aortic stenosis. Treatment must focus on maintaining the pregnant woman's hemodynamics. CCTPs need to remember that taking care of the pregnant woman means that the fetus is being taken care of as well. In critical cases, treatment of the pregnant patient is no different than that of the nonpregnant patient; for example, treatment of a pregnant patient with an existing cardiovascular condition does not differ from treatment of a nonpregnant patient with this condition. There is one exception: In a patient whose pregnancy is 20 weeks or greater, positioning during transport may be different. The gravid uterus can compress the inferior vena cava when the patient is supine. Performing a left lateral tilt or transporting the patient in the left lateral decubitus position will alleviate this compression.

The CCTP must perform a complete physical exam, including maternal and fetal hemodynamic monitoring. If the patient is in labor, perform external visualization of the perineum to assess for crowning. If delivery is imminent, the CCTP should assist in the delivery. On arrival at the facility, if delivery is imminent, assist with delivery at that facility. Do not begin transport when delivery is imminent.

Cardiac Arrest Management of the Pregnant Patient

When faced with cardiac arrest of a pregnant patient, CCTPs need to remember that the pregnant woman's health is the treatment priority.

When the pregnant patient is treated appropriately, the fetus also benefits. Pregnant patients who go into cardiac arrest typically have a 30% to 80% mortality rate. Common causes of cardiac arrest in pregnancy include hemorrhage, severe hypertension, amniotic fluid embolism, peripartum cardiomyopathy, respiratory arrest, pulmonary embolism, stroke, trauma, and/or infection.

In general, management of cardiac arrest in pregnancy follows similar principles and guidelines as advanced cardiac life support (ACLS) for a nonpregnant patient. The standard rules of cardiopulmonary resuscitation (CPR) apply, with chest compressions in the traditional position and limited interruptions for ventilation. One major difference involves positioning of the uterus. At approximately 20 weeks' gestation, the uterine fundus can be palpated at the umbilicus. At this size, the uterus can cause circulatory problems by decreasing return of blood flow to the heart. If the fundus is palpated at or above the umbilicus, the following technique is recommended: One provider should manually displace the uterus to the left to relieve aortocaval compression and allow for effective venous return and maximal circulation, while another provider continues CPR per BLS/ACLS guidelines. If using an automatic CPR compression device, another option is to tilt the patient to the left lateral decubitus position while automated compressions are ongoing. Manual CPR and intubation are difficult and not as effective when the patient is tilted to the left, so this repositioning should occur only if the providers are using an automated compression device.

Standard guidelines for medication administration in cardiac arrest should be followed with pregnant patients. Epinephrine can be potentially beneficial in these patients, as in other patients in cardiac arrest, although it may harm the fetus. However, in this situation the benefits of such treatment greatly outweigh the risks. Lidocaine may be used especially in the setting of ventricular tachycardia and ventricular fibrillation and has no teratogenic effect on the fetus. Amiodarone can be quite harmful to the fetus, although the benefits outweigh the risks in pregnant patients with refractory ventricular fibrillation or tachycardia. Calcium chloride and calcium gluconate to treat hyperkalemia are both safe in pregnancy. Use the standard doses for pregnant patients. Overall, as in any adult cardiac arrest, survival depends on high-quality CPR and early defibrillation.

Defibrillation remains essential for patients in ventricular fibrillation or pulseless ventricular tachycardia and is safe for the fetus. Use the same settings and paddle positioning as you would for nonpregnant patients. Fetal monitors (discussed later in this chapter) must be disconnected prior to delivering a shock. Pregnant patients become hypoxic more rapidly than nonpregnant patients, so early oxygenation is essential. Provide airway management early; intubate if possible. Intubation should be performed as usual. The only adjustment is manual displacement of the uterus to the left, so as to avoid critical hypotension during intubation.

IV access should be obtained above the diaphragm because blood flow to the heart from below the diaphragm is reduced secondary to uterine compression of the blood vessels. Given the tasks required for performing the resuscitation, the AHA recommends that four BLS responders be present.

Transport Management

Cardiac Arrest in the Pregnant Patient

- Administer CPR.
- Provide early oxygenation.
- Manually displace the uterus to the left to relieve aortocaval compression.
- Defibrillate the patient in ventricular fibrillation and pulseless ventricular tachycardia (but remove the fetal monitor if present).
- Administer resuscitation medications.
- Obtain IV access above the diaphragm if possible.

Fetal Assessment and Monitoring

Several methods can be used to assess and monitor the fetus. Fetal circulation, oxygenation, and heart rate are reviewed first.

Fetal Circulation, Oxygenation, and Heart Rate

Fetal oxygenation depends on a well-oxygenated maternal blood flow to the placenta. Both adequate maternal oxygen saturation and adequate oxygen tension in maternal arterial blood are needed to promote adequate fetal oxygenation. Fetal circulation occurs through the umbilical vein and umbilical arteries **FIGURE 22-5**. The umbilical vein carries highly oxygenated, nutrient-rich blood from the placenta to the fetus’s right atrium via the ductus venosus and the inferior vena cava, and the umbilical arteries carry arteriovenous blood back to the placenta. This system allows the fetal circulation to largely bypass the fetus’s lungs until birth.

Description Description

The oxygen content of fetal blood is lower than that of maternal blood, even though the rate of oxygen consumption by the fetus is nearly twice that of a pregnant woman per unit of weight. However, oxygen will bind preferentially to fetal hemoglobin, as it has a different molecular structure than adult hemoglobin does. The developing fetus obtains its oxygen from the blood of a pregnant woman that passes through the placenta and has only a small reserve of oxygen—usually only 1 to 2 minutes if the maternal supply is cut off or diminished. During uterine contractions, blood flow through the uterine arteries to the placenta is momentarily interrupted or diminished. A healthy fetus with a normal placenta can withstand the stress of labor without having hypoxia develop because sufficient oxygen exchange occurs during the interval between contractions. However, **premature** fetuses or fetuses under stress (small for gestational age, multiple gestation, hypertensive disorders of pregnancy) may not tolerate labor well and are at risk for hypoxia.

The fetal heart rate is sensitive to the changes in oxygen supply. Fetal monitoring is an ongoing indirect assessment of physiologic factors, both extrinsic and intrinsic to the fetus, that affect fetal oxygenation. A decrease in fetal heart rate may be a sign of fetal hypoxia.

TABLE 22-2 summarizes conditions associated with fetal distress during labor that may decrease oxygenation and cause an abnormality in fetal heart rate.

Fetal Assessment

The most difficult job that the CCTP has when transporting a critical pregnant patient is assessing the second patient—the fetus. All patient assessments start with the ABCs. Assessment and monitoring can be extremely challenging in the fetus, but they can be done effectively. Before transporting any pregnant patient, a fetal assessment needs to be performed.

Prior to physical assessment of the fetus, history can be useful in determining fetal health. “Kick counts” are one assessment method. In a pregnancy of 20 weeks’ or greater gestation, fetal movement has been reported as a way to assess fetal health and can be determined by asking the patient how often fetal movements are felt.

Maternal perception of 10 distinct fetal movements within a 2-hour period is considered reassuring.

The next step in assessing fetal health is to evaluate the heart rate. It is not recommended to use a normal stethoscope for this purpose, especially in early-term patients; instead, CCTPs should use a Doppler ultrasonograph starting at 10 weeks' gestation or a fetal stethoscope (fetoscope) after 20 weeks' gestation to detect a heartbeat. First, palpate the abdomen to determine the uterus resting tone and assess for uterine contractions. Next, auscultate the fetal heart rate. The fetus's back is the optimal location to hear the heartbeat; feel for the most rigid part of the fundus to detect the proper location for auscultation. When using a Doppler ultrasonograph, apply conductive gel to the pregnant patient's abdomen at this location before applying the ultrasound transducer, and then listen for the heartbeat. To confirm that you are listening to the fetal heartbeat, take the pregnant patient's radial pulse and compare the rates; the fetal heart rate should be faster.

The normal heart rate of a fetus is between 110 and 160 beats/min **TABLE 22-3**. If a patient is in labor, monitor the fetal heart tones for at least 30 to 60 seconds every 15 minutes and record the results. In a noisy environment, auscultation of fetal heart tones can be challenging, and it may be difficult to determine how the heart rate is changing over time. For this reason, continuous electronic fetal monitoring should be performed during high-risk transports. Continuous electronic fetal monitoring is discussed in the next section.

TABLE 22-3 Fetal Heart Rate Parameters

Rate	Beats/min
Normal	110–160
Abnormal	
Tachycardia	□160

Rate	Beats/min
Bradycardia	<110

© Jones & Bartlett Learning.

An insufficient fetal movement count or nonreassuring heart rate requires further detailed evaluation of the fetus, such as a nonstress test (NST) or biophysical profile (BPP). NST is a more practical approach for the CCTP because it takes a mere 20 minutes to perform, whereas a BPP can take from 30 minutes to an hour. **TABLE 22-4** summarizes the elements of a BPP. An NST requires the CCTP to use electronic fetal monitoring (explained later). A sign of a healthy fetus is at least two accelerations that occur in 20 minutes, where an acceleration is defined as an increase of the heart rate from the fetus's baseline by 15 beats/min for at least 15 seconds. Fewer than two accelerations in 20 minutes may be a sign of nonreassuring fetal status. NSTs require an external fetal monitor with recording capability. BPP requires an ultrasonogram as well as someone to perform and interpret the results.

TABLE 22-4 Elements of a Biophysical Profile

Fetal breathing movements
Fetal body movements
Fetal muscle tone
Amount of amniotic fluid

Note: Each characteristic of the biophysical profile is given a score of 0–2 points, with a maximum score of 10.
Data from Mayo Foundation for Medical Education and Research.

Electronic Fetal Monitoring

Electronic fetal monitoring can be done externally, internally, or both, but during critical care transports it is usually done externally. **External fetal monitoring** uses ultrasonic transducers that are applied to the surface of the pregnant patient's abdomen to assess the fetal heart rate and uterine activity **FIGURE 22-6**. To perform this monitoring, first apply ultrasound gel to the ultrasound (Doppler) transducer. Place the transducer on the maternal abdomen, preferably over the fetal back. Next, palpate the maternal abdomen, and place the tocotransducer (toco) on the abdomen over the upper uterine segment where there is the least amount of maternal tissue between the pressure-sensing button and the uterus. The fetal heart rate data collected via external fetal monitoring is converted into a visual display that can appear on paper, a computer screen, or both.

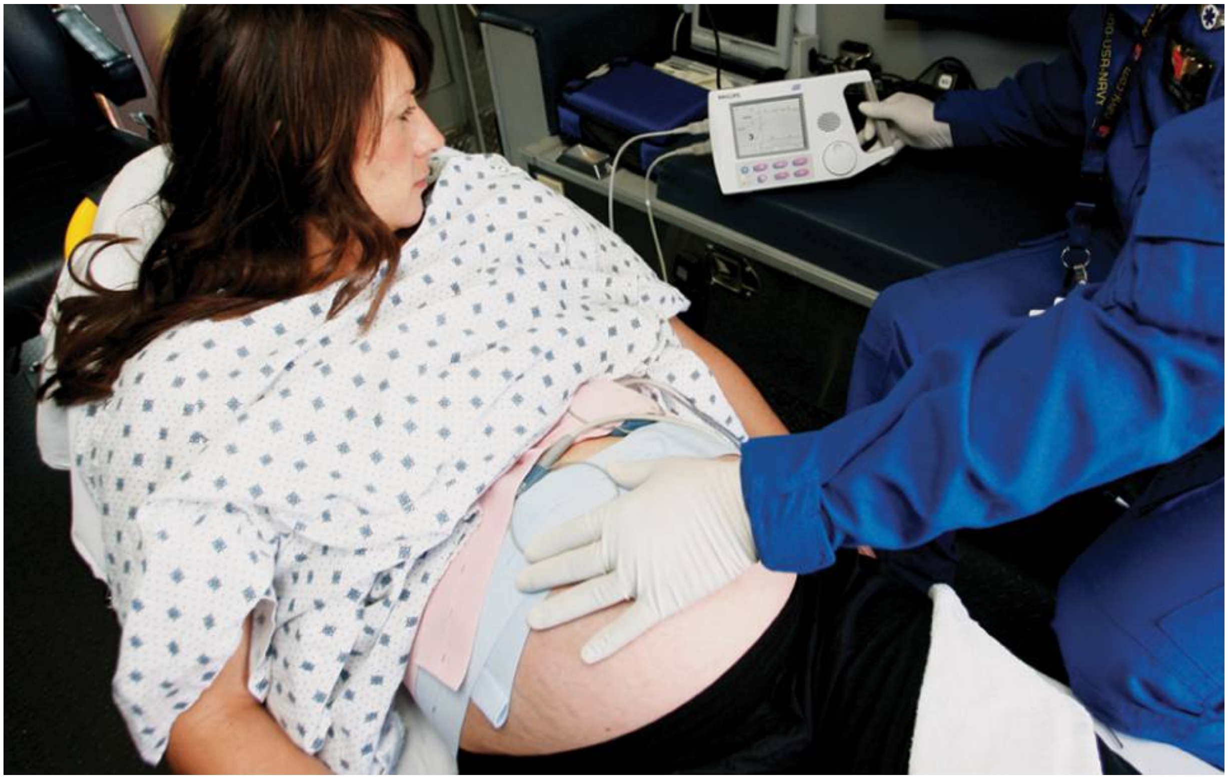

FIGURE 22-6 External fetal monitoring.

© Jones & Bartlett Learning.

Electronic fetal monitoring is recommended for all high-risk interfacility transports. Monitoring enables continuous reporting of the fetal heart rate and uterine contractions by a two-channel strip chart recorder that prints the results **FIGURE 22-7**. An alteration in fetal heart rate correlates with fetal oxygenation.

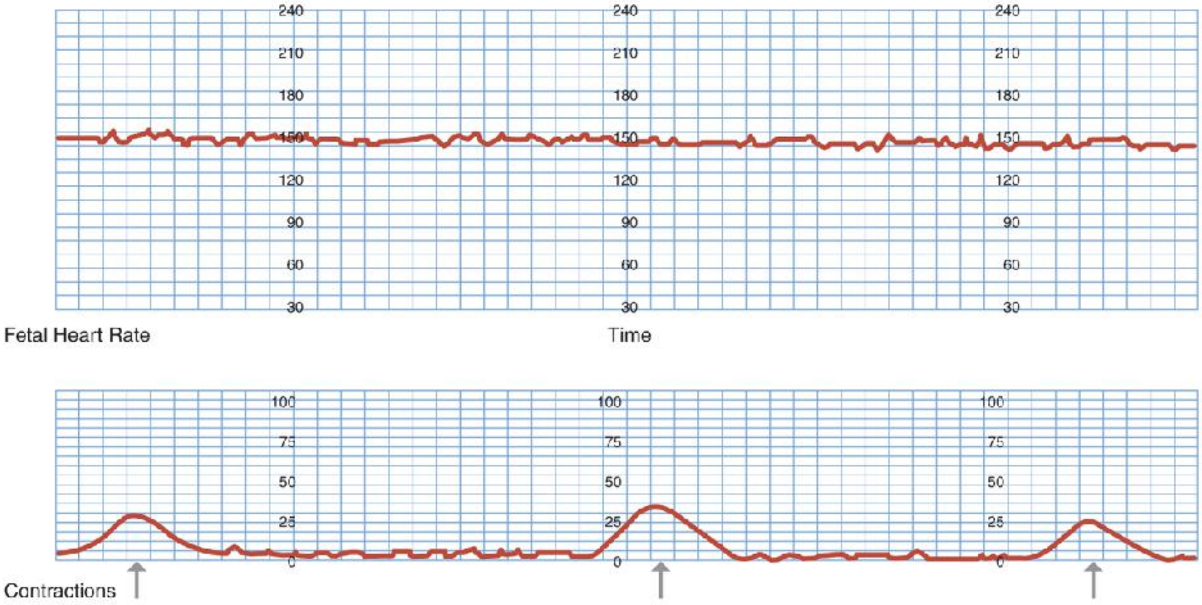

FIGURE 22-7 A fetal monitoring strip showing uterine contractions.

Description

Equipment

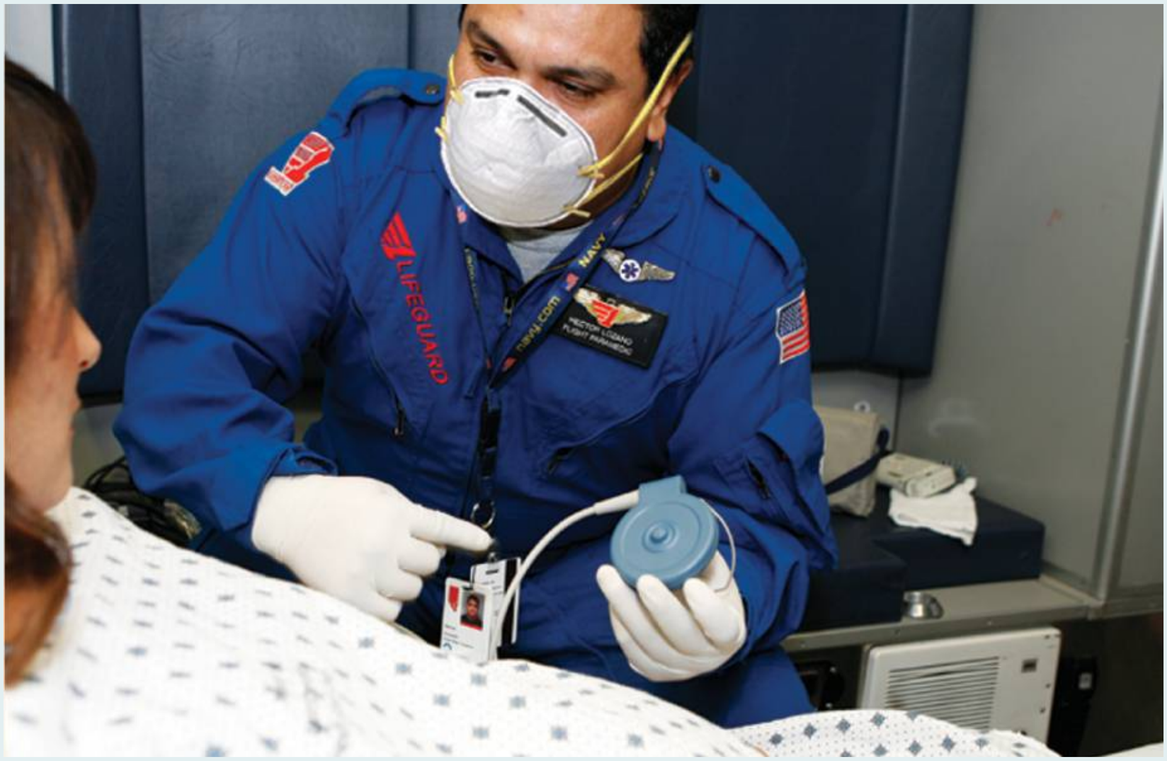
The following equipment is needed to perform external fetal monitoring:

- Fetal monitor
- Conducting gel
- Tracing paper
- Ultrasonographic Doppler
- External uterine activity detector (tocodynamometer)

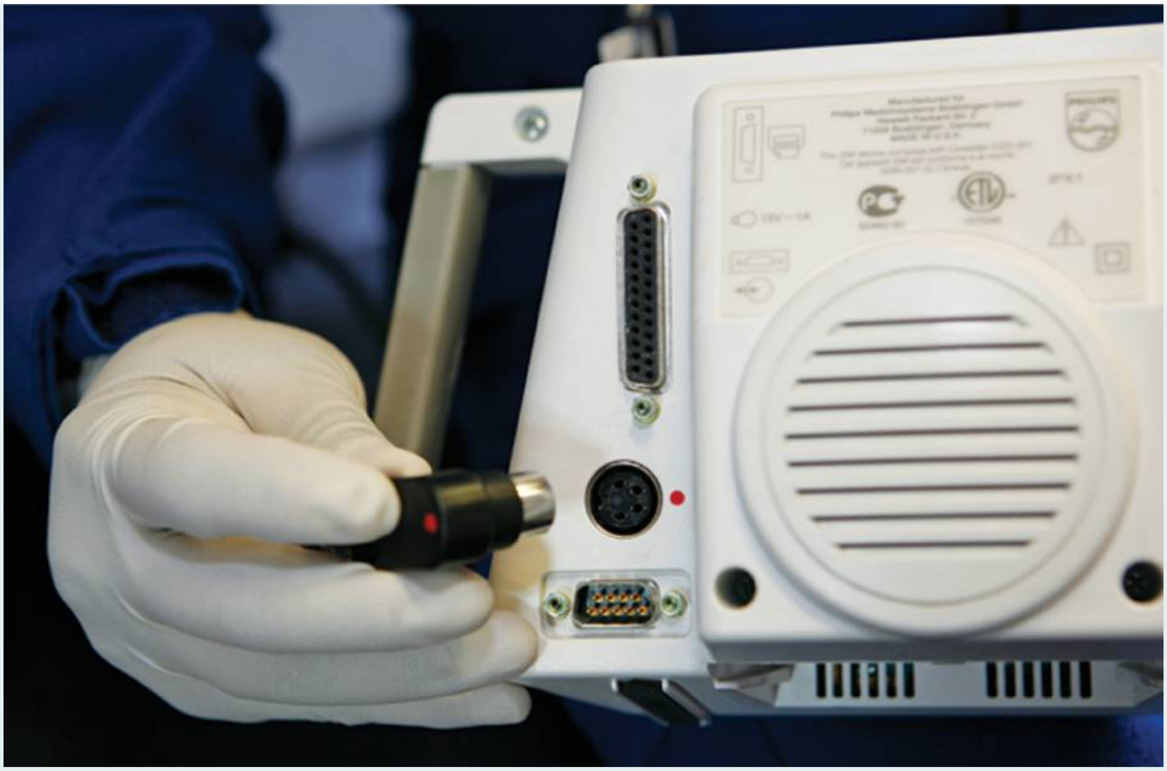
Steps

Skill Drill 22-1 shows the steps for performing fetal monitoring, which are summarized here:

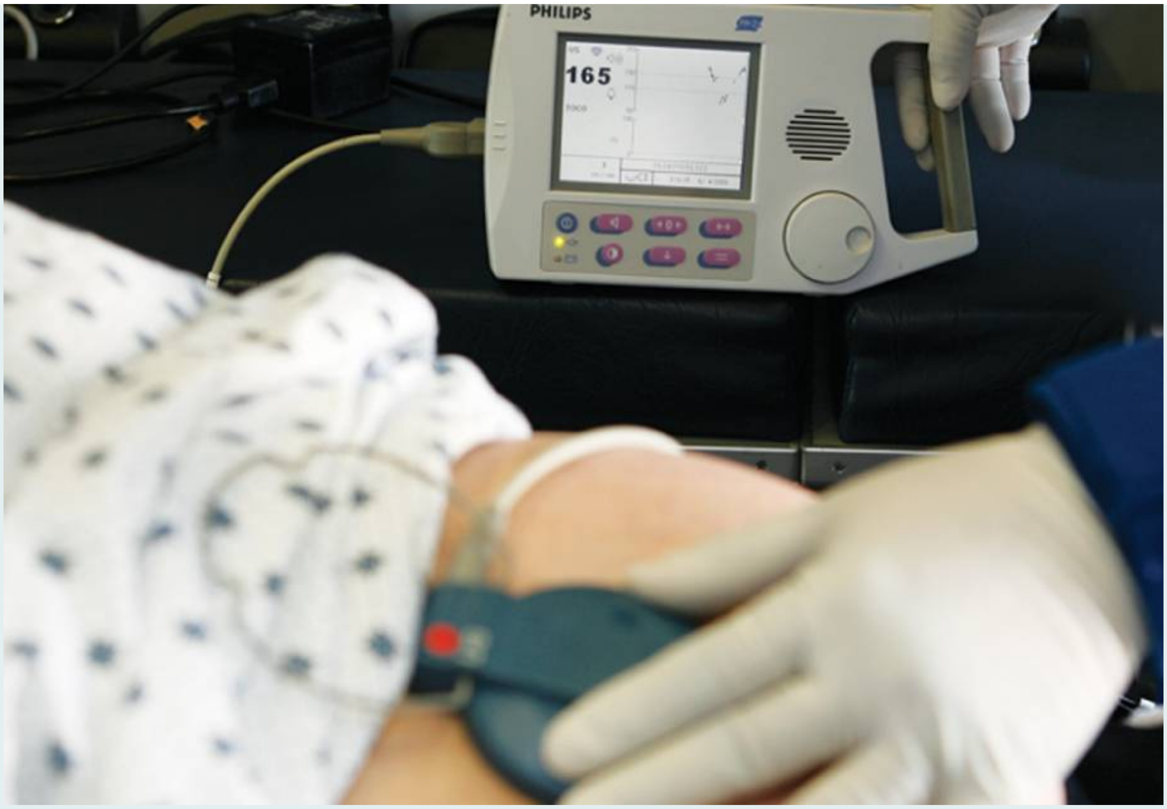
SKILL DRILL 22-1 Fetal Monitoring



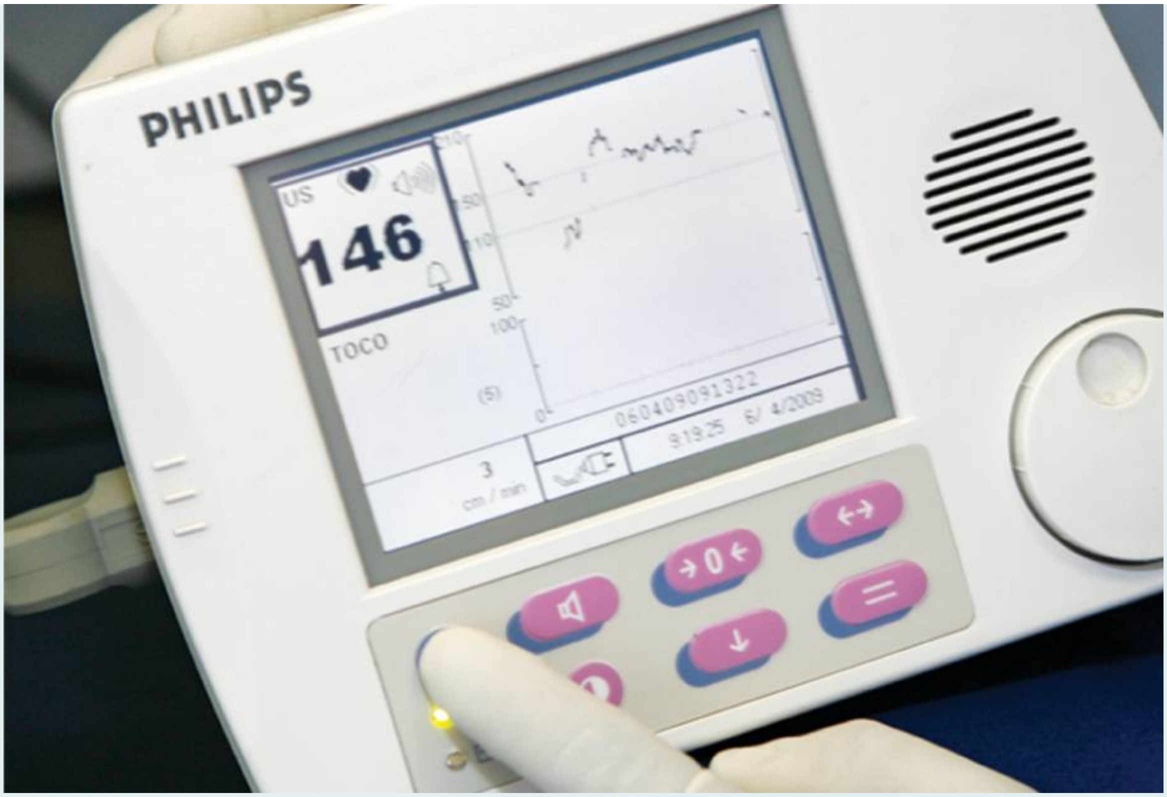
Step 1
Prepare all equipment prior to transport. Explain the procedure to the patient.



Step 2
Connect to the power source.



Step 3
Connect the Doppler ultrasound probe to the patient and adjust the volume. The fetal heart rate should be displayed in green.



Step 4
Make sure that the *Auto Nonstress Test* switch is in the off position. Manually set the uterine Doppler ultrasonograph to zero. Wait for the alerting sound. Press the recording switch. Set the fetal heart tone alarms.

© Jones & Bartlett Learning.

1. Prepare all equipment prior to transport. Introduce yourself and explain the procedure to the patient **Step 1**. Be sure to clarify that this procedure is normal for all transports and that it is essential to monitor the baby's health during the trip.
2. Connect to the power source **Step 2**.
3. Connect the Doppler ultrasound probe to the patient and adjust the volume **Step 3**.
4. Note that the fetal heart rate should be displayed in green.
5. Make sure that the *Auto Nonstress Test* switch is in the off position **Step 4**.

6. Manually set the uterine Doppler ultrasonograph to zero. Wait for the alerting sound.
7. Press the recording switch.
8. Set the fetal heart tone alarms.

Assessment of fetal monitoring strips rarely occurs during transport, although the CCTP may obtain a strip during transport if possible and needed. If internal fetal monitoring was initiated prior to transport, it may be continued en route. Nevertheless, external monitoring should be in place due to the high likelihood of displacement of the internal monitor during movement.

Electronic fetal monitoring is intended to assess the adequacy of fetal oxygenation during labor. As described earlier, oxygen is carried from the internal environment to the fetus by maternal and fetal blood along a pathway that includes the maternal lungs, heart, vasculature, uterus, placenta, and umbilical cord. Interruption of this oxygen pathway at one or more points can result in a fetal heart rate deceleration. Electronic fetal monitoring in the normal patient is expected to show an absence of metabolic acidemia. The goal of standardized electronic fetal monitoring management is to identify and minimize potential sources of preventable error when caring for the pregnant patient and fetus.

Interpretation of monitoring results involves interpreting uterine contractions **TABLE 22-5** along with five fetal heart rate components:

- Baseline heart rate
- Baseline variability
- Accelerations
- Decelerations
- Changes or trends over time

TABLE 22-5 **Five Fetal Heart Rate Components**

Term	**Definition**
Baseline heart rate	• Mean FHR rounded to increments of 5 beats/min during a 10-min period • Baseline must be persistent for a minimum of 2 min in a 10-min segment • Normal FHR baseline: 110–160 beats/min • Tachycardia FHR baseline: □160 beats/min • Bradycardia FHR baseline: <110 beats/min

Baseline variability	• Fluctuations in the FHR baseline that are irregular in amplitude and frequency
	• Four types of variability:
	  • Absent: Amplitude range undetectable
	  • Minimal: Amplitude range detectable but □5 beats/min
	  • Moderate (normal): Amplitude range 6–25 beats/min
	  • Marked: Amplitude range □25 beats/min

Acceleration	• A visually apparent abrupt increase (onset to peak in less than 30 s) in the FHR • At 32 weeks' gestation and beyond, acceleration has a peak □15 beats/min above baseline, with duration of 15 s or more but less than 2 min from onset to return • Before 32 weeks' gestation, an acceleration has a peak □10 beats/min above baseline, with a duration of 10 s or more but less than 2 min from onset to return • Prolonged acceleration lasts □2 min but <10 min in duration • If an acceleration lasts □10 min, it is a baseline change
Early deceleration	• Visually apparent, usually symmetric gradual decrease and return of the FHR to baseline associated with a contraction • Gradual FHR decrease from onset to nadir of the deceleration associated with a contraction • Nadir of the deceleration occurs at the same time as peak of the contraction

Term	Definition
Late deceleration	• Visually apparent, usually symmetric gradual decrease and return of the FHR to baseline associated with a contraction • Delayed onset, with nadir always occurring after peak of the contraction
Variable deceleration	• Abrupt decrease in FHR below the baseline of □15 beats/min lasting □15 s but <2 min
Prolonged deceleration	• Visually apparent decrease in FHR below the baseline • Decrease in FHR from baseline □15 beats/min lasting □2 min but <10 min in duration • Decrease in FHR lasting □10 min is considered a baseline change
Sinusoidal pattern	• Visually apparent, smooth, sine wave-like undulating pattern in FHR baseline with a cycle frequency of 3–5 cycles/min that persists for □20 min

Abbreviation: FHR, fetal heart rate
Data from Miller DA. Intrapartum fetal evaluation. In: Gabbe SG, Niebyl JR, Simpson JL, et al., eds. *Obstetrics: Normal and Problem Pregnancies*. 7th ed. Philadelphia, PA: Elsevier; 2017.

Uterine contractions are defined as the number of contractions present in a 10-minute time frame averaged over 30 minutes. The CCTP should assess for contraction frequency, duration, intensity, and resting tone between contractions **TABLE 22-6**. Assessment of contractions can be done by palpation of the abdomen, or by palpation in conjunction with use of an external tocodynamometer or intrauterine pressure catheter. The tocodynamometer is part of electronic fetal monitoring and externally detects abdominal pressure of the contour changes resulting from uterine contractions. A normal contraction pattern is defined as 5 or fewer contractions in 10 minutes, averaged over a 30-minute time frame **FIGURE 22-8A**.

TABLE 22-6 Assessment of Uterine Contractions

Contraction Component Assessment	Defined
Frequency	Measured from the beginning of one contraction to the beginning of the next; has units of minutes.
Duration	The length of the contraction from start to end of the contraction; has units of seconds.
Intensity	The strength of the contraction; described as mild, moderate, or strong by palpation or measured in units of millimeters of mercury if an intrauterine pressure catheter is used.
Resting tone	Assessed in the absence of contractions or between contractions. Using direct palpation, the abdomen is described as soft or hard.

FIGURE 22-8 Uterine contraction patterns. **A.** Normal uterine activity. **B.** Tachysystole uterine activity. **C.** Normal Category I tracing. **D.** Sinusoidal pattern.

Courtesy iSimulate, www.isimulate.com.

Tachysystole is defined as more than 5 contractions in 10 minutes, averaged over a 30-minute time frame **FIGURE 22-8B**. Tachysystole increases the amount of time that blood in the intervillous spaces remains in stasis, reducing the potential for maternal-fetal exchange of respiratory gases. The intervillous space contains the vessels that communicate between the mother and fetus. Tachysystole can occur from exogenous stimulation—for example, with use of cervical ripening medications—or from internal production of endogenous agents such as maternal oxytocin or prostaglandin. It is important to recognize and intervene when this abnormal pattern is observed.

Once uterine contractions are calculated, the next section of external monitoring involves using the baseline heart rate, baseline variability, accelerations, decelerations, and changes over time to identify tracings as Category I, II, or III.

A Category I tracing **FIGURE 22-8C** is considered normal, indicating normal fetal acid–base status at that time. It meets the following criteria:

- Baseline rate of 110–160 beats/min
- Moderate variability (6–25 beats/min)
- No late or variable decelerations
- Present or absent early decelerations
- Present or absent accelerations

FIGURE 22-9 shows some external fetal monitoring results related to fetal heart rate variability. **FIGURE 22-10** presents results related to accelerations and decelerations.

FIGURE 22-10 External fetal monitoring results: accelerations and decelerations. **A.** Early decelerations. **B.** Variable decelerations. **C.** Late decelerations. **D.** Prolonged decelerations.

Courtesy iSimulate, www.isimulate.com.

Moderate variability or accelerations in the fetal heart rate reliably predict the absence of fetal **metabolic acidosis** at the time they are observed. In contrast, minimal or absent variability does *not* reliably predict the presence of metabolic acidosis. Likewise, the absence of accelerations does *not* reliably predict the presence of **metabolic acidemia** or hypoxia.

Bradycardia is a concerning finding, as it suggests congenital heart block or serious fetal compromise. Tachycardia can be a sign of maternal infection, cardiac arrhythmias, maternal drug administration, or fetal compromise.

A Category III tracing has at least one of the following components:

- Absent variability with any of the following:
    - Recurrent late decelerations
    - Recurrent variable decelerations
    - Bradycardia
- A sinusoidal pattern **FIGURE 22-8D**

Late and recurrent variable decelerations are considered recurrent when they are observed in at least 50% of contractions within a 20-minute period.

Category III tracings are considered abnormal and require emergent measures to improve fetal oxygenation and/or to expedite delivery to reduce neonatal morbidity and mortality. Continued Category III fetal heart rate patterns herald an increased risk of fetal hypoxia and acidosis, which can lead to cerebral palsy and hypoxic ischemic encephalopathies.

Category II tracings represent fetal heart rate patterns that do not meet the classification criteria for either Category I (normal) or Category III (abnormal); hence, they are considered indeterminate or atypical. The potential for development of fetal acidosis varies widely across the spectrum of Category II tracings. While they have an uncertain prognosis, such fetal heart rate patterns may be observed for prolonged periods of time, which make them very challenging to evaluate and manage.

In summation, if the CCTP observes a Category I tracing during external fetal monitoring, this is grossly reassuring for the absence of significant hypoxia or acidosis in the fetus. A Category III tracing requires urgent transport and evaluation by an obstetrician for possible emergent delivery.

Complications of Pregnancy

Early Pregnancy Loss

Early pregnancy loss (miscarriage, spontaneous abortion) is the loss of a fertilized developing ovum. Such losses are common in early pregnancy, with approximately 30% of all pregnancies ending prior to 20 weeks' gestation. A significant portion of those losses will occur prior to the woman becoming aware of the pregnancy. Loss of a fetus after 20 weeks' gestation is called intrauterine fetal demise (IUFD). Approximately 80% of all early pregnancy losses occur during the first trimester.

An estimated 50% of early pregnancy losses are due to chromosomal abnormalities in the fetus. Patients often present with vaginal bleeding or cramping. Assessment of the female patient with vaginal bleeding or abdominal pain focuses on identifying whether the patient is having an early pregnancy loss or an ectopic pregnancy. The definitive diagnosis can be made only with ultrasonography.

CCTPs should document the patient's blood loss by recording the number of sanitary pads soaked during transport and relay this information to the receiving facility. Vaginal bleeding that soaks more than one pad every hour is cause for concern. Hypotension is treated with isotonic fluid volume replacement such as lactated Ringer solution or normal saline. Treatment for women having an early pregnancy loss also includes providing comfort and emotional support.

If patients do not completely expel all of the products of conception, this retention puts them at higher risk of continued bleeding or infection. These patients may require a **dilation and curettage (D&C)**. In this surgical procedure, the physician dilates the cervix with special cervical dilators and curettes the uterine lining, usually with a suction device, to remove the remaining products of conception. The goal is to reduce the risk of infection caused by tissue left behind on the uterine wall. Such patients should be transported to a facility where this procedure can be performed within 24 hours.

As with any invasive procedure, there is a risk for infection with D&C. CCTPs need to watch patients who have undergone this procedure for the signs of postoperative infection, including fever, chills, pelvic discomfort, tachypnea, and lethargy.

Signs and Symptoms

Early Pregnancy Loss

- Vaginal bleeding
- Cramping
- Abdominal pain
- Hypotension

Differential Diagnosis

Early Pregnancy Loss

- Abruptio placentae
- Ectopic pregnancy
- Placenta previa

Transport Management

Early Pregnancy Loss

- Provide volume replacement with isotonic fluids.
- Provide comfort and emotional support.
- Apply sanitary pads, and count how many become saturated.

Ectopic Pregnancy

An **ectopic pregnancy** is a pregnancy that implants outside of the uterus. Complications of ectopic pregnancies can be life threatening for the woman. Ectopic pregnancies represent 1% to 2% of all pregnancies and account for 9% of pregnancy-related deaths in the United States. Most ectopic pregnancies occur in the fallopian tubes, although a small percentage can implant in the peritoneum, in an ovary, in the cervix, or interstitially. When the fertilized egg attempts to implant in tissue other than the uterus, it causes bleeding and damage to the underlying tissue. Women of childbearing years with sudden onset of abdominal pain or uncommon vaginal bleeding must be considered to have an ectopic pregnancy. The greatest risk factor for the occurrence of an ectopic pregnancy is pelvic inflammatory disease. Severe pelvic inflammatory disease can cause tubule scarring, which destroys the cilia that would otherwise guide the ovum to the uterus. This scarring results in a higher risk for ectopic pregnancy. Other risk factors include tubal ligation, reversed ligation, previous ectopic pregnancy, current intrauterine device use, and smoking.

Treatment for ectopic pregnancy can be medical or surgical. For patients who meet certain criteria, medical therapy with methotrexate is possible. For those who do not meet these criteria or who have other contraindications to methotrexate, surgery is indicated.

Signs and Symptoms

Ectopic Pregnancy

- Abdominal pain (sudden onset)
- Vaginal bleeding

Differential Diagnosis

Ectopic Pregnancy

- Abruptio placentae

- Placenta previa
- Preterm labor
- Early pregnancy loss
- Ovarian cyst
- Ovarian torsion
- Appendicitis

Transport Management

Ectopic Pregnancy

- Continue supportive therapy.
- Obtain IV access.
- Administer IV fluids if the patient has hypotension.

Bleeding

Vaginal bleeding in early pregnancy may indicate an early pregnancy loss or an ectopic pregnancy. Bleeding in the second and third trimesters of pregnancy is often associated with significant pathologic conditions that may endanger the lives of both the woman and the fetus.

As the pregnant woman approaches term, as much as 30% of the maternal cardiac output is going to the uterus, fetus, and placenta. Thus, it is easy to understand how rapidly the patient can bleed and become hemodynamically unstable. Three major causes of life-threatening bleeding in pregnant patients are abruptio placentae, placenta previa, and uterine rupture. Because of the high risk of maternal and fetal death associated with any of these clinical entities, any vaginal bleeding during the third trimester of pregnancy must be regarded as a dire medical emergency until proven otherwise. The CCTP should suspect placenta previa or abruptio placentae in any patient with third-trimester abdominal pain or vaginal bleeding. The classic teaching is that placenta previa is associated with “painless” vaginal bleeding, whereas abruptio placentae is associated with “painful” vaginal bleeding.

Regardless of the cause of the vaginal bleeding, patient management is the same. Place the woman on her left side in a recumbent position to maximize blood return to the heart and prevent supine hypotensive syndrome. Administer oxygen if the saturation is less than 92%, and place at least one large-bore IV line. Lactated Ringer solution is the optimal treatment, but normal saline can be given as an alternative in 250-mL boluses and titrated to the patient’s hemodynamic status. BP should be maintained at no less than 90 mm Hg systolic. Rapid transport is required, with the receiving hospital being notified of the nature of the problem as well as any changes in the patient’s condition that occur en route. *Under no circumstances should the CCTP perform an internal vaginal exam*.

Abruptio Placentae

Abruptio placentae (also called placental abruption) is the premature separation of a normally implanted placenta from the uterine wall **FIGURE 22-11**. It occurs in 1% of pregnancies, leading to a neonatal death in 10% to 30% of cases. Abruptio placentae accounts for 30% of life-threatening vaginal bleeding in the second half of pregnancy. This condition can be either spontaneous or a result of trauma. Even minor trauma, such as a fall from standing, can cause an abruption.

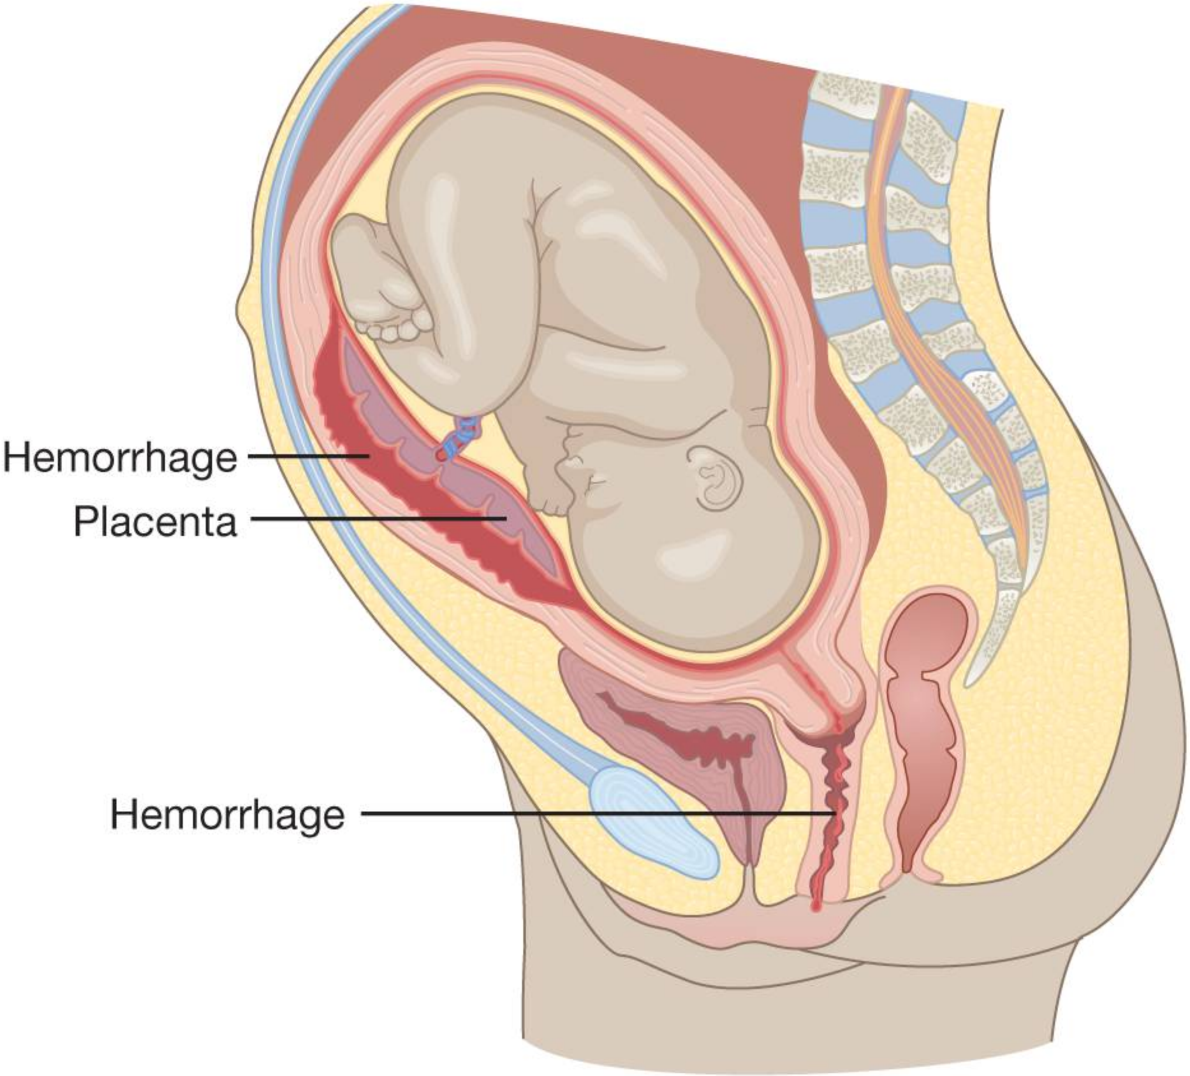

FIGURE 22-11 Abruptio placentae is a premature separation from the uterine wall, with resultant hemorrhage between the wall and the placenta.

© Jones & Bartlett Learning.

Risk factors associated with spontaneous abruptio placentae include tobacco use, cocaine use, chronic hypertension, preeclampsia, thrombophilias, and abruption in a previous pregnancy. Bleeding from spontaneous abruptio placentae usually occurs late in the third trimester of pregnancy, with a peak incidence at 37 weeks.

Abruptio placentae associated with trauma is less common and is usually due to direct trauma to the abdomen. However, it is a complication in 1% to 5% of minor injuries that occur during pregnancy and as many as 40% to 50% of major trauma injuries that occur during pregnancy. Because the placenta is less elastic than the uterus to which it is attached, when a pregnant woman is subjected to trauma that stretches or deforms the uterus, the relatively inelastic placenta separates from the uterine wall, causing abruption. Fetal mortality is high with traumatic abruption, ranging from 67% to 75%. Ultrasonography is useful to assess for fetal well-being; however, its ability to detect an abruption is limited.

Regardless of the cause, the presenting signs and symptoms of abruptio placentae include abdominal pain, back pain, uterine tenderness, and usually vaginal bleeding. On some occasions, an abruption may occur without any visible vaginal bleeding; that is, the abruption is concealed. The separation may occur in such a way that the bleeding is contained by the part of the placenta attached to the uterine wall. In such a case, the amount of vaginal bleeding may be small or no blood may be evident, and the patient’s condition may be easily mistaken for premature labor. The amount of visible blood does not directly correlate with degree of abruption, as shock may ensue from the concealed blood loss.

On physical exam, the abdomen is usually tender and the uterus is rigid on palpation. When vaginal blood is present, it may be bright, dark, or mixed with amniotic fluid. The pregnant patient may exhibit signs of shock out of proportion to the amount of vaginal bleeding.

Important factors in the management of the pregnant patient with suspected abruptio placentae are the fetal status and the presence or absence of labor. Most women who experience abruptio placentae spontaneously go into labor. The same procedures for all vaginal bleeding in the third trimester of pregnancy should be followed, with a focus on oxygenation and administration of IV fluids to maintain hemodynamic stability. Place the patient on her left side in a recumbent position, give oxygen to maintain saturation of 92% or greater, establish at least one large-bore IV line and administer lactated Ringer solution or normal saline, and provide rapid transport. Consider administering tranexamic acid (TXA) where local protocols allow.

Signs and Symptoms

Abruptio Placentae

- Vaginal bleeding
- Abdominal pain
- Back pain
- Uterine tenderness/contractions of severe intensity
- Signs of shock
- Lack of fetal heart sounds

Differential Diagnosis

Abruptio Placentae

- Ectopic pregnancy
- Placenta previa
- Preterm labor
- Early pregnancy loss

Transport Management

Abruptio Placentae

- Place the patient on her left side, in recumbent position.
- Provide oxygenation to maintain oxygen saturation of 92% or greater.
- Administer IV fluids.
- Provide rapid transport.
- Consider TXA where permitted.

Placenta Previa

In placenta previa, the placenta is implanted low in the uterus and partially or completely covers the cervical canal **FIGURE 22-12**. Placenta previa can be seen on approximately 4% of ultrasonographic studies performed at 20 to 24 weeks' gestation but occurs at term in only 0.4% of pregnancies. Bleeding usually occurs late in the third trimester of pregnancy, as the cervix begins to dilate in preparation for delivery.

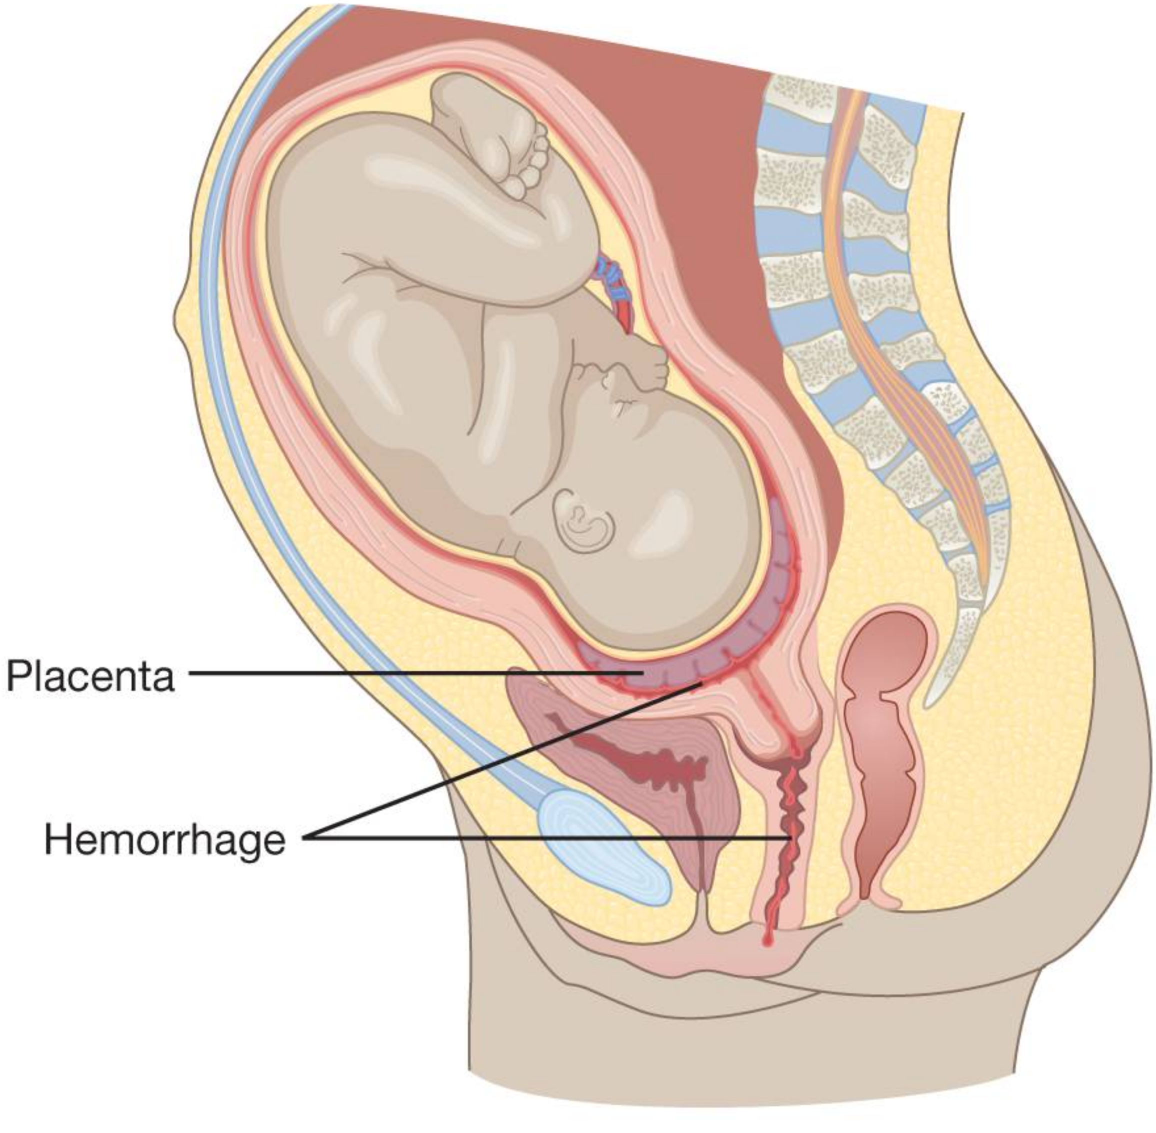

FIGURE 22-12 Positioning of the placenta in placenta previa.

© Jones & Bartlett Learning.

The usual presenting complaint of the woman with placenta previa is bright red vaginal bleeding. In contrast to abruptio placentae, the bleeding in placenta previa is painless and the uterus remains soft.

Treatment of the patient with suspected placenta previa is the same as for all patients with third-trimester bleeding. CCTPs need to make the mother the priority. Maintaining her hemodynamics with IV fluids and oxygenation will benefit the fetus as well. However, CCTPs must be cautious when examining the patient with placenta previa. Because the placenta is precariously placed over the cervical opening, *no* internal examination of the vagina or cervix should be performed. Treatment should be accomplished with minimal movement. Electronic fetal monitoring should be performed, again with minimal patient movement. Administration of TXA may be appropriate if the local protocols permit it.

Signs and Symptoms

Placenta Previa

- Bright red vaginal bleeding
- Lack of abdominal pain

Differential Diagnosis

Placenta Previa

- Abruptio placentae
- Ectopic pregnancy
- Preterm labor
- Early pregnancy loss

Transport Management

Placenta Previa

- Administer IV fluids.
- Administer oxygen.
- Allow minimal movement.

- Perform electronic fetal monitoring.
- Consider TXA where permitted.

Uterine Rupture

Uterine rupture is a cause of catastrophic bleeding in the second half of pregnancy. Rupture associated with trauma is relatively uncommon. Maternal mortality from trauma-induced uterine rupture is approximately 10%, whereas fetal mortality approaches 100%. Uterine rupture should be suspected in the pregnant trauma patient who has loss of palpable uterine contour, has easily palpated fetal parts, and has severe abdominal pain. As with any pregnant patient who experiences trauma, initial management is directed at the resuscitation and stabilization of the pregnant patient.

Uterine rupture can also occur without trauma, in which case it is almost always associated with labor. A weakened portion of the uterine wall is at risk for rupture at any time during the pregnancy. Women who are at highest risk for this condition are those who have had previous uterine surgery, including cesarean section.

Incomplete rupture is usually diagnosed at the time of cesarean section and is an incidental finding; however, complete ruptures can be catastrophic. Signs or symptoms of uterine rupture include abnormal maternal vital signs, sudden or worsening abdominal pain, abnormal fetal heart rate, loss of fetal station (fetus appears to be retreating back into the uterus), abnormal uterine contractions, vaginal bleeding, and hematuria (rupture extends into the bladder).

Fetal monitoring in the setting of uterine rupture will show fetal distress such as fetal bradycardia and increased uterine contractions. In some cases, the fetus and placenta may exit the uterus into the abdominal cavity.

Treatment of spontaneous uterine rupture consists of volume resuscitation and oxygen. CCTPs need to prepare the patient for surgery, because definitive care involves surgery and cesarean section. During transport, consider administering IV fluids and whole blood transfusions to ensure hemodynamic stability, in addition to optimizing oxygenation and providing advanced airway management.

Signs and Symptoms

Uterine Rupture

- Loss of palpable uterine contour
- Easily palpated fetal parts
- Sharp, tearing abdominal pain
- Hemodynamic instability
- Fetal heart rate abnormalities
- Vaginal bleeding

Transport Management

Uterine Rupture

- Perform electronic fetal monitoring.
- Provide volume resuscitation.
- Administer oxygen to maintain oxygen saturation of 92% or greater.
- Provide rapid transport.

Medical Conditions During Pregnancy

Hypertension complicating pregnancy is classified into four types: chronic hypertension, chronic hypertension with superimposed preeclampsia-eclampsia, preeclampsia-eclampsia, and gestational hypertension. Hypertensive disorders of pregnancy, including preeclampsia, complicate 10% of pregnancies. If such disorders are left untreated, dangerous—if not fatal—consequences for the woman and the fetus can ensue. Risk factors include multiple gestations (twins, triplets), first-time pregnancies, and maternal chronic hypertension.

Hypertensive Disorders of Pregnancy

The hypertensive disorders of pregnancy include the following:

- Gestational hypertension
- Preeclampsia without severe features
- Preeclampsia with severe features
- Eclampsia
- HELLP syndrome (hemolysis, elevated liver enzymes, low platelets)

All of these disorders can increase maternal and fetal morbidity and mortality. They are, in fact, the leading cause of maternal and perinatal mortality worldwide. They can be a new-onset condition or can occur in women with existing hypertension. In general, patients who have one of these disorders superimposed on existing hypertension are likely to have worse outcomes.

Gestational Hypertension

Gestational hypertension is the development of hypertension (BP of 140/90 mm Hg) after 20 weeks' gestation in a previously normotensive patient. BP returns to normal after delivery. The definition of this diagnosis includes two separate measurements of BP at least 4 hours apart. Gestational hypertension is managed in a similar fashion to preeclampsia. Fifty percent of women with gestational hypertension will progress to preeclampsia. Women with BP in the severe range (160/110 mm Hg or higher) are managed in a similar fashion to women with preeclampsia with severe features.

Preeclampsia

As mentioned earlier, **preeclampsia** is classified into two types, based on whether it presents with severe features. *Preeclampsia without severe features* is hypertension developing after 20 weeks' gestation, defined as a systolic blood pressure of 140 mm Hg and a diastolic blood pressure of 90 mm Hg. Preeclampsia can develop up to 12 weeks postpartum. In addition, patients may develop new-onset **proteinuria** (protein in the urine). In the absence of proteinuria, preeclampsia can be diagnosed as hypertension in association with **thrombocytopenia** (platelet count less than 100,000/µL), impaired liver function (liver transaminases elevated to twice normal values), new-onset laboratory-documented renal insufficiency (creatinine level of 1.1 mg/dL or a doubling of the patient's baseline creatinine), pulmonary edema, or new-onset visual or cerebral disturbances.

These patients may be treated with magnesium sulfate for seizure prophylaxis, depending on local practice patterns. The loading dose of magnesium is 4 to 6 g given IV over 15 to 20 minutes. High levels of magnesium can result in respiratory depression and cardiac arrest. An early sign of magnesium toxicity is the loss of deep tendon reflexes. If the patient has respiratory depression, stop the magnesium infusion, assist with ventilation, and administer calcium gluconate. If the patient goes into cardiac arrest, proceed with ACLS and give calcium gluconate.

Preeclampsia with severe features has many of the same diagnostic features as preeclampsia without severe features. However, the BP is in the severe range—160/110 mm Hg or higher. These patients are at higher risk of progressing to eclampsia and should be treated with magnesium sulfate to prevent seizures. Even more important than loading with magnesium is controlling the patient’s BP. The longer the BP remains elevated, the greater the incidence of stroke. These patients should receive antihypertensive medications. Labetalol, hydralazine, and nifedipine can all be used safely in pregnancy. The goal BP is approximately 140/90 mm Hg. BP should be reassessed every 10 to 15 minutes. If the BP is not at goal, repeat the dose of the antihypertensive medication if local protocols permit. If the maximum dose has been given, additional medication may be required.

CONTROVERSIES

The use of magnesium sulfate for seizure prophylaxis for patients with preeclampsia without severe features is somewhat controversial. It is dictated by local practice patterns. Defer to your local protocols.

Signs and Symptoms

Preeclampsia

- Hypertension
- Edema or pathologic edema
- Proteinuria
- Headache
- Visual disturbances
- Abdominal pain

Differential Diagnosis

Preeclampsia

- Preexisting hypertension
- Migraine

Transport Management

Preeclampsia

- Place the patient on her left side.
- Obtain IV access.
- Control BP if in severe range.
- Prevent/control seizures.
- Administer oxygen.
- Administer magnesium sulfate if seizures occur.

Eclampsia

Eclampsia is defined as new-onset seizures in a woman at greater than 20 weeks' gestation, and who usually has one of the hypertensive disorders of pregnancy. However, eclampsia can occur without a previous diagnosis of preeclampsia or HELLP syndrome. Preeclampsia may progress rapidly to eclampsia before, during, or after delivery, especially during the first 48 hours postpartum. Both preeclampsia and eclampsia can present up to 6 weeks postpartum. Eclampsia should always be considered in any pregnant or postpartum patient who is seizing. Even in patients with a known seizure disorder, if they have a seizure and are 20 weeks' gestation or greater, they should be considered to have eclampsia until proven otherwise.

The only true treatment for eclampsia is delivery. Maternal complications from eclampsia include permanent central nervous system (CNS) damage, stroke, renal insufficiency, and death.

The management goal for the CCTP caring for a patient with eclampsia is to prevent any additional seizures. This is accomplished by administering 4 to 6 g of magnesium sulfate over 15 to 20 minutes, then continued as a drip at 2 to 4 g/h. Magnesium sulfate is the drug of choice for treating seizures due to eclampsia; it is a better choice than phenytoin, benzodiazepines, and nimodipine for this indication. The actual mechanism by which magnesium achieves its effects is poorly understood. Notably, it is a poor antihypertensive medication and should not be used in that capacity.

Seizures may occur suddenly and should be anticipated. If they occur, routine seizure management and protection of the patient should be initiated first. Ensure a patent airway and adequate oxygenation. Position the patient on the left side (if possible) and protect the patient from additional physical injury. Check glucose levels at the point of care. Consider the administration of magnesium sulfate based on the transfer orders or consultation with medical direction. This therapy should always be accompanied by clinical observation for loss of reflexes, respiratory depression, and, if the patient is not currently experiencing a seizure, CNS depression. The antidote for magnesium sulfate toxicity is calcium gluconate. Alternatively, benzodiazepines or phenytoin can be used to initially terminate the seizure, with magnesium sulfate administered immediately thereafter. Additional magnesium sulfate should first be considered for a recurrent seizure as long as no signs of magnesium toxicity are present.

If magnesium sulfate is not available, standard seizure therapy may be followed, which includes the use of diazepam or other benzodiazepines. Even though benzodiazepines are effective anticonvulsants, they are not as effective as magnesium sulfate for the treatment of eclampsia. If benzodiazepines are given, it is imperative to report this treatment to the receiving providers. Neonates can experience respiratory depression from these medications and may require additional support at the time of delivery.

Signs and Symptoms

Eclampsia

- Severe headache
- Scotomata (visual changes)
- Hyperreflexia (overactive reflexes)
- Epigastric pain

- Anxiety

Differential Diagnosis

Eclampsia

- Seizure disorder
- Hypoglycemia
- Alcohol withdrawal

Transport Management

Eclampsia

- Place the patient on her left side.
- Obtain IV access.
- Control BP if in severe range.
- Prevent/control seizures.
- Administer oxygen.
- Administer magnesium sulfate

HELLP Syndrome

HELLP syndrome occurs during the latter stages of pregnancy, usually after 20 weeks' gestation. This syndrome is named after its clinical findings—namely, hemolytic anemia, elevated liver enzyme levels, and a low platelet count.

The cause of HELLP syndrome is unknown, but it appears to be a severe form of preeclampsia coupled with activation of the coagulation system, leading to multiorgan dysfunction syndrome (discussed in Chapter 10, *Resuscitation, Shock, and Blood Products*). Patients most often present with right upper quadrant pain and generalized malaise. Fifty percent will present with nausea and vomiting. Hypertension and proteinuria are present in 85% of cases but absent in 15% of cases, making the diagnosis more elusive.

Treatment may include blood and blood products, antihypertensives, and magnesium (for seizure prophylaxis). However, definitive treatment can be accomplished only with delivery of the fetus. CCTPs need to be aware that HELLP syndrome occurs in 10% of postpartum women.

Signs and Symptoms

HELLP Syndrome

- Hemolytic anemia
- Elevated liver enzyme levels
- Low platelet count
- Abdominal pain
- Blurred vision
- Headache
- Edema

Differential Diagnosis

HELLP Syndrome

- Cholecystitis
- Hepatitis
- Idiopathic thrombocytopenia

Transport Management

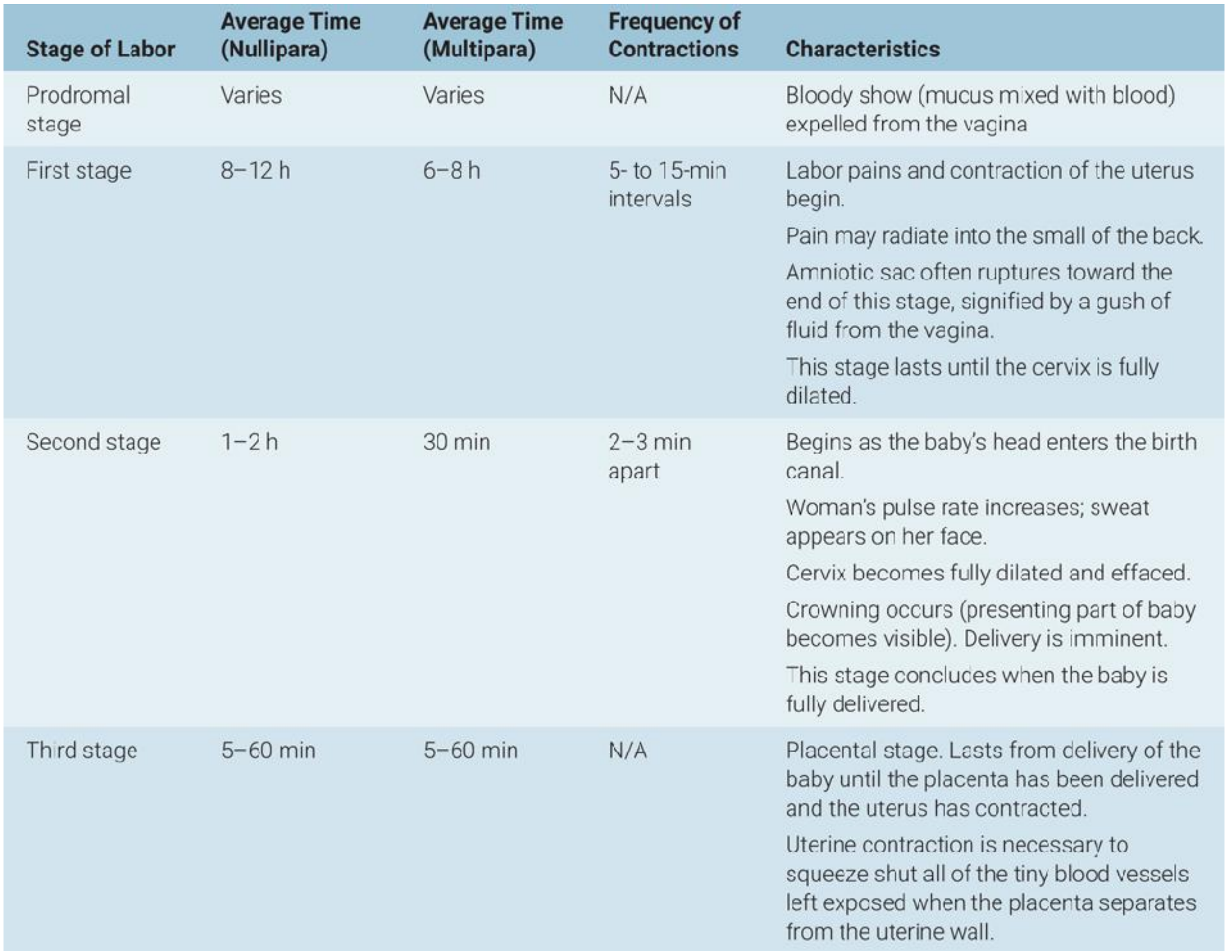
HELLP Syndrome

- Consider administering blood/blood products (fresh-frozen plasma [FFP]).
- Manage BP.
- Administer magnesium sulfate (for seizure prophylaxis).

Complications During Labor

Normal labor includes a prodromal stage plus three distinct active stages, whose durations depend partly on whether it is the patient's first pregnancy (nullipara). **TABLE 22-7** reviews the stages of labor.

TABLE 22-7 | **Stages of Labor**



Stage of Labor	Average Time (Nullipara)	Average Time (Multipara)	Frequency of Contractions	Characteristics
Prodromal stage	Varies	Varies	N/A	Bloody show (mucus mixed with blood) expelled from the vagina
First stage	8–12 h	6–8 h	5- to 15-min intervals	Labor pains and contraction of the uterus begin. Pain may radiate into the small of the back. Amniotic sac often ruptures toward the end of this stage, signified by a gush of fluid from the vagina. This stage lasts until the cervix is fully dilated.
Second stage	1–2 h	30 min	2–3 min apart	Begins as the baby's head enters the birth canal. Woman's pulse rate increases; sweat appears on her face. Cervix becomes fully dilated and effaced. Crowning occurs (presenting part of baby becomes visible). Delivery is imminent. This stage concludes when the baby is fully delivered.
Third stage	5–60 min	5–60 min	N/A	Placental stage. Lasts from delivery of the baby until the placenta has been delivered and the uterus has contracted. Uterine contraction is necessary to squeeze shut all of the tiny blood vessels left exposed when the placenta separates from the uterine wall.

© Jones & Bartlett Learning.

Description

Transition of Fetal Circulation at Birth

Prior to birth, the fetus receives oxygenated blood from the pregnant woman via the umbilical vein, which flows into the ductus venosus and then the inferior vena cava of the fetus, which ultimately leads to the right atrium of the fetus. The fetal lung is collapsed and filled with fluid. The resistance to flow is high, and most of the fetal blood flow is diverted away from the lungs. Blood also goes from the right side of the heart to the left side of the heart through the **foramen ovale**. Additionally, some of the blood flowing into the pulmonary artery is diverted away from the lungs into the aorta via the ductus arteriosus.

As the baby is delivered, the fetal transition occurs; this process enables the baby to breathe. During the fetal transition, the newborn’s lungs must expand with air within seconds. As the baby’s lungs become filled with air, the pulmonary vascular resistance decreases and systemic vascular resistance increases. Blood begins to flow to the lungs, picking up oxygen there. The change in pulmonary pressure then results in closing of the foramen ovale.

This transition can be compromised by poor respiratory effort, airway obstruction, impaired lung function, persistent pulmonary hypertension, cardiac anomalies, and prematurity. During this period, neonates may require ventilatory support to prevent hypoxia, brain injury, or even death. This is a critical time, and timely intervention is essential.

Preterm Labor

Preterm labor, defined as the onset of labor between 20 and 37 weeks’ gestation, is the leading cause of neonatal mortality in the United States. The use of tocolytics (medications to stop contractions) is one of the treatments for preterm labor. These medications are recommended for short-term use to allow for administration of corticosteroids and magnesium sulfate and for transport. The medications indicated for this purpose include beta adrenergic receptor agonists (terbutaline), calcium channel blockers, and NSAIDs.

One of the most important interventions to reduce neonatal morbidity and mortality from preterm labor is the administration of corticosteroids. Both betamethasone and dexamethasone are used for this purpose; they are indicated for use between 23 and 34 weeks' gestation in pregnancies at risk for delivery. The use of these medications can reduce the risk of neonatal respiratory distress syndrome, intracranial hemorrhage, necrotizing enterocolitis, and death. Some evidence also supports the use of corticosteroids up to 37 weeks' gestation to reduce newborn respiratory morbidity.

Magnesium sulfate, once thought to be a tocolytic medication, is no longer recommended to treat preterm labor. However, it is recommended for neuroprotection in preterm labor at less than 32 weeks. The treatment has been shown to decrease the risk of cerebral palsy in infants less than 32 weeks' gestation.

Knowledgeable CCTPs provide a critical link between the local hospital and the tertiary care facility. Careful patient monitoring, readiness to manage changes in the patient's condition while in transit, and a smooth transfer of care to the receiving hospital can all improve patient outcomes. Bed rest and limiting physical activity are no longer routinely recommended to extend gestation. IV hydration, once considered beneficial, has not demonstrated the ability to improve outcomes, either.

Magnesium Sulfate

In the context of childbirth, magnesium sulfate is primarily indicated for fetal neuroprotection. While it does have tocolytic properties, this agent is no longer recommended to treat preterm labor. It is usually administered as a 4- to 6-g bolus, followed by a continuous infusion at 2 to 4 g/h. The mechanism by which magnesium inhibits uterine contraction is not completely clear, but it appears to assert its effects through the antagonism of calcium in muscle cells. The doses required to achieve this effect are close to toxic. Symptoms of magnesium toxicity include decreased reflexes and, ultimately, respiratory depression and respiratory arrest. In a patient receiving magnesium sulfate, the patellar reflexes should be monitored frequently, urine output should be at least 25 mL/h, and there should be no signs of respiratory depression. If any signs or symptoms of toxicity are noted, stop the infusion and contact medical control for further instruction.

Therapeutic levels of magnesium are between 4 and 7 mEq/L. Patellar reflexes become diminished when magnesium levels reach 8 to 10 mEq/L, and respiratory depression and failure occur when they rise above 12 mEq/L. If the patient exhibits a toxic reaction, such as respiratory depression, stop the infusion, give 1 g of calcium gluconate by *slow* IV push, and administer oxygen to maintain an oxygen saturation of greater than 90%. If the patient experiences respiratory failure, intubation is necessary.

Precipitous delivery, which is delivery in less than 3 hours from the onset of regular contractions, may occur with premature labor. On presentation, inquire about the frequency and duration of contractions. Ask about any vaginal leakage of blood, fluid, or mucus. **Premature prelabor rupture of membranes (PPROM)** is the rupture of membranes before the onset of labor in a gestation of less than 37 weeks. PPROM accounts for as many as 30% of all preterm deliveries. Most women will deliver within 7 days of rupture of membranes. There is an increased risk of infection with PPROM, so antibiotics are routinely administered to patients with this condition. All prehospital deliveries are considered emergencies and, by definition, are high risk. The best way to reduce risk is to be prepared.

Tocolytics (Terbutaline, Nifedipine, and Indomethacin)

Tocolytics are only marginally effective in stopping preterm labor. Terbutaline is a beta-2 agonist that, when used in sufficient doses, can successfully reduce uterine contractions. The doses used to produce this effect, however, can result in side effects by stimulating beta-2 receptors elsewhere, such as in the myocardium. Stimulation of myocardial receptors can result in tachycardia or frank myocardial ischemia in patients with underlying coronary artery disease. Thus, the patient should have continuous cardiac and fetal monitoring during transport and be frequently assessed for signs and symptoms of myocardial ischemia, such as chest pain or pulmonary edema. Terbutaline should not be administered if the maternal pulse exceeds 140 beats/min.

The effects of beta-2 stimulation of the pancreas can result in hyperglycemia, which can be monitored in the pregnant patient using finger-stick glucose checks. If the baby is delivered during transport, the baby should be checked for hypoglycemia. Fetal hypoglycemia occurs secondary to the need for increased insulin production by the fetus to compensate for high maternal glucose levels. Other, less significant side effects of terbutaline treatment may include maternal headache, tremor, vomiting, fever, and hallucinations.

Nifedipine may be the most effective tocolytic. It is typically administered as a 10- to 30-mg loading dose orally or sublingually every 15 to 20 minutes for the first hour, followed by 10 to 20 mg orally every 4 to 8 hours thereafter. Side effects are usually mild and related to peripheral vasodilation. Hypotension is more often seen with sublingual than oral administration and is typically limited to the initial few hours of dosing.

Indomethacin, an NSAID, can be used before 32 weeks' gestation as a tocolytic. It is not used beyond this point in gestation because it may cause premature closure of the ductus arteriosus, which can be catastrophic. This medication is typically used for only 72 hours, as it may cause oligohydramnios (low amniotic fluid). Indomethacin is started as a loading dose of 50 to 100 mg, followed by 25 mg every 4 to 6 hours.

Prolonged Pregnancy

Prolonged pregnancy (past 40 weeks' gestation) can lead to instances of fetal hypoxia during labor, a higher percentage of meconium production, and a low amniotic fluid index. CCTPs need to be aware of these risks and have meconium suctioning equipment available prior to delivery **FIGURE 22-13**.

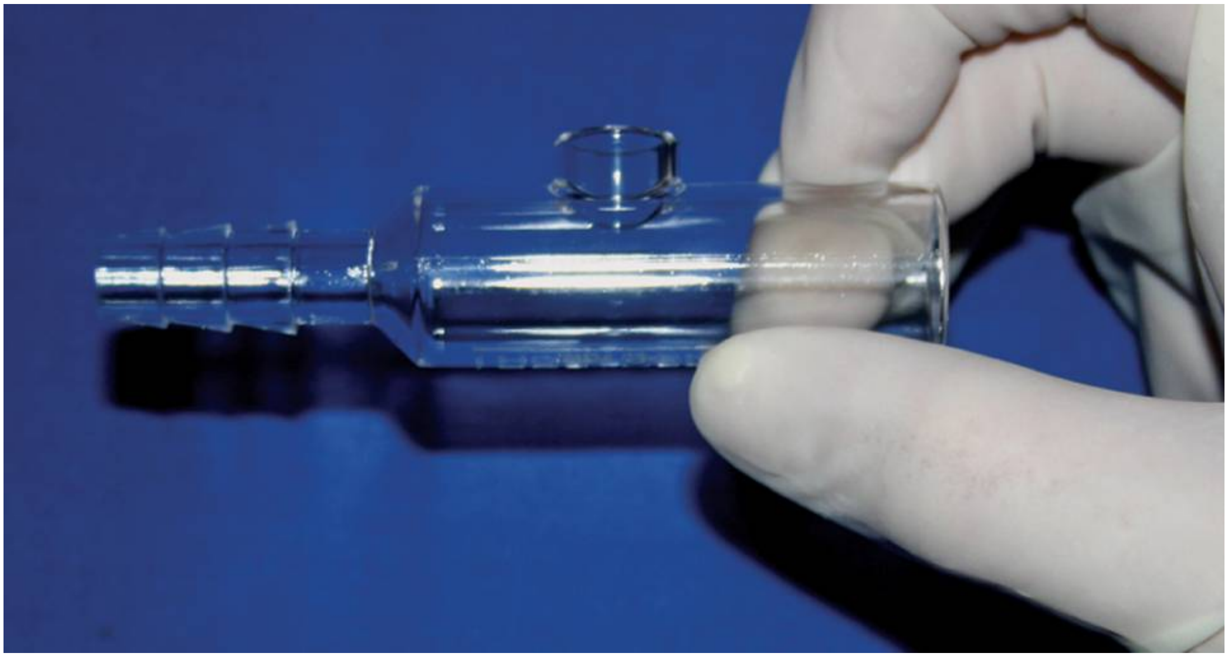


FIGURE 22-13 A meconium aspirator.

Meconium aspirator courtesy of Neotech Products, Inc.

Signs and Symptoms

Preterm Labor

Prior to 37 weeks' gestation:

- Rhythmic uterine contractions
- Cervical dilation
- Rupture of membranes
- Passage of blood-stained mucus

Differential Diagnosis

Preterm Labor

- Abruptio placentae
- Ectopic pregnancy
- Placenta previa
- Early pregnancy loss

Transport Management

Preterm Labor

- Provide or continue glucocorticoids to promote lung maturity.
- Continue antibiotics if the patient has PPROM.
- Consider administration of tocolytic agents.

Delivery

Vertex, or head-first presentation, is the ideal and most common presentation for all deliveries; crowning is observed as the second stage of labor begins. It is the CCTP's responsibility to note unexpected events and to manage them to minimize maternal and fetal mortality and morbidity.

Normal crowning and normal shoulder presentation are shown in **FIGURE 22-14** and **FIGURE 22-15**, respectively.

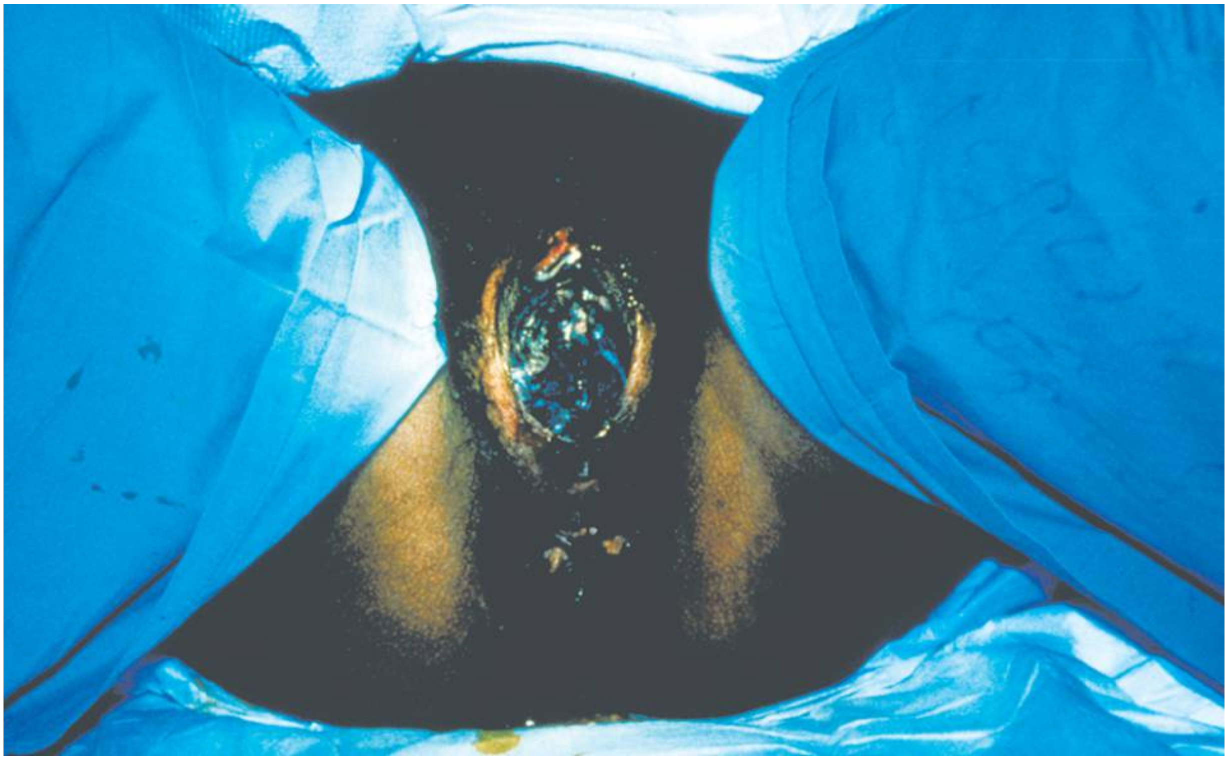

FIGURE 22-14 Normal crowning.

© American Academy of Orthopaedic Surgeons.

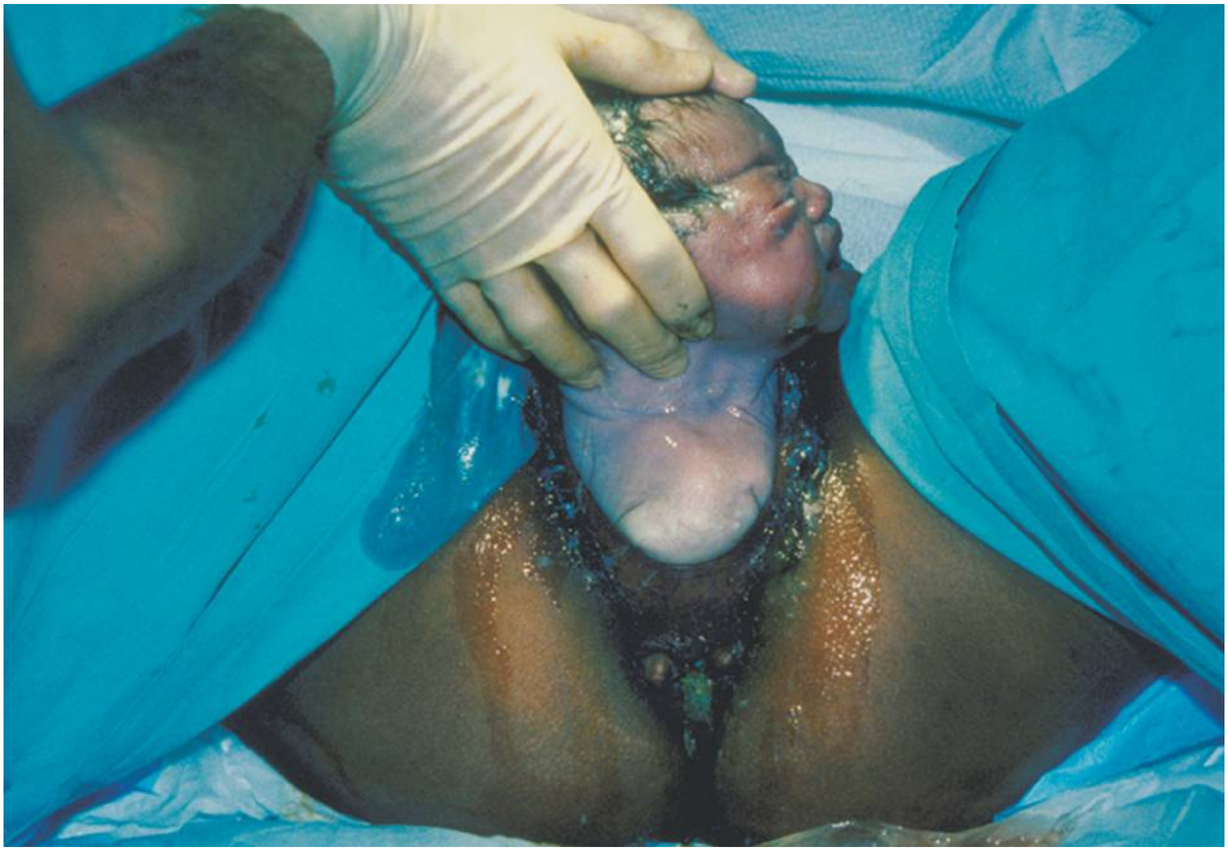

FIGURE 22-15 Normal shoulder presentation.

© American Academy of Orthopaedic Surgeons.

Malpresentations

Breech presentation is the most common malpresentation, occurring in 4% of all deliveries. This presentation is associated with an increased risk of asphyxia and fetal mortality, though one-third of these deaths are considered preventable. Breech presentations are more common with premature infants and low-birth-weight infants, although two-thirds of breech infants weigh more than 5.5 lb (2,500 g).

There are four common variants of breech presentation:

- **Frank breech**: Both of the infant's hips are flexed and the feet are near the infant's head **FIGURE 22-16**.
- **Complete breech**: The hips are flexed and the legs are flexed at the knees and oriented transversely to the birth canal; the

buttocks present with the legs flexed and the feet along the buttocks **FIGURE 22-17**.

- **Incomplete breech**: Similar to complete breech except one foot extends into the birth canal **FIGURE 22-18**.
- **Footling breech**: Both feet extend into the birth canal **FIGURE 22-19**.

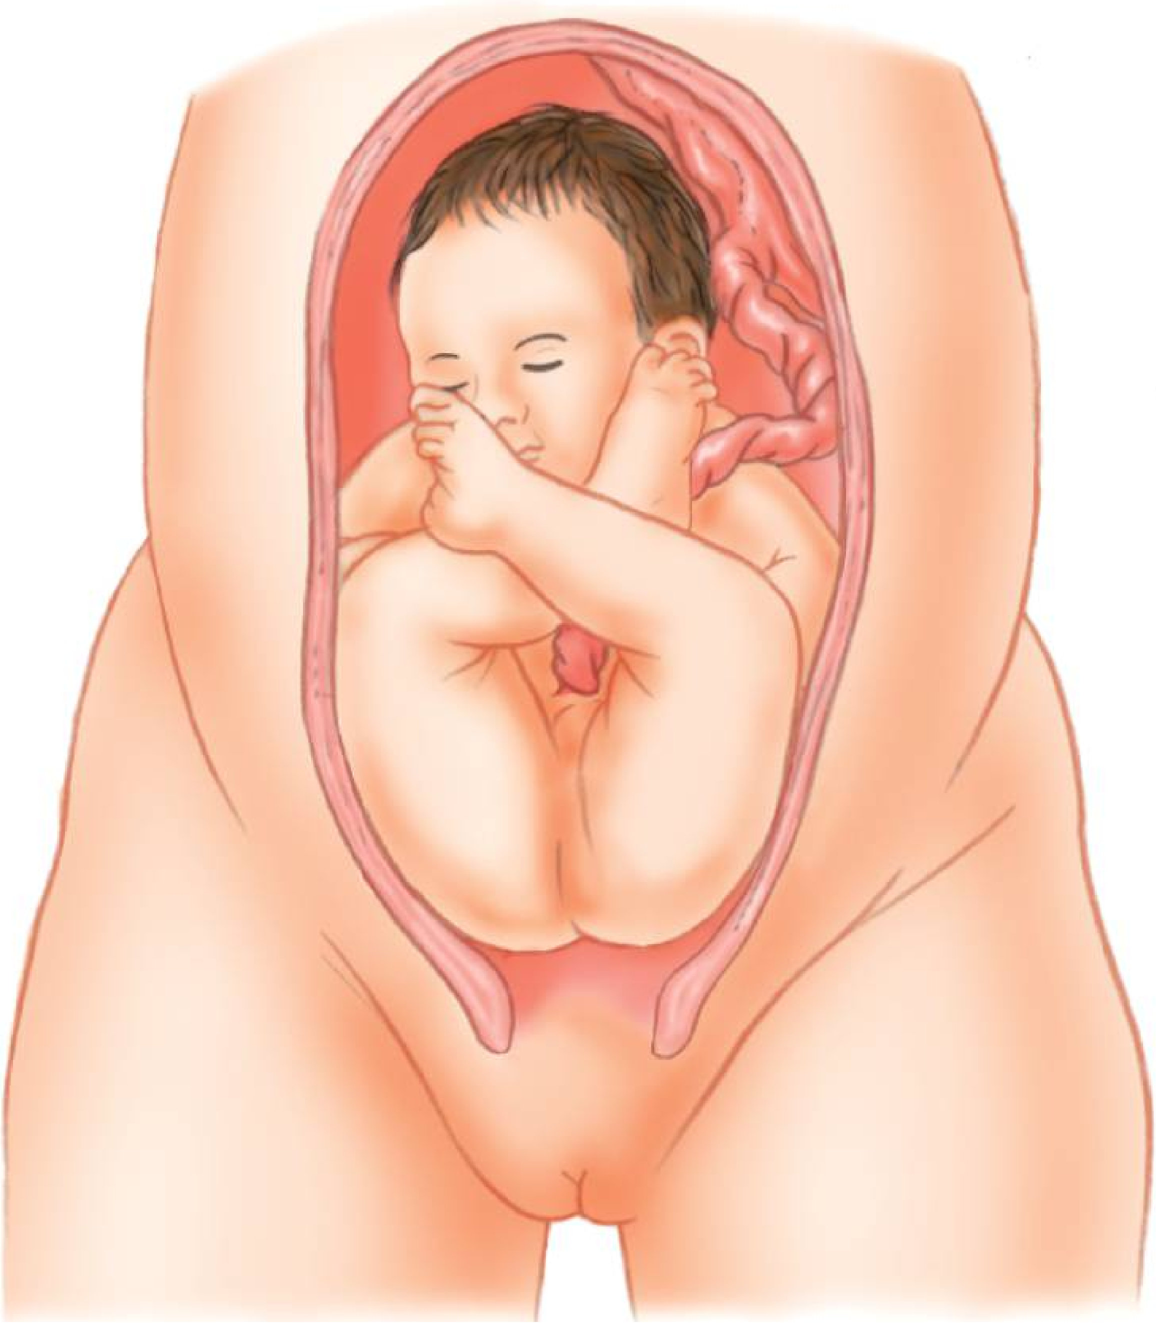

FIGURE 22-16 Frank breech presentation.

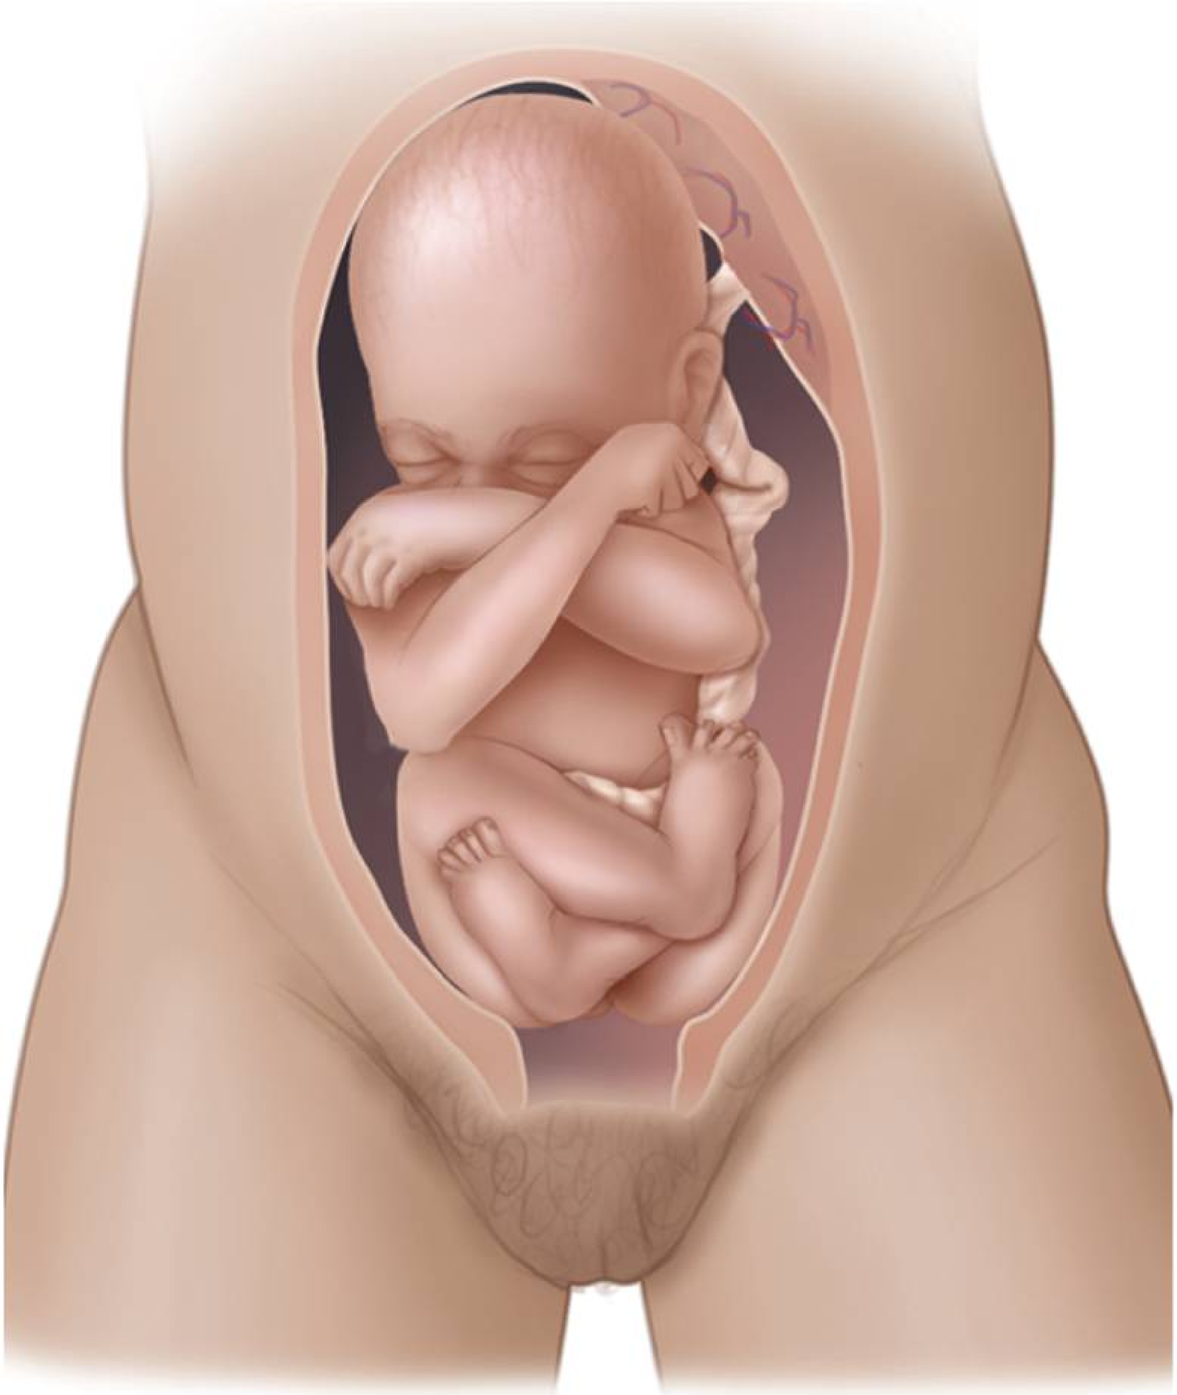

FIGURE 22-17 Complete breech presentation.

© Jones & Bartlett Learning.

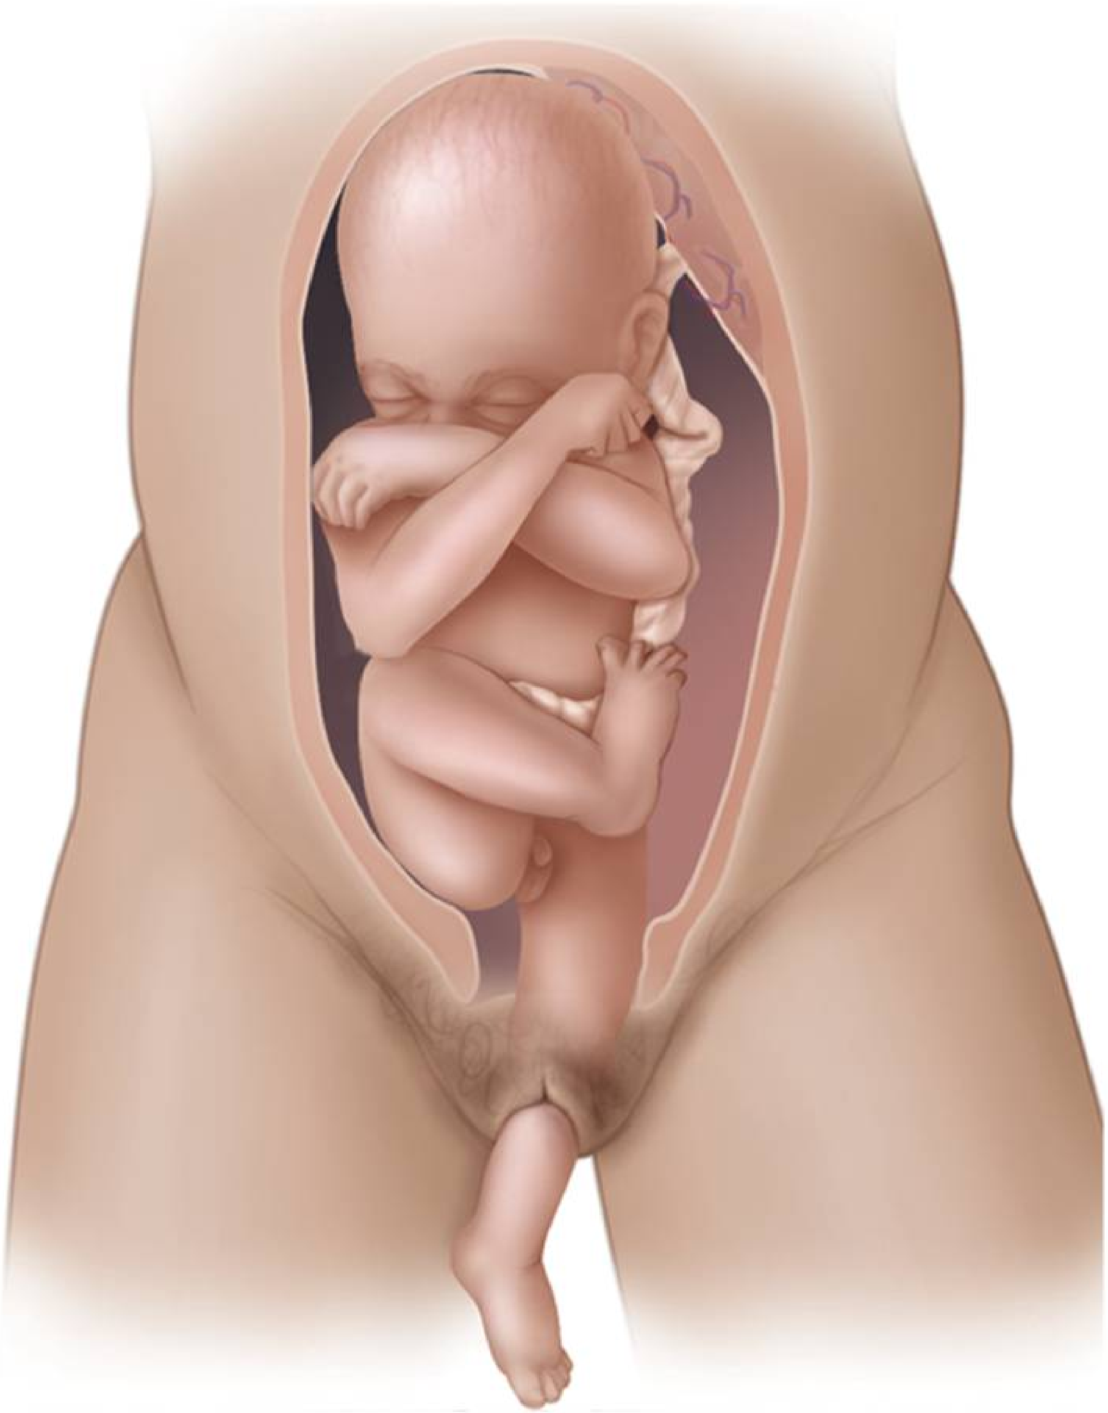

FIGURE 22-18 Incomplete breech presentation.

© Jones & Bartlett Learning.

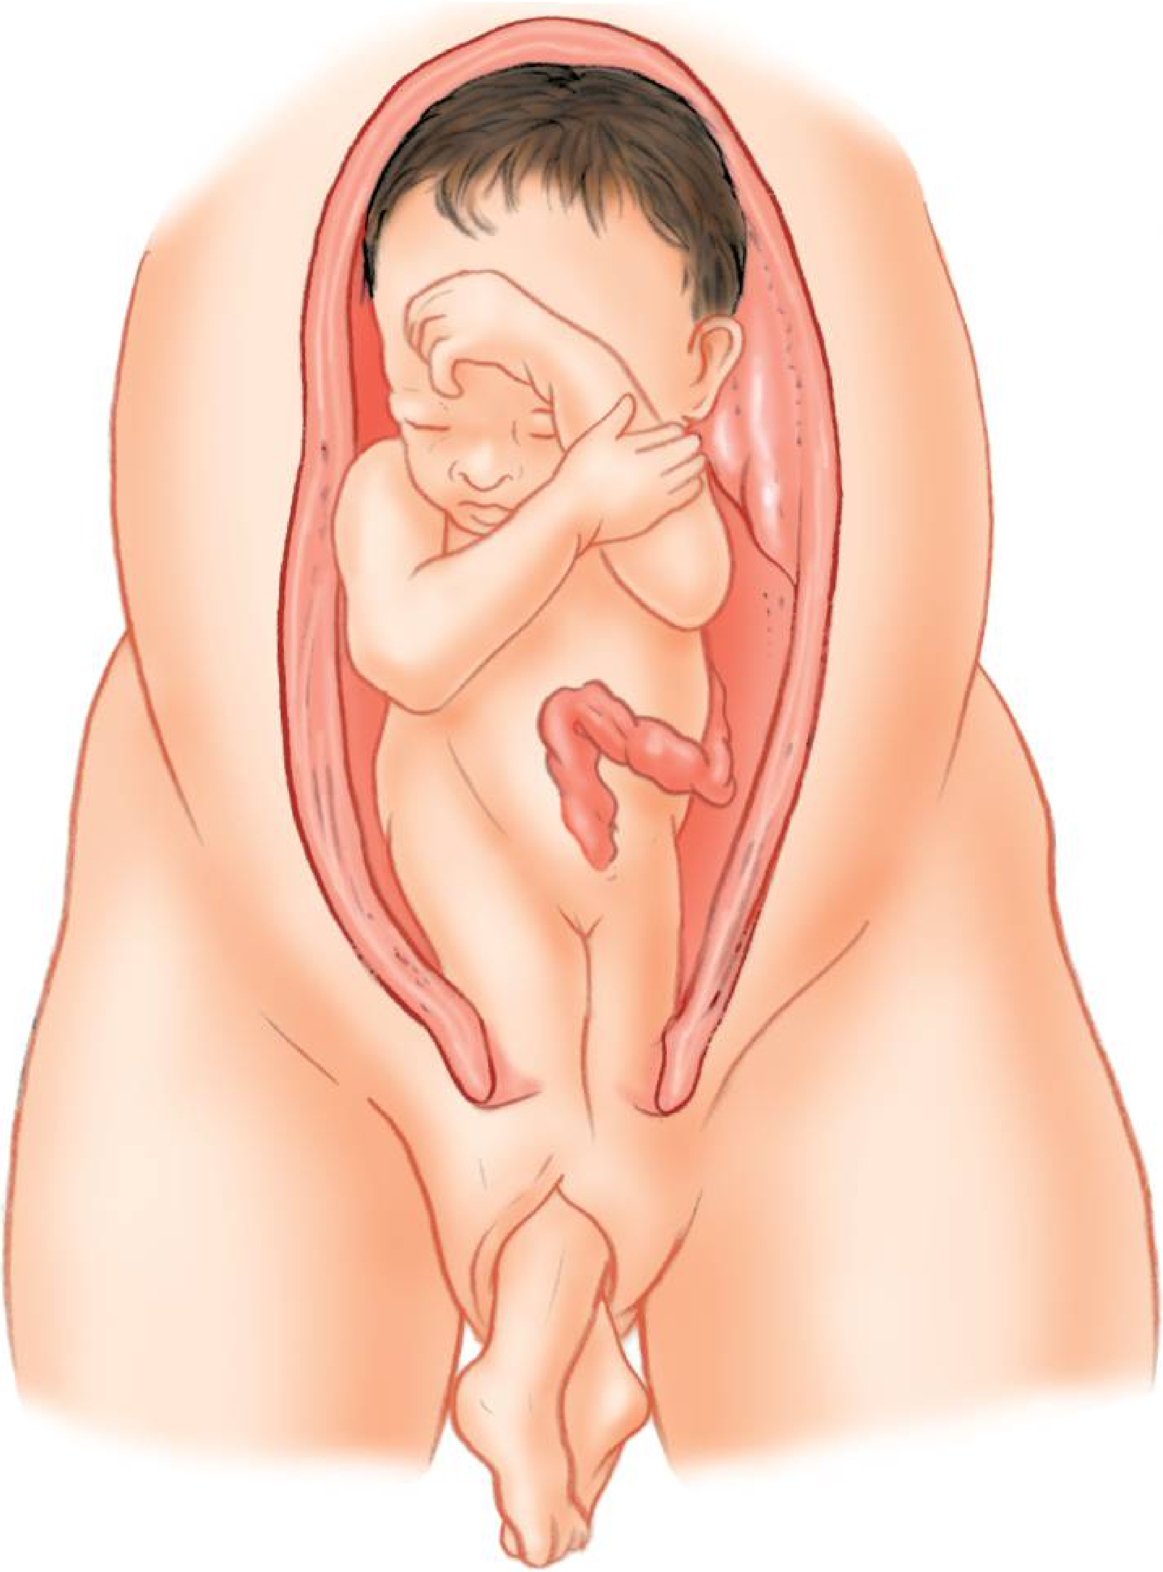

FIGURE 22-19 Footling breech presentation.

© Jones & Bartlett Learning.

In a normal vertex delivery, the head presents first and dilates the cervix. The largest part of an infant is the head, so the rest of the body usually delivers without difficulty. This is not the case in a breech delivery. In a frank breech or complete breech, the hips, thighs, and buttocks are thought to adequately dilate the cervix and vaginal delivery can be accomplished. In an incomplete or footling breech presentation, a foot can slip through an incompletely dilated cervix, but the rest of the fetus will not deliver. Therefore, fetuses presenting in the incomplete or footling breech positions must be delivered via cesarean section. The CCTP’s role in these situations is to provide safe and swift transport to facilities that can accomplish this delivery. External inspection for cord prolapse should also occur.

When delivering an infant in the frank or complete breech position, the overarching message is *do not apply traction to the fetus*. Applying traction to the fetus increases the risk of head entrapment and injury to the fetus. The delivery is accomplished with maternal expulsion effort alone. Once the fetus has delivered to the level of the umbilicus, the CCTP may begin to assist. If the legs have not delivered, apply gentle pressure to the posterior aspect of the fetal knee, flexing the leg and sweeping it across the trunk, then inferiorly to an extended position.

Once the legs are delivered, wrap the buttocks in a towel. At this time the patient can push with contractions. The arms may deliver spontaneously. If the arms do not deliver spontaneously, the CCTP may assist once the fetus has been expelled to the level of the scapula. Rotate the fetus so that one shoulder is at the 12 o’clock position. Next, reach into the vagina and identify the elbow. Sweep the arm across the fetal trunk and deliver it. To deliver the second arm, rotate the fetal trunk so that the opposite shoulder is in the 12 o’clock position, and execute the same maneuver to deliver the arm.

Once both arms are delivered, rotate the trunk so that the fetal sacrum is anterior (buttocks toward the sky). Using one arm to support the now visible body, insert the second hand into the vagina. Identify the face, and place one finger in either side of the nose. Apply gentle pressure to cause flexion of the fetal head. This flexion is key to averting head entrapment. It can be enhanced by a second responder applying fundal pressure. Lastly, deliver the head in an upward arc, in contrast to a vertex delivery where the primary motion is downward. This upward movement follows the shape of the maternal sacrum.

Umbilical Cord Prolapse

Occasionally, the presenting part may be the umbilical cord **FIGURE 22-20**. This condition, in which the umbilical cord passes through the birth canal in advance of the infant, is known as a **prolapsed cord** and can have serious consequences for the infant. It is most likely to occur in preterm and breech deliveries.

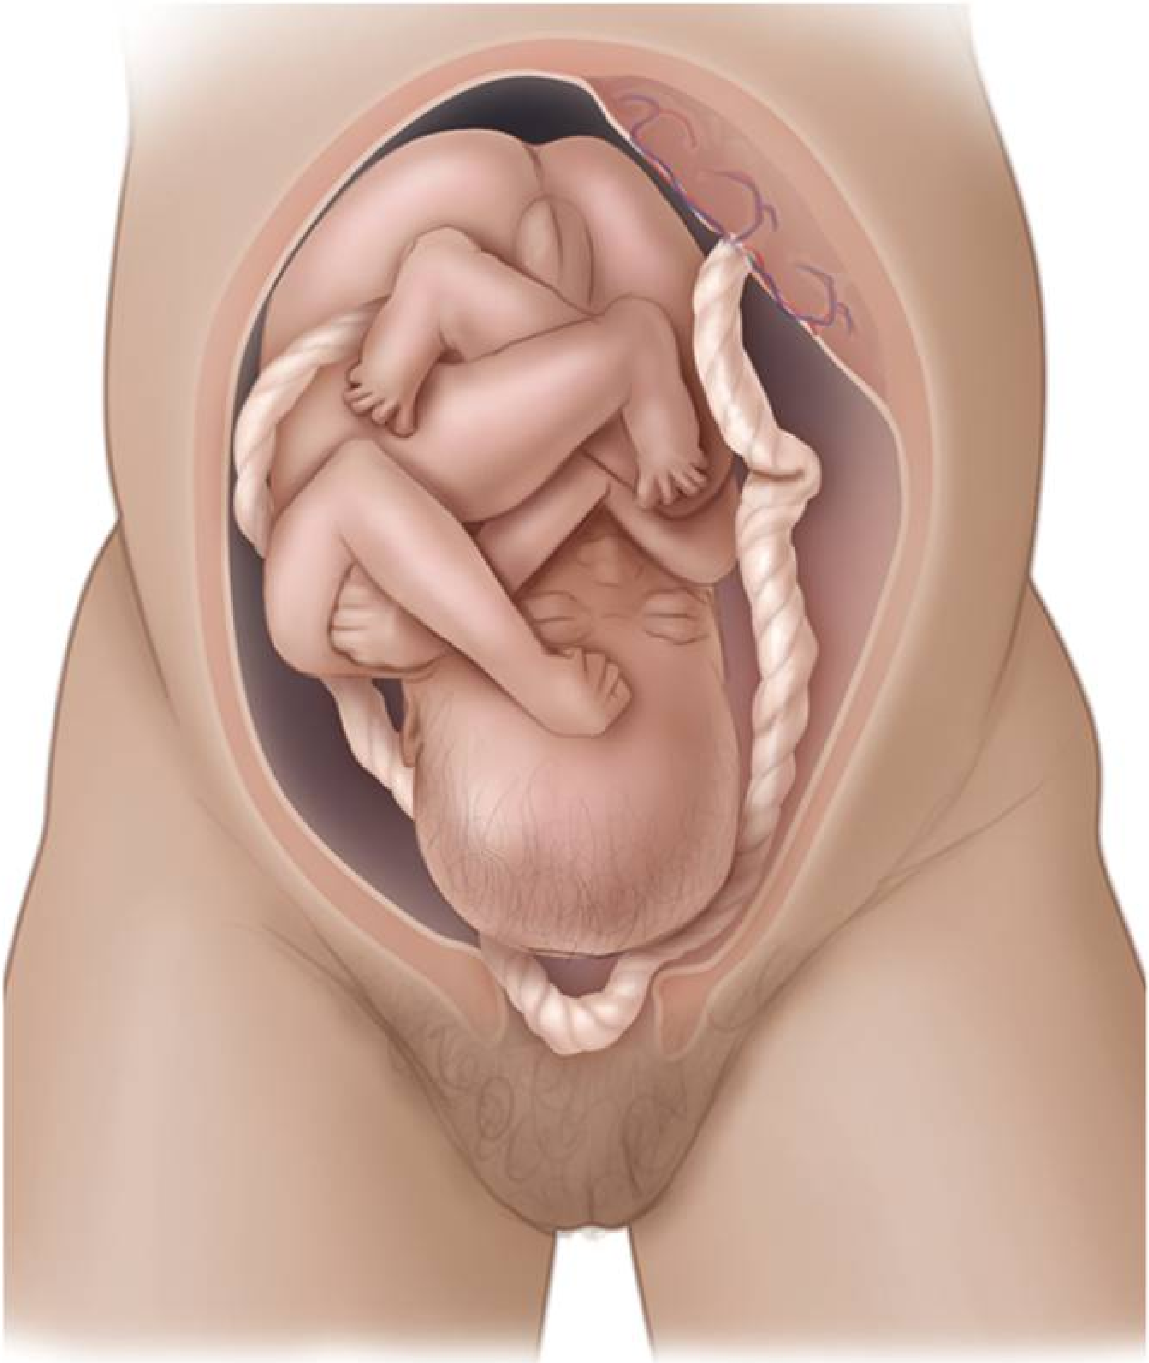

FIGURE 22-20 A prolapsed cord.

© Jones & Bartlett Learning.

The cord may be compressed between the bony pelvis of the mother and the head of the infant, thereby decreasing blood flow to the infant. This may result in fetal hypoxia.

In the event of a prolapsed cord, place the patient on 100% oxygen by nonrebreathing mask and place her in the knee-chest position on the stretcher. In this position, the patient is facedown on her elbows and knees with buttocks elevated **FIGURE 22-21**. If the patient cannot tolerate this position, an alternative is the Trendelenburg position. Once the patient is positioned correctly, encourage her not to push. Insert two gloved fingers into the vagina to gently elevate the presenting part to relieve pressure on the cord. *Do not push the cord back into the cervix.* Minimize manipulation of the cord to reduce the risk of vasospasm. Continue rapid transport and notify the receiving hospital as soon as possible.

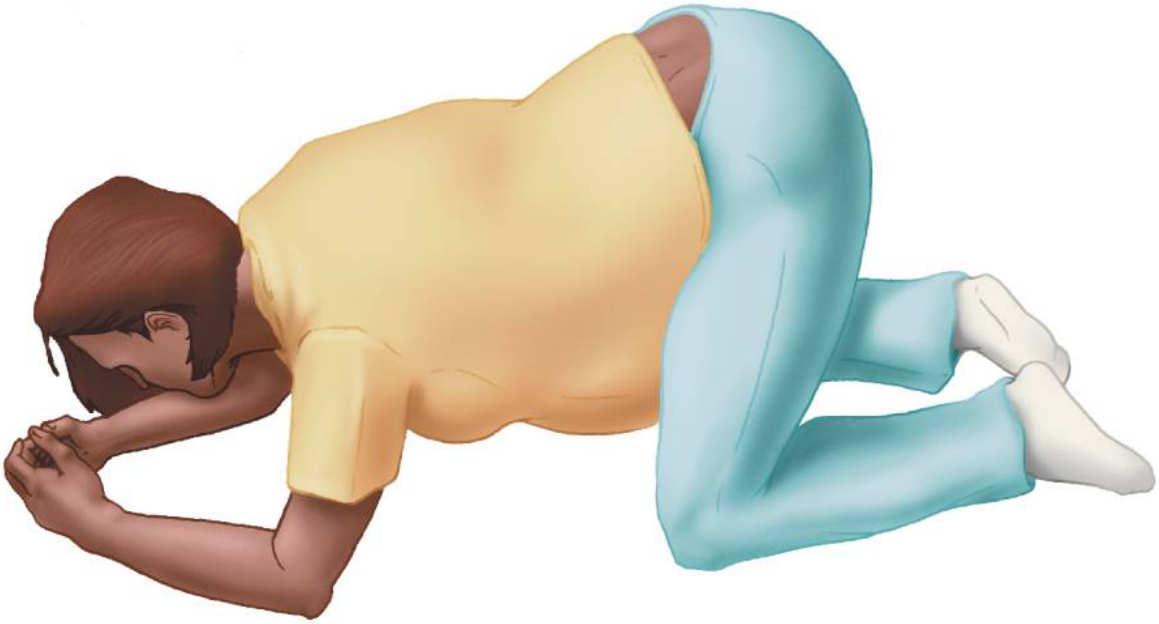

FIGURE 22-21 The knee-chest position should be used in the event of a prolapsed cord.

© Jones & Bartlett Learning.

Transport Management

Umbilical Cord Prolapse

- Administer oxygen.

- Position the patient in either the knee-chest position or the Trendelenburg position.
- Insert two gloved fingers to elevate the presenting part.
- Encourage the patient not to push.
- Avoid manipulation of the cord.
- Provide rapid transport.

Shoulder Dystocia

Shoulder dystocia occurs in approximately 1 of every 100 vertex deliveries. This condition can be recognized from the “turtle sign”: The fetal head will begin to protrude and then withdraw back inside because the shoulders are too large to exit the pelvis. This is a true obstetric emergency, and recognition is key to a good outcome. CCTPs must assist the mother with the next contraction. The first intervention is to perform the McRoberts maneuver. Have the patient flex her legs against her abdomen (**FIGURE 22-22**). This maneuver increases the functional size of the pelvis. With the next contraction, have the patient push. This will successfully reduce the dystocia in approximately 40% of cases. Adding suprapubic pressure will further increase the rate of success. Apply direct pressure just above the pubic symphysis to move the anterior shoulder of the infant underneath the pubic bone. Do not apply fundal pressure, however; doing so will further impact the shoulder against the pubic bone.

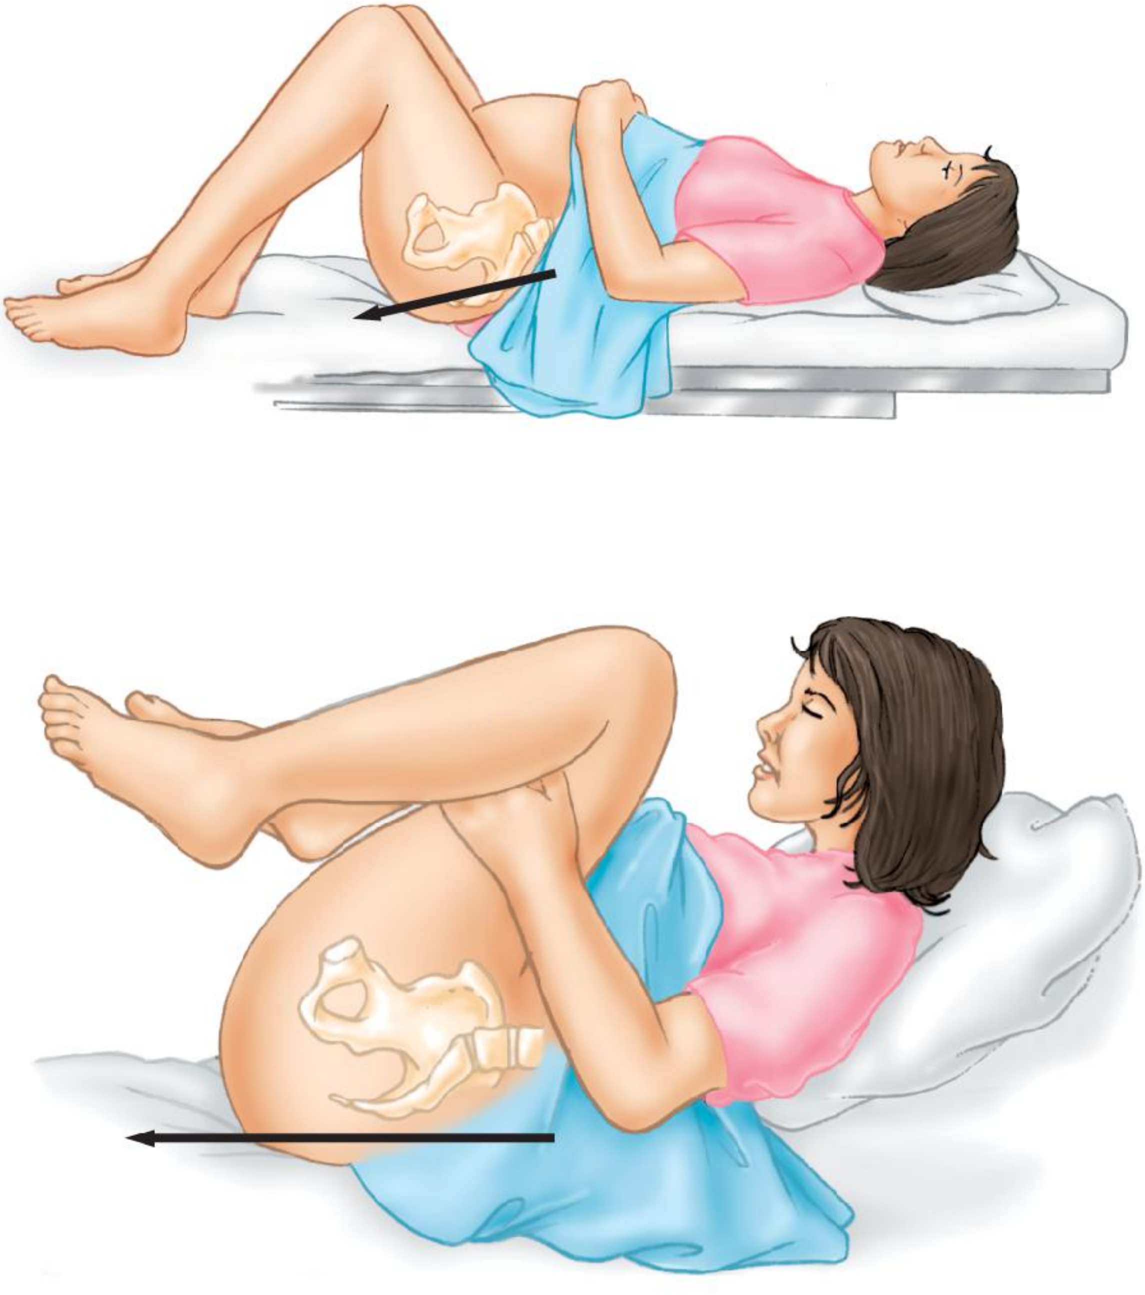

FIGURE 22-22 If the fetal head begins to protrude and then withdraws back inside (a sign of shoulder dystocia), the first step is to have the mother flex her legs to her abdomen to help enlarge the birth canal.

© Jones & Bartlett Learning.

Additional maneuvers may be required if the preceding approaches are not successful. The next maneuver is delivery of the posterior arm. (Remember to stop the suprapubic pressure during this maneuver.) Insert a gloved hand underneath the infant. Identify the humerus and sweep it across the trunk and ultimately the face. This will create more room for the anterior shoulder to slide under the pubic bone. Rotational maneuvers can also be employed if the dystocia persists. For example, the CCTP can apply pressure to either shoulder and attempt to turn the baby within the birth canal. Additionally, the Gaskin maneuver can be used. In this maneuver, the mother is placed on all fours, with hands and knees on a flat surface. The thought is that gravity will assist in the delivery.

It is imperative to not apply excessive traction on the fetal head during the delivery effort. Infants can experience fractures and brachial plexus injuries from excessive force. Timing is also crucial. Often there is compromised blood flow and thus compromised oxygenation of the fetus during a shoulder dystocia. If possible, keep a timetable of events. If the attempts to reduce the dystocia are unsuccessful, obstetricians can perform a Zavanelli maneuver. In this procedure, the head is pushed back into the birth canal and a cesarean section is performed.

CCTPs have varying scopes of practice, depending on their experience, training, and local protocols. All of these factors need to be taken into consideration when managing a complicated shoulder dystocia. In some instances, the best course of action may be to simply get to the nearest facility that can manage this complication.

Signs and Symptoms

Shoulder Dystocia

- “Turtle sign”—the infant’s head protruding and withdrawing into the birth canal

Transport Management

Shoulder Dystocia

- Perform the McRoberts maneuver.
- Apply suprapubic pressure.
- Consider delivery of the posterior arm.
- Provide rapid transport.

Multiple Births

Single gestations are most common, but many CCTPs will encounter a multiple-gestation pregnancy and potential delivery. The incidence of twin gestation is 1 in 100 births; that of triplets is 1 in 10,000 births. The presence of a multiple-gestation pregnancy should be identified through the history obtained from the patient. Twins may share a placenta and a gestational sac, or each may have its own individual sac and placenta. Twins that share a sac should not deliver vaginally. Instead, they must be delivered by cesarean section to avoid cord accidents; umbilical cords of the two fetuses could become entangled and cut off their circulation.

The presentation of the twins is important. The first twin needs to be in a vertex presentation to allow for a safe delivery. There is a theoretical risk of interlocking chins if the first twin is breech and the second twin is vertex (**FIGURE 22-23**).

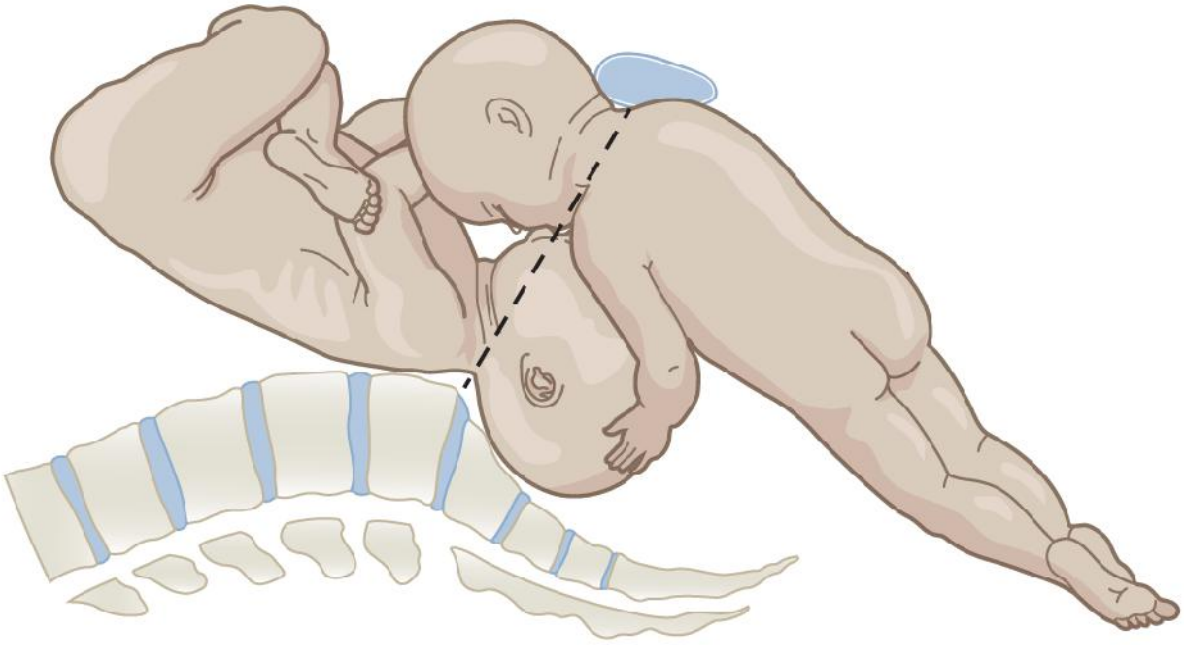

FIGURE 22-23 When assisting in the delivery of twins, be aware of the infants' presentation. Their chins may become interlocked if the first twin is breech and the second twin is vertex.

© Jones & Bartlett Learning.

After the first infant is delivered, double-clamp that infant's cord to prevent bleeding (in the case of a shared placenta) and allow for identification of each infant's cord. Place one clamp several inches from the infant's abdominal wall and a second clamp several centimeters away from the first. Divide the cord between the two clamps. If the second twin delivers, repeat the process, but use two clamps at each site to identify this as the second twin's cord **FIGURE 22-24**.

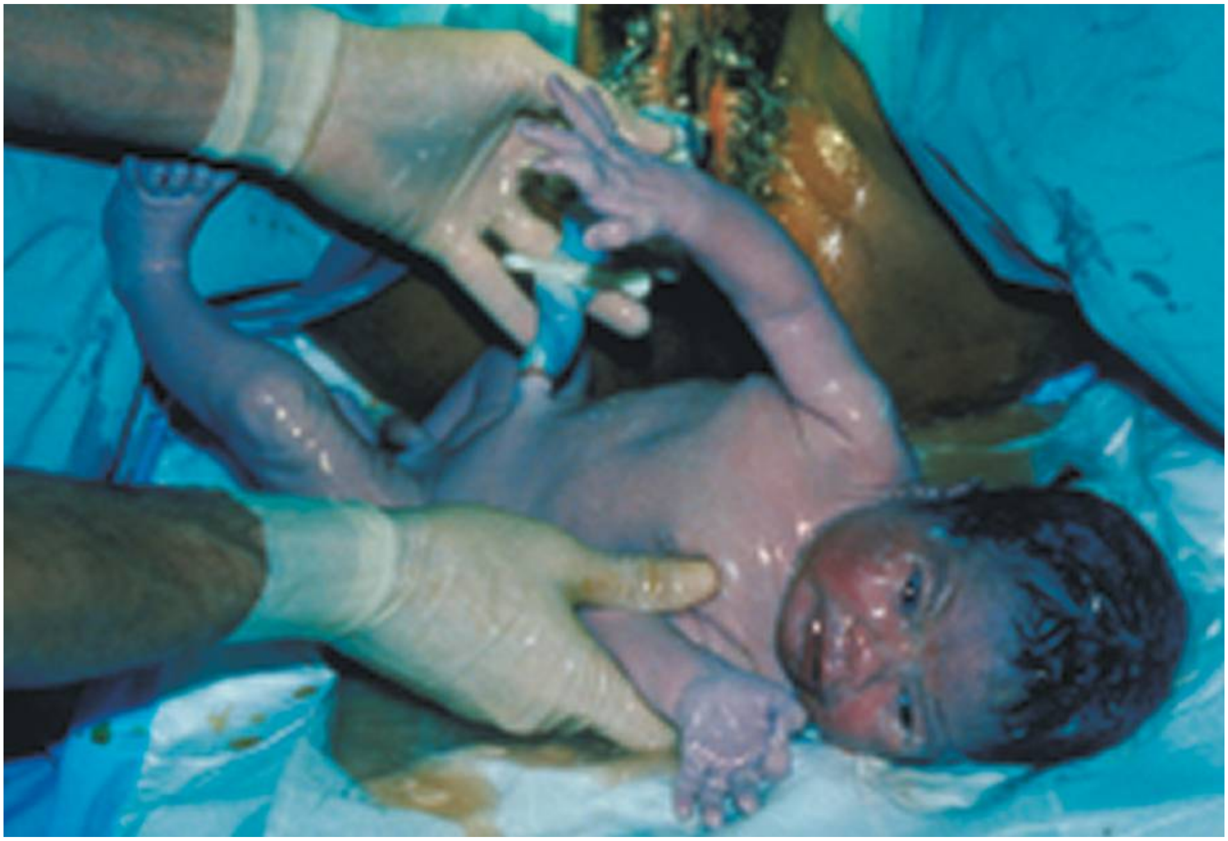

FIGURE 22-24 Tie or clamp the cord in two places. Cut the cord between the two ties or clamps.

© American Academy of Orthopaedic Surgeons.

The timing of delivery for the second twin is highly variable. During this interval, transport should continue and should be interrupted only if the next infant begins to emerge from the birth canal. Malpresentation is common in the second twin. A breech presentation, and even a footling or incomplete breech, can be delivered vaginally because the cervix has already been completely dilated by the first twin. Watch for transverse lie and cord prolapse in the second twin.

Do not attempt to deliver the placenta of the first twin before delivery of the second twin. Placentas can be fused, and an attempt to deliver the first infant's placenta can disrupt the placenta of the second twin.

Delivery of the Placenta

Delivery of the placenta defines the third stage of labor. Active management of this process has been shown to reduce the risk of postpartum hemorrhage. Active management consists of administration of oxytocin 20 to 40 units in 1 L IV saline solution over 20 to 40 minutes. *Do not give oxytocin via IV push; doing so can cause profound hypotension.* The second action is to apply gentle traction to the umbilical cord. The third action is to perform fundal massage. The CCTP will be able to identify when the placenta is beginning to separate from the uterine wall by a small gush of blood and a lengthening of the umbilical cord. The patient may assist the delivery of the placenta with a push.

Postdelivery Care

Once delivery is complete, care for both the mother and the infant should continue. Determine the newborn's ABCs and Apgar score (further discussed in Chapter 23, *Neonatal Emergencies*). Examine the mother's perineum for tears. Place a large absorbent pad (to determine pad count) under the mother at the perineum. If large tears are actively bleeding, apply direct pressure. Significant postpartum hemorrhage is defined as greater than 500 mL of blood loss within 24 hours after delivery of the infant. In general, a saturated sanitary pad contains 100 mL of blood; a soiled pad is estimated to contain 30 mL. Often the source of bleeding is not easy to identify, so massage the uterus and establish one or two large-bore IV lines with a crystalloid solution running open. Administer high-flow oxygen as well.

The infant should be thoroughly dried, wrapped in warm blankets, and placed on the mother's chest with skin-to-skin contact if possible. Umbilical cord clamping should be delayed 30 to 60 seconds when the infant is vigorous. If the infant is depressed, resuscitate as indicated. The Apgar score should be obtained at 1 and 5 minutes after delivery. If the Apgar score is less than 7, repeat it every 5 minutes. Continue with any supportive measures applied as needed while transporting.

Postdelivery Complications

Postpartum Hemorrhage

Obstetric hemorrhage is the leading cause of maternal mortality worldwide. Prompt recognition and treatment of such hemorrhage, therefore, is important in lowering maternal mortality. Although bleeding is common during delivery, blood loss of more than 500 mL or any volume of blood loss that causes signs of hemodynamic instability is considered serious. Previous cesarean sections, more than four previous vaginal births, low-lying placenta, and magnesium sulfate therapy are all risk factors associated with postpartum hemorrhage. To assess the causes of postpartum hemorrhage, use the four Ts:

- Tone: uterine atony and uterus not contracting, leading to excessive bleeding
- Trauma: lacerations, hematomas, uterine rupture
- Tissue: retained placenta
- Thrombin: coagulopathy

Uterine atony is treated with fundal massage (**FIGURE 22-25**) and uterotonic agents, including oxytocin, methylergonovine, misoprostol, and carboprost. Direct pressure should be applied to lacerations and hematomas until the patient arrives at the definitive care location. Retained tissue is often removed manually by the obstetrician. Coagulopathy is likely to be seen after abruptio placentae or amniotic fluid embolism.

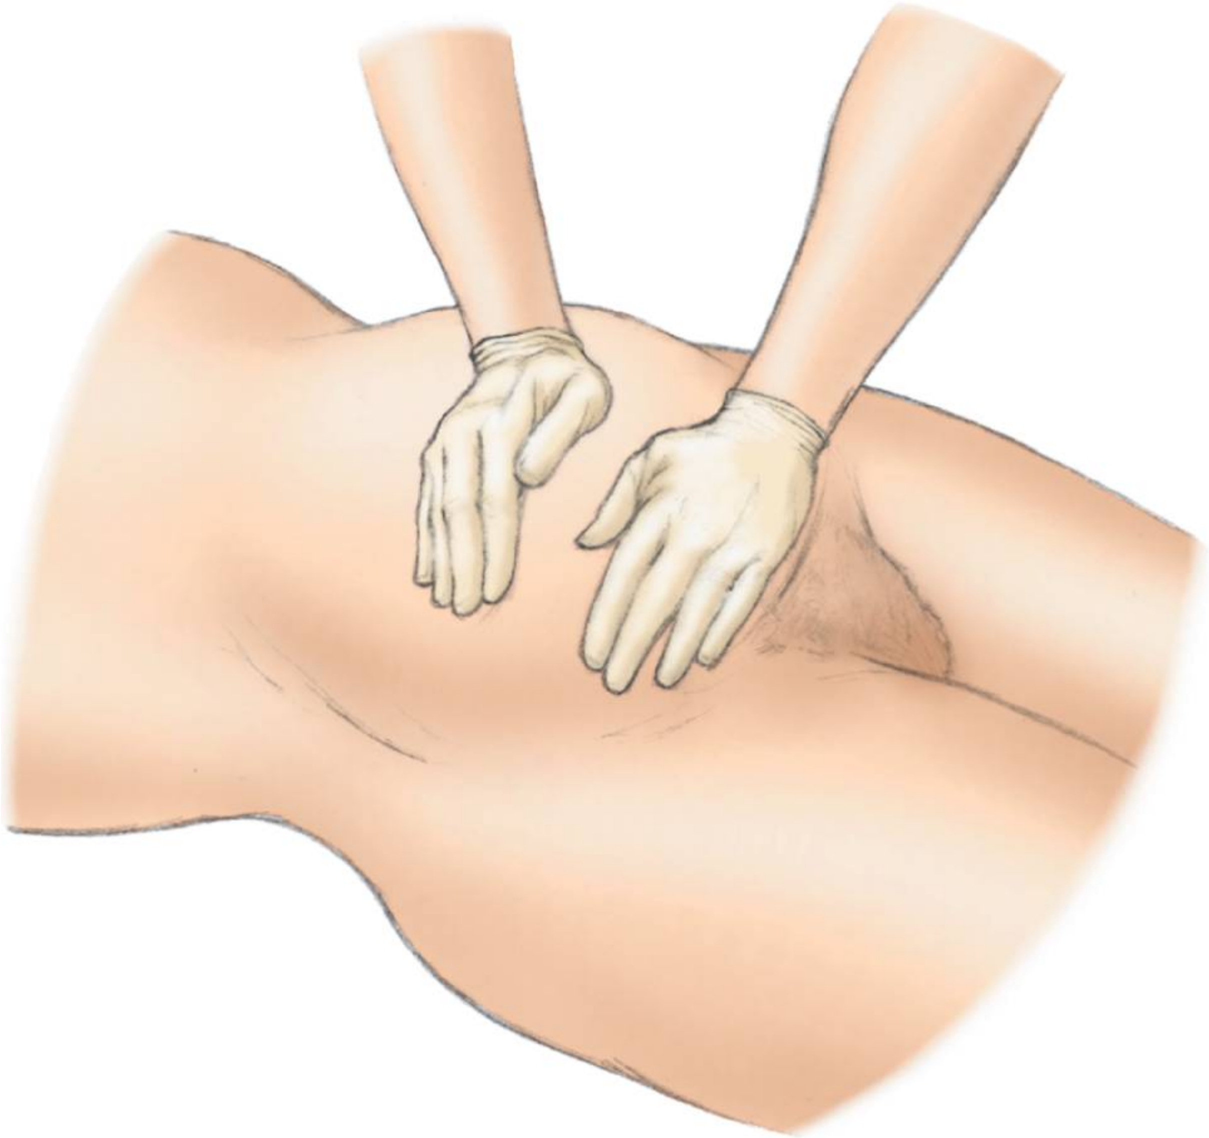

FIGURE 22-25 Fundal massage should be performed with the patient lying supine once the patient has delivered.

© Jones & Bartlett Learning.

Signs and Symptoms

Postpartum Hemorrhage

- Severe bleeding after delivery

Transport Management

Postpartum Hemorrhage

- Place padding to absorb the blood.
- Perform fundal massage.
- Administer oxytocin after the placenta has delivered.

Amniotic Fluid Embolism

Amniotic fluid embolism (AFE) is a rare event, occurring in 2 to 6 of every 100,000 pregnancies. While this condition was historically believed to be a true embolism of amniotic fluid, this theory has fallen out of favor. Whenever the maternal fetal circulation is disrupted, fetal cells enter the maternal circulation. In AFE, an immunologic response, referred to as the anaphylactoid reaction of pregnancy, occurs and the pulmonary vasculature constricts. This vasoconstriction causes right-side heart failure and subsequently left-side heart failure. Ultimately, pulmonary edema and systemic hypotension occur. These patients often go into disseminated intravascular coagulation.

Although AFE usually occurs around the time of delivery, it can happen with any disruption of the maternal-fetal barrier. For example, trauma or efforts to maneuver the fetus in utero can precipitate AFE. Patients may present with all or some of the following symptoms: hypoxia, hypotension, bleeding, shivering or rigors, and even seizure.

AFE carries a significant mortality rate, ranging from 24% to 80% in developed countries. The CCTP must recognize its signs and symptoms early. Care is supportive, as there is no “cure” for AFE. Patients will require airway management, including supplemental oxygen and progressing up to intubation. IV access should be obtained to allow for treatment of hypotension or hemorrhage with crystalloid or blood. These patients require immediate transport.

Signs and Symptoms

Amniotic Fluid Embolism

- Sudden onset of shortness of breath
- Sudden onset of hypotension
- Chest pain
- Restlessness
- Anxiety
- Coughing
- Vomiting
- Pulmonary edema with pink, frothy sputum
- Sense of impending doom
- Shivering or rigors
- Seizures
- Coma
- Sudden death

Transport Management

Amniotic Fluid Embolism

- Administer supplemental oxygen.
- Provide fluid resuscitation.
- Provide rapid transport.
- Administer positive end-expiratory pressure.
- Perform intubation if necessary.
- Administer blood.

Uterine Inversion

Uterine inversion is an obstetric emergency, which can be associated with life-threatening hemorrhage and shock. It occurs when the uterine fundus collapses into the endometrial cavity. This condition usually occurs during the third stage of labor (delivery of the placenta). Care should be taken when delivering the placenta to avoid excessive traction on the umbilical cord before the placenta is separated from the uterine wall. The CCTP should suspect uterine inversion when a smooth round mass protrudes from the **introitus**.

The immediate treatment is replacement, which is beyond the CCTP’s scope of practice. It is imperative to avoid removing the placenta from an inverted uterus, as uncontrollable hemorrhage may ensue. Surgical intervention is often required for uterine replacement.

Transport Management

Uterine Inversion

- Flush the vagina with saline (hydrostatic correction).
- Administer oxytocin.

Gynecologic Emergencies

Pelvic Inflammatory Disease

Pelvic inflammatory disease (PID) is an infection of the female reproductive tract typically caused by a sexually transmitted infection (STI)—namely, gonorrhea or chlamydia. It can occur as a result of delayed antibiotic treatment of an STI, which allows bacteria to travel from the vagina and cervix into the uterus, fallopian tubes, and/or ovaries. Initially, patients with gonorrhea and/or chlamydia may experience vague or no symptoms, or they may experience vaginal discharge, abnormal vaginal bleeding, or vaginal pain. If the patient does not receive adequate treatment with antibiotics, the bacteria may ascend up the reproductive tract. At that point, patients will begin to experience signs and symptoms of PID, including lower abdominal pain, vaginal discharge, right upper quadrant abdominal pain, abnormal vaginal bleeding, fever/chills, dysuria, nausea/vomiting, and/or pain with intercourse. The symptoms may mimic those associated with appendicitis or urinary tract infection, so a careful history and physical exam are important in diagnosing PID.

Treatment consists of IV antibiotics, which the patient may be receiving when transport is initiated. CCTPs must be aware of any drug interactions when transporting patients on an antibiotic regimen. Complications of PID can include sepsis, septic shock, or abscess formation, which may require surgical drainage. Treatment of septic shock or sepsis should follow the standard protocol.

Recurrent PID can cause formation of scar tissue, which then leads to chronic pelvic pain, increases the patient’s risk for ectopic pregnancies, or impairs functionality of the reproductive system. As a result, 10% of the 1 million women diagnosed per year with PID will ultimately become infertile.

Signs and Symptoms

Pelvic Inflammatory Disease

- Back and abdominal pain
- Vaginal discharge
- Abnormal vaginal bleeding
- Pain with intercourse
- Painful urination
- Low-grade fever

Differential Diagnosis

Pelvic Inflammatory Disease

- Appendicitis
- Urinary tract infection
- Ovarian cyst or torsion

Transport Management

Pelvic Inflammatory Disease

- Continue the administration of IV antibiotics.
- Treat sepsis or septic shock per protocol.

Toxic Shock Syndrome

Toxic shock syndrome results from the release of bacterial toxins into the body, specifically following infection with *Staphylococcus aureus*, *Streptococcus pyogenes*, or *Clostridium sordellii*. While it has many potential underlying causes, historically this condition has been associated with tampon use. Toxic shock syndrome from *S aureus* was initially identified in the late 1970s. In the 1980s, when menstruating women began using superabsorbent tampons, which allowed for bacterial overgrowth, the syndrome was again seen. The composition of tampons has since changed, and the incidence of toxic shock syndrome has decreased. The CDC now reports that only 10 in every 100,000 menstruating women will develop a bacterial infection leading to toxic shock syndrome.

Signs and symptoms occur secondary to toxin release from bacteria into the bloodstream. They include high fever, malaise, headache, body rash, skin shedding, vomiting, diarrhea, and signs and symptoms of shock, including tachycardia and hypotension. Treatment includes airway management, fluid resuscitation, source control, and IV antibiotics such as clindamycin and vancomycin.

Signs and Symptoms

Toxic Shock Syndrome

- High fever
- Malaise
- Vomiting/diarrhea
- Skin shedding
- Body rash
- Headache
- Hypotension

Transport Management

Toxic Shock Syndrome

- Manage the airway.
- Treat sepsis or septic shock according to local protocols, with IV fluids and pressor support as indicated.
- Continue the administration of IV antibiotics.

Ovarian Cysts

An **ovarian cyst** is a pouch or sac that can grow in the ovaries. These cysts are quite common, occurring in approximately 8% to 18% of the female population. The majority are benign and resolve on their own; however, some are malignant. Ovarian cysts are categorized into four main groups:

- Functional ovarian cysts: often asymptomatic, self-resolving in 6 to 8 weeks
- Teratomas: can contain body tissue, hair, and skin, and rarely can become cancerous over time
- Cystadenomas: large but mostly benign
- Endometriomas: made up of endometrial tissue

Ovarian cysts are often undetectable and, as noted previously, may resolve on their own. Nevertheless, a small percentage may continue to grow and cause lower abdominal pain and pelvic pressure. On occasion, larger cysts can cause the ovary to twist on itself, a gynecologic emergency known as ovarian torsion. Cysts can also rupture, causing sharp, severe pain, and, if hemorrhagic, can cause bleeding into the abdomen.

Treatment typically consists of pain management with NSAIDs; however, complications such as torsion, cyst rupture, or malignancy may necessitate emergent surgical removal. During transport, ovarian cyst pain may be controlled with NSAIDs, but consider morphine or fentanyl for patients with severe pain. Also consider alternative diagnoses such as ovarian torsion, ectopic pregnancy, and appendicitis.

Diagnostic Evaluation

Most ovarian cysts are found incidentally on pelvic exam or ultrasonography. Emergent diagnosis is made through ultrasonography and Doppler flow studies that can monitor blood flow as well as cyst size and location. A computed tomography (CT) scan and magnetic resonance imaging (MRI) are useful alternatives, although usually not required, as ultrasonography is the preferred imaging modality. There is no specific laboratory technique to test for an ovarian cyst **FIGURE 22-26**.

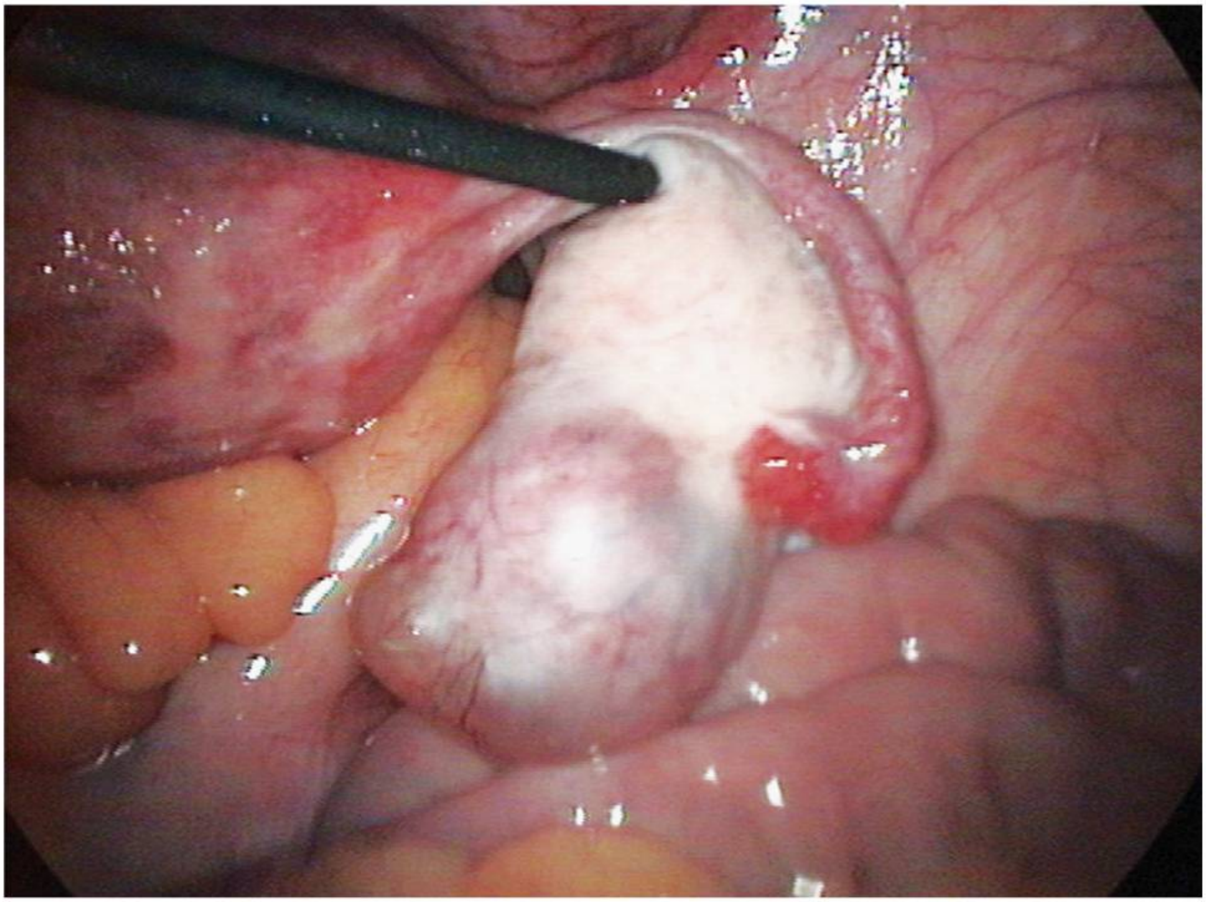

FIGURE 22-26 An ovarian cyst.

© Dr. Najeeb Layyous/Science Source.

Underlying and resultant conditions related to the cyst may be detected with blood tests, which can also help determine the differential diagnosis. A complete blood count, for example, can detect leukocytosis related to an infectious process. A decreased hematocrit value may indicate anemia, and prolonged PT and PTT times can detect clotting abnormalities that may complicate the healing process. Cancer antigen 125 (CA-125) levels greater than 35 U/mL suggest carcinoma as the origin of the cyst. CA-125 is a surface protein that is found on normal ovarian tissue cells and carcinomas; its level increases with abnormal excessive tissue growth. Blood and cervical cultures should be monitored for signs of infection. Last, a urinalysis is helpful in determining whether any blood is present in the urine.

Ruptured Ovarian Cysts

Ovarian cysts may rupture spontaneously or following trauma. Hemorrhage, which may be either mild or severe, frequently occurs when a cyst ruptures. If a rupture with hemorrhage has occurred, patients may present with increased lower abdominal and pelvic pain, vaginal bleeding, and hypovolemia leading to shock. The rupture of an ovarian cyst causes pelvic pain. Corpus luteal cysts occur during the final 1 to 2 weeks of the menstrual cycle, and their rupture can lead to pelvic inflammation and hemorrhage.

Treatment for patients with a ruptured ovarian cyst includes controlling any immediate life threats. Definitive management occurs at the hospital and often involves laparoscopic surgery to control bleeding and remove the cyst.

Signs and Symptoms

Ruptured Ovarian Cyst

- Increased lower abdominal and pelvic pain
- Vaginal bleeding
- Hypovolemia leading to shock

Differential Diagnosis

Ruptured Ovarian Cyst

- Ectopic pregnancy
- Hematuria
- Appendicitis
- Diverticulitis
- Bowel obstruction
- Ovarian tumor
- Ovarian torsion
- Salpingitis (inflammation of the fallopian tubes)
- Inflammatory bowel disease
- Pelvic inflammatory disease

Transport Management

Ruptured Ovarian Cyst

- Control any immediate life threats.
- Evaluate for hypovolemic shock; treat per protocol with IV fluids and pressors as indicated.
- Manage pain.

Ovarian Torsion

In some cases, an enlarged ovary, either by itself or as a result of another condition, will twist and limit its blood supply—a condition called **ovarian torsion** **FIGURE 22-27**. Ovarian torsion causes lower abdominal pain in females, which initially presents similar to appendicitis or ectopic pregnancy. The presentation typically involves acute onset of severe pelvic pain in a woman with an adnexal mass (a mass felt in the area of the uterus, ovaries, and fallopian tubes), often accompanied by nausea and vomiting. Most commonly, torsion occurs as a result of ovarian cysts. Cysts larger than 5 cm are mostly likely to torse. Pregnancy is also an independent risk factor for ovarian torsion. When not treated rapidly, this condition can lead to ovarian infarction and necrosis. Pregnant, nonpregnant, and postmenopausal women are all at risk for ovarian torsion.

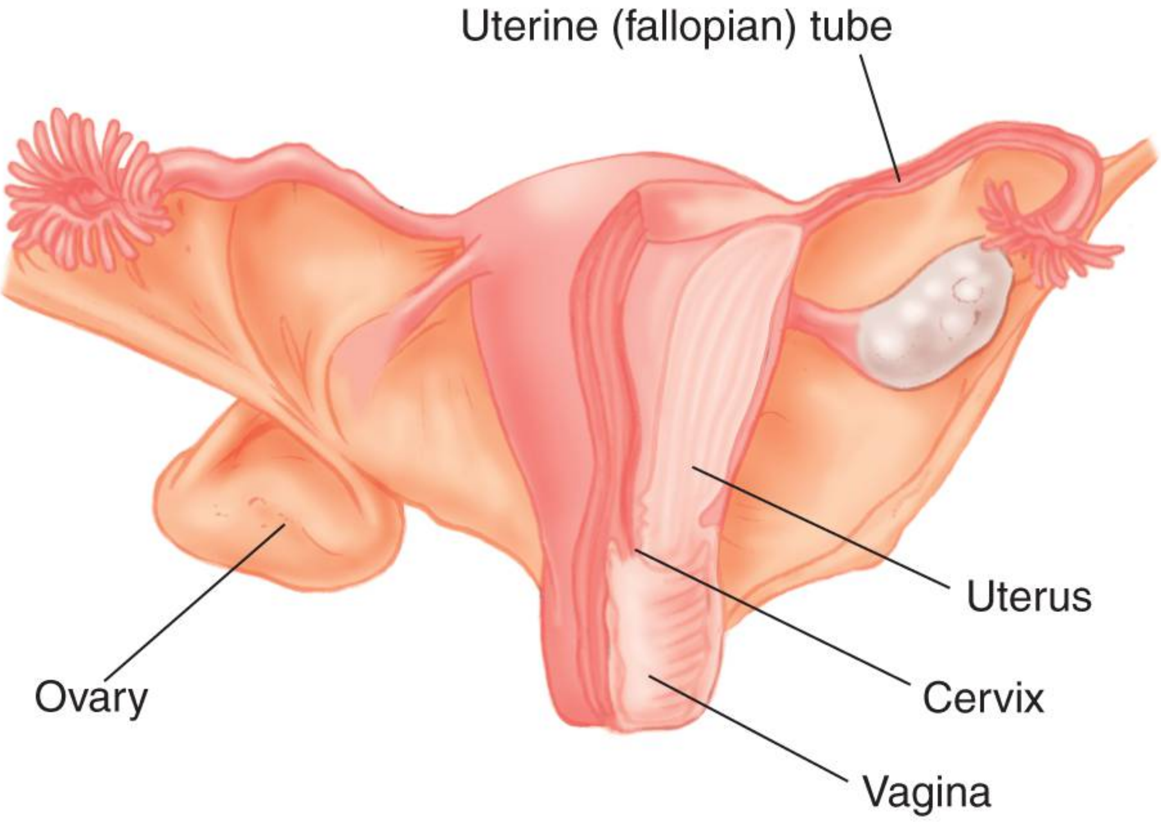

FIGURE 22-27 Ovarian torsion.

© Jones & Bartlett Learning.

It is important to immediately exclude the possibility of pregnancy prior to proceeding with specific treatment for ovarian torsion. The CCTP can initiate this process by taking a thorough history, including sexual history and the date of the patient's last menstrual cycle. Pelvic ultrasonography is the preferred method of diagnosis, with an enlarged ovary typically being observed on the imaging. Laparoscopic **oophoropexy**, in which the ovary is moved out of the distorted position, is the most common treatment.

Transport Management

Ovarian Torsion

- Manage pain (administer morphine or fentanyl).

Gynecologic Trauma

Examples of gynecologic trauma include lacerations and hematomas. Lacerations can result from direct trauma to the vagina, vulva, labia minora, or labia majora. Management includes bleeding control with direct pressure and vaginal packing, as indicated, and treatment of possible hypovolemic shock.

A hematoma can result from blunt trauma to the vulva, also known as a straddle injury. Swelling with purple discoloration occurs, which can be treated with ice and compression. Consider indwelling urinary catheterization if the hematoma expands to compress the urethra, causing bladder outlet obstruction.

Signs and Symptoms

Vaginal Laceration

- Significant bleeding
- Swelling and pain

Vulvar Hematoma

- Swelling with purple discoloration of the vulva

Transport Management

Vaginal Laceration

- Apply direct pressure and/or pack with gauze as indicated.
- Treat hypovolemic shock per protocol.
- Manage pain.

Vulvar Hematoma

- Administer ice.
- Provide compression.
- Monitor the indwelling catheter, if one is placed.

Summary

The dynamic changes that occur with pregnancy can prove challenging for the CCTP who is treating a pregnant patient. For the pregnant patient, each day is different physiologically as a new life grows inside her. Gynecologic emergencies do not require significantly different treatment during critical care transport, but, as always, are important to treat properly and with sensitivity.

CASE STUDY

You are dispatched to transport a female patient from the local community hospital to the tertiary care center 30 minutes away. She is 38 years old and 32 weeks pregnant. She is carrying twins after undergoing in vitro fertilization. The patient presented to the local hospital with complaints of headache and right upper quadrant pain.

Upon arrival, you receive a report from the nurse. Currently, the patient is hemodynamically stable. Her BP is 135/85 mm Hg, heart rate is 72 beats/min, and oxygen saturation is 97% on room air. Fetal heart rate tracings have been reassuring for both babies. Blood work drawn on arrival revealed a white blood cell count of 11,000 mm^3, a hemoglobin level of 11.2 g/dL, and a platelet count of 98,000 mm^3. The patient's electrolytes are all within normal range and her liver function tests are within normal limits. The only abnormality is a creatinine level of 1.5 mg/dL. Her initial BP on arrival to the community hospital was elevated, at 150/92 mm Hg. The hospital providers obtained IV access with an 18-gauge catheter in the antecubital fossa. Magnesium sulfate was administered starting with a 4-g load, and now continuing at 2 g/h via IV line. The patient is awake and alert and appears to be in no acute distress. You confirm the IV access is patent. You confirm the medication is running through the pump at the prescribed amount. The patient is transferred to your gurney with fetal monitors in place.

Five minutes into your transport, you notice a change in the patient's BP, which now measures 165/110 mm Hg. She complains of worsening headache. You confirm that the magnesium sulfate is being administered. You contact medical control and request recommendations. You are advised to increase the magnesium to 4 g/h. Ten minutes later, the patient reports difficulty breathing. Her BP is unchanged, but the oxygen saturation level is now in the mid-80s. You administer supplemental oxygen and continue your transport. Despite the oxygen, the patient has worsening dyspnea and is becoming less responsive. You apply nasal capnography and determine the end-tidal carbon dioxide ($ETCO_2$) is 67 mm Hg. Realizing the patient is experiencing magnesium toxicity, you turn off the magnesium and begin assisting respirations. You arrive at the tertiary care center while you are performing bag-mask ventilation.

1. What is the patient’s underlying diagnosis?
2. Was increasing the magnesium the correct response?
3. What is the antidote to magnesium sulfate toxicity?
4. What would have been a better option to control the patient’s BP?

Analysis

You recognize that this patient has preeclampsia, based on her elevated BP and her low platelet count. The initial treatment for the patient’s preeclampsia was correct, with a magnesium load of 4 g continuing at 2 g/h. The patient’s risk factors for preeclampsia were her age (older than 35 years) and multiple-gestation pregnancy. Assisted reproduction also increases the risk of preeclampsia.

Increasing the magnesium in this patient in response to her increasing headache and BP was inappropriate. This patient is at increased risk of magnesium toxicity due to her impaired renal function. A creatinine level of 1.1 mg/dL or greater indicates impaired renal function in a pregnant woman without preexisting renal disease. Magnesium is excreted via the kidneys. Because the patient was experiencing difficulty breathing, the initial response should have been to reduce the magnesium and assess respiratory status. An $ETCO_2$ level of 67 mm Hg suggests respiratory insufficiency; assisting ventilations would have been more helpful than administering oxygen. After you ultimately identified that the patient was experiencing magnesium toxicity, the decision to turn off the magnesium was correct. However, when the patient’s respiratory status requires assisted ventilations, an appropriate intervention would be to administer calcium gluconate 1 g over 3 minutes to reverse the effects of the magnesium.

You received faulty advice from your medical control. The correct medical advice would have been to administer labetalol 20 mg IV, hydralazine 10 mg IV, or nifedipine 10 mg immediate release. BP would then need to be reassessed in 10 to 15 minutes. When BP is in the severe range, patients are at increased risk of stroke. This condition should be managed in a similar fashion to a hypertensive emergency. Magnesium is not indicated to manage BP; in this case it was being used to prevent seizure.

The patient was given calcium gluconate upon arrival and did not require intubation. She was taken to the operating room to undergo a cesarean section for preeclampsia with severe features. She delivered two healthy, although premature, infants who are doing well in the neonatal intensive care unit.

PREP KIT

Ready for Review

- The physiologic changes induced by pregnancy and the presence of potentially life-threatening pathologic conditions can make management of obstetric patients challenging.
- The female reproductive system, which is regulated by hormones, experiences an approximately 28-day menstrual cycle.
- The placenta provides the fetus with oxygen and vital nutrients. It grows with the fetus and includes a thin membrane that separates the maternal and fetal blood supplies.
- As the fetus grows and the ratio of fetal size to amniotic fluid decreases, the fetus becomes more vulnerable to trauma.
- Pregnancy alters the normal physiology of females, affecting nearly every organ system.
- During pregnancy, cardiac output increases, circulating blood volume expands, and peripheral venous pressure increases. BP and levels of serum albumin and serum protein decrease as pregnancy progresses.
- The growth of the fetus increases the demand for oxygen and reduces the oxygen reserves in the pregnant woman.
- Gastroesophageal reflux is more common during pregnancy, and a pregnant patient with an altered level of consciousness has a greater likelihood of aspiration.
- Pregnancy places increased strain on the renal and endocrine systems.
- Hormonal changes in the pregnant patient can cause dermatologic changes, including acne, linea nigra, chloasma, and rashes.
- Obstetric patients require a complete physical exam, including maternal and fetal hemodynamic monitoring and, if in labor, external vaginal evaluation for the presence of crowning.

- If delivery is imminent, CCTPs should seek to assist in the delivery at the hospital rather than attempt delivery during transport.
- To ease the anxiety caused by the stress and noise of transport, analgesics may be administered to patients in labor.
- When necessary, CPR should be performed on pregnant patients by following standard guidelines, with constant chest compressions and limited interruptions for ventilation and gas exchange.
- If defibrillation of the pregnant patient is necessary, fetal monitors should be removed before administering a shock.
- The developing fetus has a very small reserve of oxygen, usually only 1 to 2 minutes, if the supply from the mother is cut off or diminished. If the fetus does not receive enough oxygen, the heart rate decreases and death ensues.
- The well-being of the fetus may be assessed by auscultation for heart rate and movement, use of a hand-held Doppler ultrasonograph or fetal stethoscope, and electronic fetal monitoring.
- Electronic fetal monitoring records the fetal heart rate and uterine contractions on a fetal monitoring strip. Late or variable decelerations in the heart rate are abnormal and may indicate fetal distress.
- The normal heart rate of a fetus is between 110 and 160 beats/min. Fetal heart tones should be recorded for at least 30 to 60 seconds every 15 minutes during labor. During high-risk transports, electronic fetal monitoring should be performed continuously.
- Any vaginal bleeding during the third trimester of pregnancy must be regarded as an emergency.
- Bleeding may indicate an early pregnancy loss, ectopic pregnancy, abruptio placentae, placenta previa, or uterine rupture.
- CCTPs should be aware of the warning signs of dangerous medical conditions, such as gestational hypertension,

preeclampsia, eclampsia, and HELLP syndrome, and the appropriate treatment protocols.

- Labor includes three distinct stages as the cervix dilates, the baby descends through the birth canal and is born, and the placenta is delivered.
- During delivery, a crucial fetal transition occurs as the baby begins to breathe independently of the oxygen supply from the mother. Anything that delays the decline in pulmonary pressure (and therefore delays breathing) during the fetal transition can lead to delayed transition, hypoxia, brain damage, and death.
- Preterm labor and fetal immaturity are the leading causes of neonatal mortality.
- Tocolytic agents may be administered to help stop preterm labor.
- A baby may present in the vertex, frank breech, complete breech, incomplete breech, or footling breech position for birth.
- In the event of a prolapsed cord, the pregnant patient should be given oxygen, placed in the knee-chest position, and transported rapidly.
- If shoulder dystocia occurs (ie, the infant is too large to travel through the birth canal unassisted), a rapid treatment plan is needed, which may include positioning the pregnant patient using the McRoberts maneuver, suprapubic pressure, or delivery of the posterior arm.
- During the interval between multiple births (such as twins or triplets), transport should continue. Transport should be interrupted only if the next infant begins to emerge from the birth canal.
- Once delivery is complete, care for both the mother and the infant should continue, to include examining the mother’s perineum for tears, monitoring the infant’s Apgar score, performing fundal massage, and drying and warming the infant.
- CCTPs must monitor the antepartum patient for possible postpartum hemorrhage, amniotic fluid embolism, and uterine

rupture.

- Pelvic inflammatory disease is an infectious process causing inflammation in the reproductive system, including the uterus, fallopian tubes, and ovaries. If untreated, it may cause infertility.
- CCTPs should be prepared to treat gynecologic emergencies such as toxic shock syndrome, ovarian cysts, ruptured ovarian cysts, and ovarian torsion.
- Ovarian cysts are typically a result of follicular maturation during the normal female menstrual cycle and are often undetectable and self-resolving. A small percentage may continue to grow and cause lower abdominal pain.
- Symptoms of a cyst include abdominal pain, nausea, vomiting, and, with very large cysts, frequent urination from bladder pressure.
- Ovarian cyst diagnosis is made through ultrasonography and Doppler flow studies, which can monitor blood flow as well as cyst size and location. Consider alternative diagnoses such as ovarian torsion, ectopic pregnancy, and appendicitis.
- An ovarian cyst may rupture spontaneously or following trauma, resulting in hemorrhage. If hemorrhage is present, patients may present with increased lower abdominal and pelvic pain, vaginal bleeding, and hypovolemia leading to shock.
- Treatment for a patient with a ruptured ovarian cyst includes controlling any immediate life threats, including evaluation for hypovolemic shock and maintaining adequate BP with isotonic fluids if the patient is in shock.
- Ovarian torsion is often a cause of lower abdominal pain in females; it initially presents similarly to appendicitis or an ectopic pregnancy.
- Gynecologic trauma includes vulvar hematoma (straddle injury), which is treated with ice and compression.
- Gynecologic emergencies do not require significantly different treatment during critical care transport but must be treated

properly and with sensitivity.

Vital Vocabulary

amniotic fluid embolism (AFE) A rare and poorly understood condition in which fetal tissue crosses over the placental barrier into the maternal circulation. It can occur antepartum and postpartum, and is believed to be associated with an anaphylactoid response leading to multisystem organ failure and disseminated intravascular coagulation.

breech A delivery presentation in which the presenting part is not the head.

chloasma A dermatologic condition affecting pregnant women in which darkened skin patches appear on the cheeks and forehead.

complete breech A delivery presentation in which the buttocks present first and the legs are crossed inside the uterus.

dilation and curettage (D&C) A surgical procedure in which the cervix is opened and the uterus scraped of tissue.

early pregnancy loss Expulsion of the fetus that occurs naturally; also called miscarriage or spontaneous abortion.

eclampsia The condition that exists once a patient with preeclampsia develops seizures; it causes serious maternal complications. Warning signs of the transition from preeclampsia to eclampsia include severe headache, scotomata, hyperreflexia, epigastric pain, and anxiety.

ectopic pregnancy A pregnancy in which the ovum implants somewhere other than the uterine endometrium.

endometrium The inner mucous membrane of the uterus.

external fetal monitoring Electronic heart monitoring of the fetus while in utero, performed via electrodes placed on the pregnant woman’s abdomen.

footling breech A delivery presentation in which both feet extend into the birth canal.

foramen ovale The opening in the fetal heart that allows blood to flow from the right atrium to the left atrium of the fetus, bypassing the lungs prior to birth.

frank breech A delivery presentation in which the buttocks present first, both of the infant’s hips are flexed, and the feet are near the fetus’s head.

gestation Period of time elapsed from conception to birth. For humans, the full period is normally 40 weeks.

gestational diabetes A condition in which a woman without previous diabetes develops high blood glucose, especially during the third trimester.

gestational hypertension The occurrence of hypertension in a pregnant woman, usually after 20 weeks’ gestation, defined as a blood pressure of 140/90 mm Hg or greater in a woman with a previously normal blood pressure. Also called pregnancy-induced hypertension.

HELLP syndrome A hemolytic disorder that occurs during the latter stages of gestation, usually after the 20th week, and whose clinical findings include hemolytic anemia, elevated liver enzyme levels, and a low platelet count. Patients will present with blurred vision, abdominal pain, headache, and edema.

hydroureteronephrosis Dilation and obstruction of a ureter, which results in dilation of the connected kidney.

incomplete breech A delivery presentation in which the buttocks present first and one foot extends into the birth canal.

introitus The visible opening to the vagina.

linea nigra A dermatologic condition affecting pregnant women in which a darkened line develops from the navel to the vagina.

metabolic acidemia A condition characterized by the body's production of excessive quantities of acid or the kidneys' inability to remove enough acid from the body.

metabolic acidosis A pathologic condition characterized by a blood pH of less than 7.35, which is caused by an accumulation of acids in the body from a metabolic cause.

oophoropexy Surgery in which the ovary is attached to the pelvic sidewall so it cannot twist on itself.

ovarian cyst A fluid buildup within an outcropping of tissue from the ovary. If such a cyst ruptures, significant bleeding can occur.

ovarian torsion Twisting of an ovary about its ligaments, resulting in ischemia and possibly necrosis.

partial thromboplastin time (PTT) A value that represents the intrinsic coagulation pathway's clotting ability; also known as activated partial thromboplastin time (aPTT).

pelvic inflammatory disease (PID) An infection of the female upper organs of reproduction—specifically, the uterus, ovaries, and fallopian tubes.

precipitous delivery Delivery in less than 3 hours from the onset of regular contractions; may occur with premature labor.

preeclampsia A condition of late pregnancy that involves onset of hypertension and proteinuria that manifests with headache, visual changes, and swelling of the hands and feet; also called toxemia of pregnancy. It may be classified as occurring with or without severe features.

premature Underdeveloped; refers to infants born before 36 weeks from the first day of the last menstrual period.

premature prelabor rupture of membranes (PPROM) A rupture of membranes in a pregnant woman signaled by a gush of fluid or constant fluid leakage; it accounts for as many as 50% of all preterm deliveries.

preterm labor Labor occurring before 36 weeks' gestation, leading to early birth.

prolapsed cord A delivery presentation in which the umbilical cord passes through the birth canal in advance of the infant.

proteinuria Protein levels detected in the urine.

prothrombin time (PT) A value that represents the extrinsic coagulation pathway's clotting ability by taking into account various clotting factors, fibrinogen, the prothrombin ratio, and the international normalized ratio.

pruritic urticarial papules and plaques of pregnancy (PUPPP) An itchy rash affecting pregnant women; it may be either isolated to one region or systemic.

shoulder dystocia A condition in which the infant's shoulders are too large to travel through the birth canal without additional clinical maneuvering of the infant.

supine hypotensive syndrome Low blood pressure resulting from compression of the inferior vena cava by the weight of the pregnant uterus when the mother is supine.

term Used to describe an infant delivered at 39 to 40 weeks' gestation.

thrombocytopenia Reduction in the number of platelets.

tocolytics A group of medications used to suppress preterm labor.

toxic shock syndrome A condition that results from the release of bacterial toxins into the body, specifically following infection with *Staphylococcus aureus*, *Streptococcus pyogenes*, or *Clostridium sordellii*.

vertex A fetal position in which the head is the lowest part of the fetus, resulting in the head presenting first during delivery; the normal delivery presentation.

CHAPTER 23

Neonatal Emergencies

Patricia R. Chess, MD
Yogangi Malhotra, MD
Nirupama Laroia, MD

OBJECTIVES

After completing this chapter, you will be able to:

1. Define the terms *newborn*, *neonate*, and *term newborn* (p 1233).
2. Discuss the roles of the CCTP when caring for a neonate (p 1233).
3. Recognize anatomy and physiology unique to a neonate, including differences in thermoregulation, respiratory structure and function, oxygen transport, cardiovascular function, renal function, fluid and electrolyte balance, central nervous system, and skeletal system (pp 1233–1237).
4. Understand how problems with transitional circulation can result in neonatal emergencies (p 1236).
5. Describe developmental aspects of pain in the neonate (p 1237).
6. Discuss anatomic and physiologic differences in the premature infant, including how these relate to patient care (p 1237).
7. Discuss medical complications for which late preterm infants are at risk (p 1237).
8. Identify important antepartum and intrapartum risk factors that can affect labor, delivery, and the neonate (p 1238).
9. Understand the pathophysiology that is associated with antepartum and intrapartum factors that can affect labor, delivery, and the neonate (pp 1237–1238).
10. Identify when a CCTP would use the Apgar score in caring for a newborn (p 1238).
11. Discuss neonatal assessment, stabilization, and treatment (p 1237).
12. Discuss how to prepare for and provide neonatal resuscitation (p 1240).
13. Identify situations in which neonatal resuscitation should be performed (p 1240).
14. Describe the appropriate assessment technique when examining a neonate (p 1240).
15. Explain the initial steps in resuscitation of a neonate (p 1240).
16. Describe methods that can be used to improve airway and breathing in a neonate with inadequate respiration (p 1241).

17. Describe free-flow oxygen delivery (p 1241).
18. Explain the appropriate assisted ventilation for a neonate (p 1242).
19. Describe the appropriate endotracheal intubation technique for a neonate (p 1247).
20. Identify when an orogastric tube should be inserted in a neonate (p 1249).
21. Describe the procedure for inserting an orogastric tube in a neonate (p 1249).
22. Describe the appropriate chest compression and ventilation technique for a neonate (p 1250).
23. Discuss indications for medications, dosages, and routes of administration for a neonate (p 1252).
24. Discuss the use of ventilators during neonatal transports (p 1256).
25. Discuss the pathophysiology, assessment findings, management, and treatment plan for the following respiratory emergencies in a neonate: apnea, meconium aspiration, pneumonia, respiratory distress syndrome, pneumothorax, and respiratory acidosis (pp 1257–1260).
26. Distinguish between primary and secondary apnea (p 1257).
27. Discuss the causes, assessment, and management of primary and secondary apnea (p 1257).
28. Describe how to perform needle thoracentesis for pneumothorax decompression in a neonate (p 1259).
29. Determine when vascular access is indicated for a neonate (p 1261).
30. Recognize congenital anomalies that may lead to compromise of the neonate (p 1261).
31. Discuss the pathophysiology, assessment findings, and management of the following cardiovascular emergencies in a neonate: cyanosis, cyanotic congenital heart disease, tachyarrhythmias, bradyarrhythmias, cardiac arrest, persistent pulmonary hypertension, shock, anemia, and hyperbilirubinemia (pp 1261–1267).
32. Describe how to perform umbilical vein catheterization in a neonate (p 1264).
33. Discuss the pathophysiology, assessment findings, and management of the following gastrointestinal emergencies in a neonate: gastroschisis, omphalocele, gastrointestinal obstruction and vomiting, acute intestinal perforation, hematemesis and bleeding from the rectum, volvulus, intussusception, and diarrhea (pp 1269–1274).
34. Explain appropriate fluid selection when vascular access is indicated for a neonate (p 1270).
35. Discuss the management of infectious diseases and sepsis in the neonate (p 1274).
36. Discuss the management of hyperthermia and hypothermia in the neonate (p 1274).
37. Discuss the management of toxic exposure in the neonate, including the appropriate treatment for the neonate with narcotic depression (p 1274).
38. Discuss the pathophysiology, assessment findings, and management of the following trauma/birth injuries in the neonate: head and neck injuries, nerve injuries, bone injuries, and abuse/maltreatment (pp 1275–1276).
39. Discuss the pathophysiology, assessment findings, and management of the following neurologic conditions in the neonate: seizures, hypoxic ischemic encephalopathy,

and lethargy (pp 1276–1278).

40. Discuss the pathophysiology, assessment findings, and management of the following metabolic conditions in the neonate: metabolic acidosis, hypoglycemia, hypocalcemia, and inborn errors of metabolism (pp 1278–1279).
41. Discuss the use of an incubator (p 1280).
42. Recognize the emotional impact of a neonate’s illness or injury, and the need for information, empathy, and compassion for the parent/guardian during a critical care transport (p 1280).
43. Discuss risks associated with critical care transport, including factors unique to air transport of a neonate (p 1282).

Introduction

The care of a newborn or neonate must be tailored to meet the unique needs of this population. The term **newborn** refers to an infant within the first few hours after birth; a **neonate** is an infant within the first 28 days after birth **TABLE 23-1**. A **term newborn** is one delivered between 37 0/7 and 41 6/7 weeks' **gestation**. Term can be further defined as early term (37 0/7 to 38 6/7 weeks' gestation), full term (39 0/7 to 40 6/7 weeks' gestation), and late term (41 0/7 to 41 6/7 weeks' gestation).

TABLE 23-1 Infant Age Terminology

Term	Age
Newborn	Within the first few hours after birth
Neonate	Within the first 28 days after birth
Infant	Age 1 month to 1 year
Term newborn	Delivered between 37 and 42 weeks' gestation
Preterm	Delivered before 37 weeks' gestation

© Jones & Bartlett Learning.

This chapter reviews challenges that the critical care transport professional (CCTP) may face when transporting a neonate, including recognizing the anatomic differences in a neonate and understanding the physiologic changes that occur in a newborn during the transition from fetal circulation after birth, thermoregulation, and the special needs of infants delivered prematurely, or births complicated by other factors. The steps involved in neonatal resuscitation, the pathophysiology of common congenital anomalies, medical emergencies encountered during the first month after birth, and the effects of these factors on the process of transporting a critically ill infant are also discussed.

Additional skilled care interventions—such as intubation, obtaining peripheral intravenous (IV) access, placement of umbilical venous and arterial lines, needle aspiration of the chest, and chest tube placement—are needed for approximately 6% of neonates, with the rate of complications increasing as the neonate's birth weight and gestational age decrease. In the United States, approximately 80% of the 30,000 babies born each year weighing less than 3 pounds (1,500 g) require resuscitation. Because both short- and long-term outcomes in neonates have been linked to initial stabilization efforts, it is imperative that CCTPs anticipate problems with neonates, be knowledgeable about how to deal with them, have the appropriate resuscitation equipment readily available, and carefully consider the neonate's ultimate transport plan.

Anatomy and Physiology of a Neonate

Neonates are not small children. That is, newborn infants have anatomic differences and undergo unique physiologic changes at birth, placing them at special risks.

Thermoregulation

Neonates become cold easily due to a variety of factors. Their potential for heat loss is greater due to their high body surface area-to-body weight ratios and limited subcutaneous fat stores. Neonates also lose heat to the environment through the mechanisms of thermal conduction, convection, radiation, and increased evaporative heat loss through the skin. Heat production is limited because of their low glycogen stores, small supply of brown fat (brown fat is used in older people as a heat energy source), and limited capacity to generate heat by shivering. This is especially true in infants who are small for their gestational ages and prematurity. Neonates have a relatively narrow range for their **neutral thermal environment**, the temperature at which maintenance of normal body temperature requires only minimal metabolic expenditure. Although the term newborn is able to increase heat production through brown fat metabolism (nonshivering thermogenesis), this process comes at the cost of increased oxygen consumption. Hypothermia in infants is associated with hypoxia, prolonged coagulation time with reduced platelet function and increased risk of intraventricular hemorrhage, reduced drug metabolism, cerebral depression, myocardial depression, acidosis, decreased immunity, patient discomfort, and increased mortality. The preterm infant is particularly vulnerable because the immature skin is thin, allowing significant heat (and evaporative fluid) loss to occur.

To help maintain normothermia in neonates, CCTPs should use prewarmed blankets and equipment, including a prewarmed transport incubator **FIGURE 23-1**, place a cap on the infant’s head, and minimize the infant's exposure to cold. It is recommended that the temperature of a newborn be maintained between 98°F and 100°F (36.5°C and 37.5°C) after birth through resuscitation or stabilization. It is important to avoid environmentally induced hyperthermia, because this condition is associated with increased energy expenditure, morbidity, and mortality.

In preparation for the birth of a preterm newborn, it is important to increase the ambient temperature of the room where the newborn will receive initial care to 73°F to 77°F (23°C to 25°C). For newborns delivered prior to 32 weeks' gestation, it is recommended that the newborn's lower body be covered with food-grade plastic wrap or a bag, and that a hat and thermal mattress be used. Temperature should be measured and recorded after birth and monitored as a measure of quality. A healthy baby can be placed skin to skin with the mother after resuscitation.

Respiratory Structure and Function

Lung development starts early in embryonic life, but the lungs are unable to sustain life ex utero until later in the canalicular stage of development, after approximately 23 weeks' gestation or 1 pound (500 g) of fetal weight. The neonatal lungs are small relative to the body size, with little respiratory reserve. **Surfactant** is present by 23 weeks' gestation, but surfactant deficiency is common before 32 weeks' gestation; thus, babies born prematurely may benefit from exogenous surfactant delivered endotracheally.

The neonate has a respiratory rate of 30 to 60 breaths/min with a tidal volume in the range of 5 to 7 mL/kg. The head is large in relation to the neonate's body, resulting in neck flexion and obstruction when the infant is in the supine position. Placing a rolled towel under the neonate's shoulders helps open the airway.

The infant's tongue occupies a proportionally larger intraoral volume than in older people, a difference that can lead to airway obstruction. Newborn infants are obligate nose breathers and may present with obstructive apnea when the nasal passages are blocked by a developmental defect (choanal atresia), edema of the nasal mucosa caused by vigorous suctioning, or secretions. Placing and maintaining an oral airway is often a sufficient intervention to stabilize a neonate with a fixed nasal obstruction during transport.

Another important airway anatomic feature of neonates is their relatively more cephalad and anterior larynx, a factor that needs to be considered when locating the vocal cords during intubation. When positive-pressure ventilation (PPV) is needed, attempts should be made to maintain physiologic tidal volume breaths because volutrauma, hypercapnia, and hypocapnia have been associated with bleeding in the brain (intraventricular hemorrhage), hearing loss, and chronic lung disease or bronchopulmonary dysplasia.

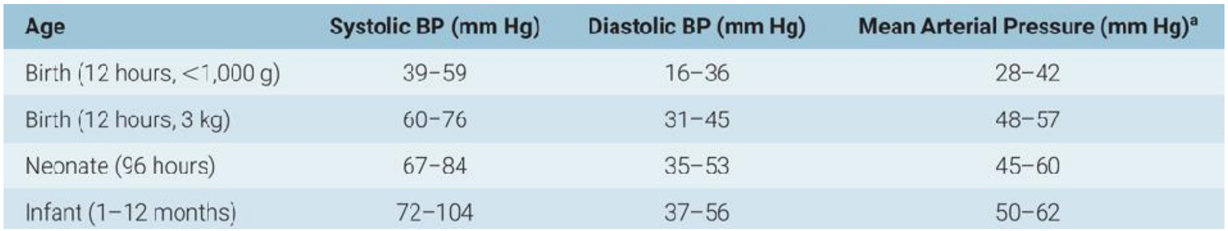
Oxygen Transport

Fetal hemoglobin (HbF) accounts for 70% to 80% of the total hemoglobin in the neonate. Fetal hemoglobin delivers oxygen to the fetus's tissues in the hypoxic condition found in utero, but tends to hold on to oxygen in the normal conditions after birth (ie, the oxygen dissociation curve is shifted to the left). Neonates have a high oxygen requirement (6 to 8 mL/kg/min versus 4 to 6 mL/kg/min in adults). Tissue oxygenation is achieved through a relatively high cardiac output (300 mL/kg/min versus 60 to 80 mL/kg/min in adults), high heart rate (120 to 160 beats/min), and high respiratory rate (30 to 60 breaths/min). Neonates do not tolerate interruption in oxygen delivery for any length of time, but rather become hypoxic and bradycardic quickly.

Cardiovascular Function

The heart rate, normally 100 to 205 beats/min in neonates, is an important determinant of cardiac output because the neonate's cardiac muscle is immature. Neonates respond to careful volume loading (fluid bolus of 10 to 20 mL/kg) with an increase in cardiac output, but they do not tolerate fluid overload. The two inotropic agents most commonly used in neonates are dopamine (used when an infant has cardiac compromise and is peripherally vasodilated from septic shock) and dobutamine (which also improves cardiac function but can exacerbate hypotension due to peripheral vasodilation). **TABLE 23-2** summarizes normal blood pressure (BP) for newborns through infants.

TABLE 23-2 **Normal Infant Vital Signs**



Age	Systolic BP (mm Hg)	Diastolic BP (mm Hg)	Mean Arterial Pressure (mm Hg)[a]
Birth (12 hours, <1,000 g)	39–59	16–36	28–42
Birth (12 hours, 3 kg)	60–76	31–45	48–57
Neonate (96 hours)	67–84	35–53	45–60
Infant (1–12 months)	72–104	37–56	50–62

[a] For practical purposes, approximations may be used, where the goal is for the mean arterial pressure (MAP) to be no lower than the gestational age. For example, a 28-week infant should have a MAP of no lower than 28 mm Hg, a 36-week newborn will have a MAP of no lower than 36 mm Hg, and so on.

Abbreviation: BP, blood pressure

Description

Transitional Circulation

In utero, the pulmonary vasculature has a high resistance, so most of the blood returning to the right atrium from the placenta (oxygenated blood) passes to the left atrium via the foramen ovale **FIGURE 23-2**. The oxygenated blood enters the left atrium, mixes with the small pulmonary return, and is pumped via the left ventricle and the aorta to the coronary arteries and the brain. Deoxygenated blood returns from the lungs to the left atrium, where it mixes with the oxygenated blood. Of the ejected right ventricular output, most blood flows to the aorta via the ductus arteriosus, mixing with the left ventricular output. Blood carried by the descending aorta perfuses various organs and the lower body. Umbilical arteries, which branch from the internal iliac arteries, lead to the placenta where blood is oxygenated.

© Jones & Bartlett Learning.

Description

With the clamping of the umbilical cord at birth (ie, removal of the low-resistance placenta), the newborn experiences a sudden rise in the systemic vascular resistance. Cardiorespiratory adaptation at birth results in an increased pulmonary blood flow and physiologic closure of the fetal shunts that allowed the blood to bypass the lungs—namely, the foramen ovale and ductus arteriosus.

With extrauterine breathing and expansion of the neonate’s lungs, tissue oxygenation increases, pulmonary vascular resistance decreases, and pulmonary blood flow increases. The increased pulmonary venous return to the left atrium raises the left atrial pressure above the right atrial pressure, closing the flap valve of the foramen ovale. With increasing left ventricular pressure and a decline in right ventricular pressures, a decrease or reversal of flow through the ductus arteriosus takes place. Anatomic closure may occur as early as 6 hours after birth, but complete occlusion may take as long as 6 weeks.

Pulmonary vascular resistance may increase with hypoxia, acidosis, cold stress, primary pulmonary disease such as meconium aspiration or pneumonia, or hypercarbia, causing persistent pulmonary hypertension, the return of left-to-right shunting through the ductus arteriosus and/or foramen ovale, profound hypoxia and cardiovascular compromise, and sometimes death. This process is exacerbated if the patient has systemic hypotension. Optimizing a neonate’s condition during transport, with special attention given to maintaining normothermia, optimal oxygenation, fluid status, and systemic BP, and minimizing acidosis and noise, will decrease the risk of severe persistent pulmonary hypertension evolving in the patient.

Patent ductus arteriosus is seen in 50% of extremely premature infants (less than 26 weeks’ gestation) and is a risk factor for intraventricular hemorrhage and necrotizing enterocolitis. Whereas immediate treatment for a patent ductus arteriosus during critical care transport is not indicated, minimizing fluid overload during transport can decrease the risk of a persistent symptomatic patent ductus arteriosus.

Some cardiac abnormalities depend on a patent ductal flow. In patients with these conditions, circulatory collapse may occur with the closure of the ductus, often at 2 to 7 days of age. Maintenance of ductal patency with prostaglandins during transport can be lifesaving and is discussed further in the section on cyanotic congenital heart disease (CHD) later in this chapter.

Renal Function

Nephrogenesis is completed at 36 weeks' gestation, at which point no further nephrons are produced. Additional increases in renal mass result from the growth of tubules. The glomerular filtration rate at term is low and reaches the adult indexed values only at 2 years of age. The newborn's creatinine level at birth reflects the mother's creatinine level, but then falls to reflect the neonate's renal function by 1 week of age. Over the first few months of life, tubular function matures; infants usually produce urine that is isotonic to plasma, but if required can concentrate their urine to achieve an osmolality of 500 to 700 mOsm/kg H_2O. Adult values (urinary osmolality, typically 1,200 to 1,400 mOsm/kg H_2O) are reached by 1 year of age. Infants tolerate fluid restriction poorly and become dehydrated quickly.

Fluid and Electrolyte Balance

The extracellular fluid compartment is proportionately greater in neonates, with total body water representing 85% of body weight in premature babies and 75% of body weight in term babies, compared to 60% of body weight in adults. Contraction of the extracellular fluid compartment and weight loss in the first few days after birth is a normal physiologic process, due in part to diuresis induced by atrial natriuretic peptide secondary to increased pulmonary blood flow and stretching of the left atrial receptors. After this period of negative water and sodium balance, water and sodium requirements increase to match those of the growing infant. For this reason, fluids should be restricted in the infant until the expected postnatal weight loss has occurred. Liberal fluid regimens in the first few days of life have been shown to be associated with worse outcomes in premature infants (eg, increased patent ductus arteriosus, necrotizing enterocolitis, and death). Fluid requirements increase incrementally from day 1 of life (60 to 100 mL/kg/d for term to extremely low-birth-weight infants, respectively) to 150 mL/kg/d at 1 week of life.

The solution 10% dextrose in water ($D_{10}W$) is commonly used for IV fluid maintenance in a newborn for the first 24 hours after birth.

After 24 hours, once adequate urine output is established, 10% dextrose in 0.25% saline is used as a maintenance fluid in a neonatal transport; 10 mEq of potassium chloride in 500 mL may be added unless findings show abnormal electrolyte levels or renal function, necessitating adjustment. In general, a full-term infant needs 60 mL/kg/d of fluid, a very-low-birth-weight infant (less than 3 pounds [1,500 g]) needs 80 mL/kg/d, and an extremely low-birth-weight infant (less than 2 pounds [1,000 g]) needs 100 mL/kg/d on day 1 of life, increasing by 10 mL/kg/d each day until reaching total fluids of 150 mL/kg/d.

Central Nervous System, Nociception, and the Stress Response

The lower limit for cerebral autoregulation in neonates is not known but is thought to approximate a cerebral perfusion pressure of 30 mm Hg. In general, neonates are considered to have pressure-passive cerebral circulation: As mean arterial pressure falls, cerebral blood flow falls, and vice versa. Appropriate mean arterial BPs for extremely premature neonates have not been determined, but it is generally acknowledged that an acceptable mean arterial pressure equates to the gestational age of the newborn. It is also important to minimize stress in neonates and use appropriate sedation for procedures to minimize BP peaks in these patients that can lead to intraventricular hemorrhage.

Developmental Aspects of Pain

Neonates, including premature neonates, show well-developed responses to painful stimuli. Pain in neonates should be treated using appropriate analgesic measures, such as bundling and a pacifier dipped in $D_{10}W$ for blood draws or IV placement, or local anesthetics or opiates for more invasive procedures.

Skeletal Development

Neonates have incomplete ossification of bones, and their tissues are more fragile than those in older children and adults, making them more susceptible to both soft-tissue and bony injuries. This risk should be considered when providing cardiopulmonary resuscitation (CPR) because neonates are at higher risk of rib fractures and liver laceration during chest compressions. The optimal technique for chest compressions in neonates is reviewed later in the section on neonatal resuscitation.

Neonatal Assessment and Stabilization

The steps taken to assess, stabilize, and transport an ill neonate in an optimal manner can make a significant difference in long-term outcomes. For this reason, it is crucial for CCTPs to recognize neonatal emergencies and know how to respond to them. The CCTP should optimally review the patient's relevant history, including prenatal issues, neonatal symptoms, vital signs (including BP), physical exam findings, chest or abdominal radiographs (if obtained), and laboratory values (including glucose) as soon as the transport need is identified, or at the very latest, on arrival at the referring institution. Communication among all health care providers remains critical throughout the transport to optimize care. Specifics regarding assessment and stabilization are described in the remainder of this section.

Risk Factors for Neonates

The risks for complications in neonates increase as birth weight and gestational age decrease. They also increase in term infants when additional complications such as maternal infection, diabetes, hypertension, or meconium are present. Low-birth-weight infants are at increased risk for hypoglycemia and hypothermia, and late-gestational-age babies are at increased risk for delayed transition and persistent pulmonary hypertension. Antepartum and intrapartum risk factors for complications are listed in **TABLE 23-3** and **TABLE 23-4**, respectively.

TABLE 23-3	Antepartum (Before Birth) Risk Factors
Multiple gestation	
Maternal age <16 years or >35 years	

Postterm (>42 weeks') gestation

Toxemia, hypertension, diabetes

Polyhydramnios (excessive amount of amniotic fluid)

Premature rupture of the membrane and fetal malformation

Inadequate prenatal care

History of perinatal morbidity or mortality

Maternal use of drugs/medications

Fetal anemia

Oligohydramnios (decreased volume of amniotic fluid during a pregnancy)

TABLE 23-4 Intrapartum (During Birth) Risk Factors

Premature labor

Rupture of membranes >24 hours before delivery

Abnormal presentation

Prolapsed cord

Chorioamnionitis

Meconium-stained amniotic fluid

Use of narcotics within 4 hours of delivery

Prolonged labor or precipitous delivery

Bleeding

Placenta previa

© Jones & Bartlett Learning.

Cord Clamping

Both the American Academy of Pediatrics (AAP) and the American College of Gynecologists (ACOG) recommend delayed cord clamping (30 to 60 seconds) for most vigorous term and preterm infants when feasible. This practice reduces the need for BP support and transfusion and may improve survival in the preterm infant. In addition, delayed cord clamping is associated with higher hematocrit and better iron levels in infancy. However, if the placental circulation is not intact, such as after abruptio placentae, bleeding placenta previa, bleeding vasa previa, or cord avulsion, the cord should be clamped immediately after birth. There is insufficient evidence at this time to recommend cord milking at delivery or an approach to cord clamping for neonates who require resuscitation at birth. It is important for the CCTP to inform the hospital whether delayed cord clamping was performed.

Apgar Score

The **Apgar score** is a standardized numeric expression of a baby's condition after birth **TABLE 23-5**. Traditionally, 1- and 5-minute scores are recorded, although extended scores (every 5 minutes, up to 20 minutes, if the score is less than 7) may need to be recorded if the newborn's condition remains depressed. Each of the five signs is awarded a score of 0, 1, or 2, with the total maximum score being 10.

TABLE 23-5 **The Apgar Score**

	Score		
Sign	**0**	**1**	**2**
Appearance (color)	Blue or pale	Body pink, extremities blue	Completely pink
Pulse (heart rate)	0	0–100	>100
Grimace (irritability)	No response	Grimace	Cries
Activity (muscle tone)	Limp	Some flexion	Active movement
Respirations	Absent	Slow or irregular	Strong cry

Data from Apgar V. A proposal for a new method of evaluation of the newborn infant. *Curr Res Anesth Analg*. 1953;32(4):260-267.

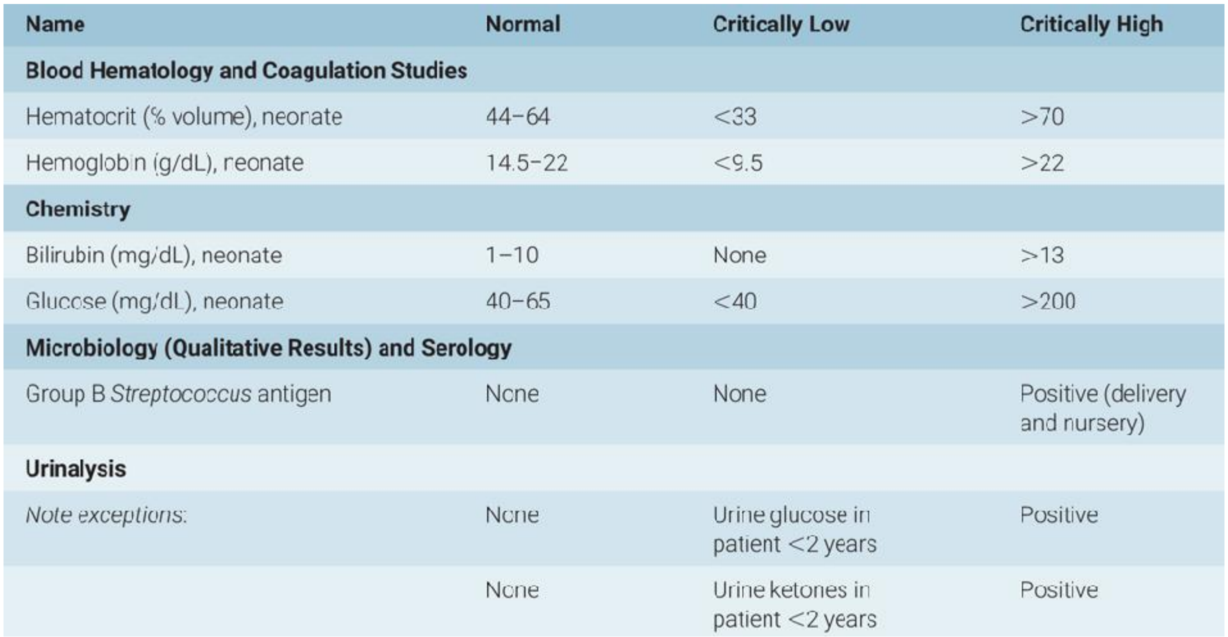
Description

The Apgar score is a limited indicator of the severity of hypoxic injury. The degree of correlation of the Apgar score with adverse neurologic outcome increases when the score remains 0 to 3 at 20 minutes. Factors that affect the Apgar score include physical maturity (Apgar scores are often lower in premature infants), maternal medication intake or narcotic use, and neuromuscular or cardiorespiratory conditions.

Laboratory Assessment

Neonatal laboratory values assist in managing a variety of critical conditions in these patients. Critical neonatal laboratory values are listed in **TABLE 23-6**.

TABLE 23-6 Critical Neonatal Lab Values



Name	Normal	Critically Low	Critically High
Blood Hematology and Coagulation Studies			
Hematocrit (% volume), neonate	44–64	<33	>70
Hemoglobin (g/dL), neonate	14.5–22	<9.5	>22
Chemistry			
Bilirubin (mg/dL), neonate	1–10	None	>13
Glucose (mg/dL), neonate	40–65	<40	>200
Microbiology (Qualitative Results) and Serology			
Group B *Streptococcus* antigen	None	None	Positive (delivery and nursery)

Description

Stabilization and Treatment

Stabilization of the neonate is needed if the patient has an acute airway obstruction, ineffective respiration, or insufficient cardiovascular circulation. As part of this care, the neonate must be evaluated for respiratory effort, heart rate, and color.

The first steps in stabilizing a neonate address airway management and ventilation. To optimize oxygenation and ventilation, ensure the neonate is in the appropriate sniffing position, and suction the neonate's mouth and nose if necessary. Continuous positive airway pressure (CPAP) is required if peripheral cyanosis is present despite adequate respiratory effort and a pulse rate greater than 100 beats/min. PPV is required if respiratory effort is inadequate, ineffective, or absent, or if the pulse rate is less than 100 beats/min. Gasping respirations usually indicate a significant problem and require the same interventions as absent respiratory effort or apnea.

Ventilations are provided at a rate of 40 to 60 breaths/min, with a tidal volume sufficient to expand the neonate's chest. Keep in mind that the physiologic tidal volume for a neonate is 5 to 7 mL/kg; hence, 15- to 20-mL breaths are needed for a term newborn. Resuscitation should begin with 21% oxygen (room air). PPV of newborns delivered prior to 35 weeks' gestation may begin with 21% to 30% oxygen. Free-flow oxygen may begin at a 30% oxygen level. The amount of oxygen delivered may be adjusted to meet the oxygen saturation target as determined by pulse oximetry by using the blender. Ensure that ventilation inflates and moves the chest. (See the section on neonatal resuscitation for more details.)

Intubation is no longer recommended for nonvigorous newborn infants born through meconium-stained amniotic fluid. Instead, the initial steps in the protocol for this condition should be performed and personnel trained in endotracheal intubation should be present at the delivery.

Use of a three-lead electronic cardiac monitor is a rapid and reliable method for continuously displaying the infant's heart rate. The pulse oximeter may have difficulty acquiring the signal if the patient has insufficient perfusion. Chest compressions are indicated if the neonate's pulse is less than 60 beats/min and shows no improvement despite effective and adequate PPV with T-piece/bag-mask ventilations (3 compressions followed by 1 breath, with 90 compressions and 30 breaths delivered each minute). Additional interventions—such as volume expansion (10 to 20 mL/kg bolus of normal saline), epinephrine (for persistent bradycardia of less than 60 beats/min despite optimal respirations and chest compressions), dextrose bolus (2 mL/kg $D_{10}W$ bolus for blood glucose levels less than 40 mg/dL), or sodium bicarbonate (for documented severe metabolic acidosis)—may be needed in some cases.

Special care needs to be taken when stabilizing and transporting a preterm neonate. Infants born before 34 weeks' gestation are at increased risk for bleeding into the brain (intraventricular hemorrhage). Avoiding rapid fluctuations in their BP, temperature, fluid volume, and pH status can help minimize this risk. Preterm infants who need oxygen therapy and mechanical ventilation are also at risk of long-term lung damage (bronchopulmonary dysplasia). Minimizing oxygen exposure and avoiding excessive pressures from assisted ventilation will decrease this risk. Of note, preterm infants (less than 37 0/7 weeks' gestation), including late-preterm infants (34 0/7 to 36 6/7 weeks' gestation), are also at increased risk of jaundice, dehydration, hypothermia, hypoglycemia, and sepsis.

It is important for the CCTP to communicate with the receiving facility as soon as possible when caring for a neonate. Important information includes relevant prenatal and birth history, vital signs, physical exam findings, resuscitation details, diagnostic studies done such as lab tests and radiographic results, relevant social issues, anticipated needs on arrival (eg, a ventilator), and estimated time of arrival.

Care of the neonate also includes emotional support of and communication with the neonate's parents. Encourage maternal bonding. Explain to the parents what is happening to their infant and which steps are being taken to optimize the infant's outcome. Do not provide false hope, and avoid discussing the neonate's chances of survival.

Neonatal Resuscitation

The neonate must be assessed using a systematic approach, as follows:

1. Begin with a rapid visual assessment of the newborn's overall appearance (muscle tone, cry), work of breathing (nasal flaring, reduced or absent respiratory effort), and abnormal breath sounds (grunting, stridor). Evaluation of circulation includes assessing for abnormal skin color (pallor, cyanosis, mottling) or bleeding. Determine whether the infant's clinical condition is life threatening. This evaluation can generally be completed within the first few seconds of the patient encounter.
2. Perform a rapid assessment to evaluate cardiopulmonary and neurologic function. This review includes measurement of vital signs and pulse oximetry.
3. Obtain a focused medical history and perform a thorough head-to-toe physical exam. Categorize the neonate's clinical condition by type and severity: respiratory, to include upper/lower airway obstruction, lung disease, or disorder of control of breathing; and cardiovascular, to include hypovolemia or cardiogenic shock.

The following is a modification of the neonatal resuscitation program and the pediatric advanced life support (PALS) protocol as applicable to newborns and neonates.

Primary Assessment: Airway, Breathing, and Circulation

The ABCs of neonatal resuscitation are as follows (after drying a wet newborn):

- **Airway.** Position and clear the airway.

- **Breathing.** Stimulate the infant to breathe and support breathing if insufficient.
- **Circulation.** Assess pulse rate and color; intervene as indicated.

The most important and effective actions in neonatal resuscitation are expanding the lungs and initiating ventilation, providing supplemental oxygen if indicated based on the CCTP's examination, and measuring pulse oximetry. In addition, it is essential to maintain normal body temperature in the neonate. The initial evaluation of the neonate begins with the evaluation of breathing, color, and pulse rate (counted for 6 seconds at the base of the cord or by auscultation and multiplied by 10).

It is essential to assess the neonate's airway for patency. In an infant who is cyanotic, ensure patency of the airway by positioning the head in the sniffing position; performing bulb suctioning of the mouth, followed by the nose if secretions are noted; and gently stimulating the infant. Tactile stimulation should be limited to drying an infant and rubbing the back and soles of the feet gently to avoid traumatic injury. It is important not to be too rough with the rubbing and to avoid slapping the infant, because these actions may lead to traumatic injury.

Look for movement of the chest and abdomen. Listen for breath sounds, and feel the movement of air at the nose and mouth. Upper airway obstruction presents as increased inspiratory effort with retractions, snoring or high-pitched stridor, and periods of absent breath sounds. Attempt to open and maintain the airway by use of the head tilt–chin lift or jaw-thrust maneuver. Suction the nose and pharynx. Intubation may be required if these measures do not work.

A respiratory rate of greater than 60 breaths/min is abnormal at any age in a child. A decreasing or irregular respiratory rate may suggest worsening of the clinical condition, especially if associated with a deterioration in the level of consciousness. A decreased respiratory rate or an irregular respiratory rate in an acutely ill child is an ominous clinical sign because it often signals impending cardiopulmonary arrest.

Alteration in neurologic function in infants may be caused by conditions other than cerebral hypoxia. Some drugs and metabolic conditions, such as rising ammonia from an inborn error of metabolism or increased intracranial pressure, may cause neurologic signs. Careful evaluation of pallor, mottling, and cyanosis may identify inadequate oxygen delivery to the tissues. **Acrocyanosis** (blue discoloration of hands and feet) is often seen in healthy newborns; unlike **central cyanosis**, it is not associated with hypoxia.

In an emergency situation where it may not be possible to weigh the infant or child, CCTPs should be familiar with the use of a length-based/color-coded resuscitation tape (eg, the Broselow tape) to estimate body weight based on the child's crown-to-heel length **FIGURE 23-3**. Use of this tape is helpful because most neonatal and pediatric (up to 88 pounds [40 kg]) drug doses are based on body weight. Such a tape can also help the CCTP determine the appropriate size of resuscitation supplies for the patient. The sizes for pediatric supplies are organized and listed according to the length-based/color-coded classification scheme.

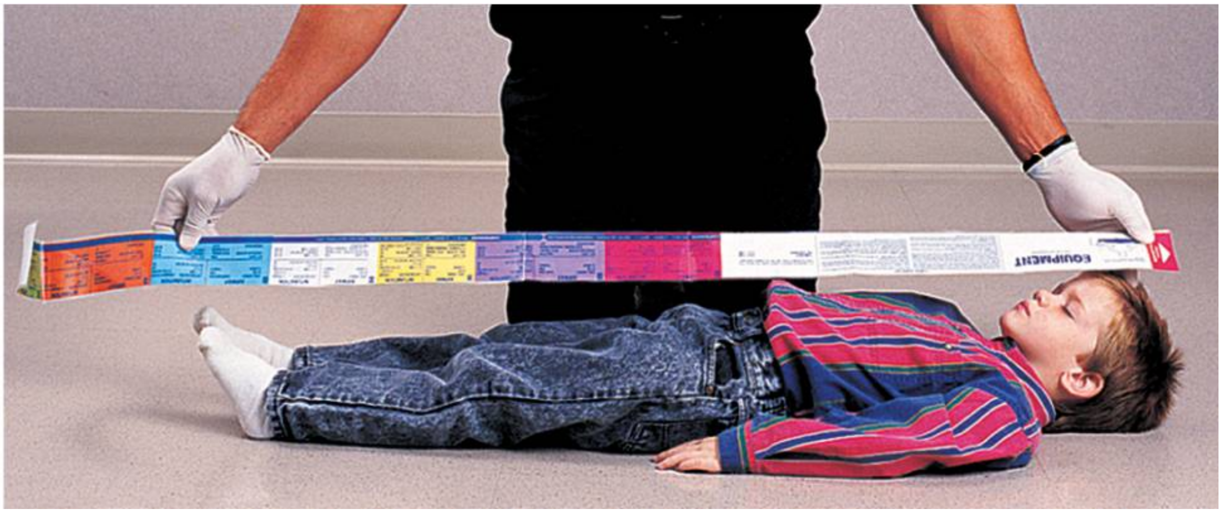

FIGURE 23-3 Use of a length-based resuscitation tape is one method to estimate a child's weight and identify the correct size for pediatric equipment and appropriate medication doses. While a child is pictured here, the tape can also be used for an infant.

Airway and Breathing Management

Free-Flow Oxygen

Providing free-flow oxygen to a cyanotic newborn with inadequate respiratory effort is of little or no value and merely delays appropriate treatment. For the older neonate, however, free-flow oxygen may be used. If oxygen needs to be provided, it should be warmed and humidified if it needs to be provided for more than a few minutes.

If PPV is not indicated (ie, if the neonate has a pulse rate greater than 100 beats/min and adequate respiratory effort), oxygen can initially be delivered through an oxygen mask held close to the infant's face. Alternatively, if a flow-inflating bag is set up, the CCTP can deliver oxygen by holding the mask close to the infant's face. If a self-inflating bag is connected to an oxygen source, the CCTP can hold the oxygen reservoir close to the infant's face to provide oxygen, or the CCTP can disconnect the oxygen tubing from the self-inflating bag and hold the tubing within a hand cupped loosely over the mouth and nose to facilitate delivery of supplemental oxygen. Holding the mask over the neonate's face without squeezing the bag does not deliver oxygen from a self-inflating bag. The oxygen flow rate should be less than or equal to 5 L/min to minimize hypothermia.

Remember that a level of 5 g/dL of deoxygenated hemoglobin must be reached before clinical cyanosis is observed. A severely anemic hypoxic neonate will be pale, but not cyanotic.

Continuous Positive Airway Pressure

CPAP is the first-line option for ensuring adequate ventilation of a newborn. If the newborn is cyanotic or pale, provide supplemental oxygen using positive end-expiratory pressure (PEEP) of 4 to 6 cm H_2O using the T-piece or the flow-inflating bag. Ideally, resuscitation should be initiated with room air. Use an oxygen saturation monitor (pulse oximeter) to adjust the amount of oxygen to the target range appropriate for the patient's condition.

Studies have demonstrated that even short exposure to supplemental oxygen may be associated with adverse oxidant stress in the neonate, both directly to the lungs and indirectly to the premature neonate's eyes. Thus, CCTPs should avoid unnecessary administration of supplemental oxygen to premature infants because this practice can lead to blindness and exacerbate lung disease.

During resuscitation of the newborn, follow the chart included in the latest Neonatal Resuscitation Program guidelines to titrate oxygen to targeted preductal (right-hand) saturations **TABLE 23-7**. After the immediate newborn period, a premature infant's oxygen saturation should be maintained at 88% to 92%, and a term infant's oxygen saturation should be maintained at 95% to 98% saturation.

Oral Airways

Oral airways are rarely used in neonates, but can be lifesaving if airway obstruction leads to respiratory failure. Bilateral **choanal atresia** (a bony or membranous obstruction at the back of the nose that prevents airflow) can be rapidly fatal but usually improves with placement of an oral airway (or a gloved finger until an adequate-size oral airway is located). **Pierre Robin syndrome** comprises a series of developmental anomalies, including a small chin and posteriorly positioned tongue that frequently leads to airway obstruction.

Positioning the patient prone (chest down) may relieve this obstruction. If not, an oral airway should be placed.

Positive-Pressure Ventilation Using T-Piece or Bag-Mask Ventilation

Signs of respiratory distress that suggest a possible need for PPV include gasping or periodic breathing, apnea, inadequate respiratory effort, intercostal retractions (sucking in between the ribs), nasal flaring, and grunting on expiration, or persistent pulse rate of less than 100 beats/min (which constitutes bradycardia in newborns) after clearing the airway, maintaining appropriate head position, relieving any obstructions, and providing stimulation. Respiratory distress occurs in approximately 8 in every 1,000 live births and accounts for nearly 15% of neonatal deaths. PPV is also required when the neonate exhibits persistent central cyanosis despite breathing 100% oxygen.

Adequate PPV with oxygen requires the use of appropriate-size equipment with techniques modified for the unique needs of the neonate. The face mask needs to provide an airtight seal, fitting over the infant's mouth and nose, and extending down to the chin but not over the eyes **FIGURE 23-4**. The infant needs to have a patent airway, cleared of secretions, with the neck slightly extended in the sniffing position **FIGURE 23-5**. The first few breaths of a neonate after birth frequently require higher pressures (sometimes as high as 30 cm H_2O, or even higher for very brief periods of time) because the lungs are not yet expanded and are still filled with fluid. To deliver these initial breaths, the CCTP may need to disable the pop-off valve (usually set by the manufacturer at 30 to 40 cm H_2O) on the bag. Subsequent breaths should be delivered with sufficient pressure to result in visible but not excessive chest rise. Assuming the newborn has normal lungs, the neonate should appear to be taking an easy breath, with a pressure of about 15 to 20 cm H_2O.

Three devices may be used to deliver PPV to a neonate. The first device is a self-inflating bag with an oxygen reservoir **FIGURE 23-6A**. With this method, an oxygen source is not necessary to provide PPV but is needed to provide supplemental oxygen. The second device is a flow-inflating bag, which requires a gas source to provide PPV **FIGURE 23-6B**. The third device is a T-piece resuscitator, which also requires a pressure source of air/oxygen; this device minimizes the risk of excessive pressures, pneumothorax, and lung injury in the neonate **FIGURE 23-6C**. The T-piece resuscitator, if available, is preferred for providing PPV to a newborn, especially if the newborn is preterm. Regardless of which piece of equipment is used, adequate pressure to achieve visible chest movement is necessary to ensure adequate ventilation. Excessive chest movement increases the risk of pneumothorax and lung injury, so it should be avoided.

CCTPs should ensure that they are familiar with the available equipment in advance and that this equipment is in working order. CCTPs will most likely use a self-inflating bag for ventilation of neonates. When providing ventilator assistance, it is important to use the infant size (240 mL) bag if available. Since the tidal volume of a neonate is only 5 to 7 mL/kg, only one-tenth the volume of a 240-mL bag is used for each breath. If a neonatal bag is not available and the infant has severe respiratory distress, apnea, or bradycardia, a bag designed for adults or older children (750 mL or greater volume) may be used if the delivered breath size is kept appropriately small. In this situation, it is even more critical to monitor chest rise to avoid an excessive volume of delivered breaths. **FIGURE 23-7** shows the algorithm for treating a distressed newborn.

Description

The most common reasons for ineffective bag-mask ventilation are inadequate mask seal and incorrect head position. Other causes, such as mucus plugging, pneumothorax, equipment malfunction, or insufficient pressure, need to be considered as well.

The correct timing for delivering breaths in a neonate is 40 to 60 breaths/min. It is easy to deliver breaths at a much higher rate, which can increase risks such as hypocapnia, air trapping, and pneumothorax. Counting “breathe–two–three–breathe–two–three” as you ventilate (give a breath on “breathe” and release while you say “two–three”) can help with timing. PPV should continue as long as the infant’s pulse rate remains less than 100 beats/min or the respiratory effort is ineffective. If prolonged PPV is needed, using a pressure manometer is important to help monitor the pressures delivered and minimize excessive pressures (usually less than 25 cm H_2O pressure in term infants, but even lower pressure in preterm infants).

Supplemental Oxygen

Initiating neonatal resuscitation with 100% oxygen is no longer recommended. As noted earlier, resuscitation (PPV) of newborns born at 35 weeks' gestation or later begins with 21% oxygen. In contrast, PPV of newborns delivered prior to 35 weeks' gestation may begin with 21% to 30% oxygen. A recent meta-analysis suggests that resuscitation initiated with room air may result in increased survival as compared with resuscitation initiated with 100% oxygen. The 2020 American Heart Association guidelines for resuscitation recommend a target range of oxygen saturation for both preterm and full-term infants that is incorporated into the neonatal resuscitation algorithm. These guidelines are based on the preductal oxygen saturations measured in healthy term babies following vaginal birth. A pulse oximeter is used to measure the preductal oxygen saturation (right hand). In turn, supplemental oxygen should be titrated using a blender based on these readings.

Ventilation can be initiated with either room air or blended oxygen, with the oxygen concentration then being titrated to achieve the target oxygen saturation as measured by a pulse oximeter. If the newborn's heart rate increases after 15 seconds of PPV, continue PPV for another 15 seconds and reassess the heart rate. If the heart rate is not increasing but the newborn's chest is moving, continue PPV for another 15 seconds before reassessing the heart rate. If the heart rate is not increasing and the chest wall is not moving, administer ventilation corrective steps (Mask adjustment, Reposition airway, Suction mouth and nose, Open mouth, Pressure increase, Airway alternative [MR SOPA]) until the newborn's chest moves with ventilation. Reassess the heart rate after 30 seconds to evaluate its stability. If the heart rate remains less than 60 beats/min despite ventilation corrective steps, consider using an alternative airway, such as an endotracheal (ET) tube or laryngeal mask airway. The laryngeal mask airway is available in one size for newborns and can be used for those weighing more than 1,500 grams. For newborns weighing less than 1,500 grams, intubation remains the only choice if an alternative airway is needed. If no improvement is noted in the heart rate but the neonate's chest is moving with PPV, begin 100% oxygen and chest compressions. Chest compressions are not indicated until adequate ventilation has been provided.

Throughout the care process, continue to monitor the effectiveness of ventilation and keep the infant warm. Ventilation of the lungs is the single most important and effective step in cardiopulmonary resuscitation of the compromised newborn. Signs of effective ventilation include rapid rise in heart rate, improvement in color and tone, audible breath sounds by auscultation, and visible chest rise.

TABLE 23-8 lists equipment and medications needed in preparation for neonatal resuscitation.

TABLE 23-8	**Preparation of Area for Neonatal Resuscitation**
Resuscitation equipment and supplies	• Suction equipment • Bulb syringe, mechanical suction and tubing, 5F or 6F suction catheters • 8F feeding tube and 20-mL syringe
Bag-mask/T-piece resuscitator equipment	• Device for delivering PPV, capable of delivering 90% to 100% oxygen • Face masks, neonatal and premature infant size (cushioned-rim masks preferred) • Oxygen source with flowmeter (flow rate up to 10 L/min)
Intubation equipment	• Laryngoscope with straight blades, size 0 (preterm) and size 1 (term) • Extra bulb, batteries for laryngoscope • Endotracheal tubes, sizes 2.5, 3.0, 3.5, and 4.0 • Stylet (optional) • Scissors and tape for securing endotracheal tube • CO_2 detectors (optional)

	• Laryngeal mask airway (optional): effective for ventilating newborns weighing more than 4 lb (2,000 g) or ≥34 weeks' gestation
Medications	• Epinephrine 0.1 mg/mL, 3- or 10-mL ampules • Isotonic crystalloid (normal saline or lactated Ringer solution), 100- or 250-mL bag • Sodium bicarbonate 4.2% (5 mEq/10 mL) • Dextrose 10%, 250 mL • Naloxone is no longer recommended for the initial resuscitation of newborns with respiratory depression. Heart rate and oxygenation should be restored by supporting ventilation.
Umbilical catheterization equipment	• Sterile gloves • Scalpel or scissors • Antiseptic solution • Umbilical tape • Umbilical catheters, sizes 3.5F and 5F (a sterile 3.5F feeding tube can be used in an emergency) • Three-way stopcock • Syringes, sizes 1, 3, 5, 10, 20, and 50 mL • Needles, sizes 25, 21, and 18 gauge
Miscellaneous	• Gloves and appropriate BSI protection • Radiant warmer or other heat source • Firm, padded resuscitation surface • Clock with second hand, timer optional • Towels, linens • Stethoscope, neonatal or pediatric preferred • Cardiac monitor or saturation monitor • Oropharyngeal airway (0, 00, and 000 sizes or 30-, 40-, and 50-mm long)

Abbreviations: BSI, body substance isolation; PPV, positive-pressure ventilation
Data from American Academy of Pediatrics. *Textbook of Neonatal Resuscitation*. 8th ed. Dallas, TX: American Heart Association; 2021.

Intubation

Most neonatal resuscitations can be successfully completed with bag-mask ventilation. However, intubation is indicated in the following circumstances:

- Congenital **diaphragmatic hernia** (a congenital defect in which the abdominal organs herniate into the chest cavity through an opening in the diaphragm) is suspected and respiratory support is indicated.
- The infant is not responding to bag-mask ventilation and 100% oxygen. Intubation is strongly recommended prior to beginning chest compressions. If intubation is not successful or feasible, a laryngeal mask may be used.
- Prolonged PPV is needed.

Before beginning to intubate the neonate, ensure that the appropriate equipment is at hand. Use a straight blade of size #1 for a term infant and of size #0 for a preterm infant. Endotracheal tubes for neonates are available in sizes ranging from 2.5 to 4.0 mm **TABLE 23-9**. Again, a length-based/color-coded resuscitation tape or Broselow tape can be used to estimate the appropriate ET tube size. A stylet may be used to provide rigidity to the ET tube. If a stylet is used, it is imperative to secure it in its position (bending it over at the top of the ET tube so it cannot advance) and to not allow it to extend beyond the ET tube to minimize the risk of tracheal perforation.

TABLE 23-9 **Neonatal Endotracheal Tube Sizes**

Size	Recommended Age (weeks)
2.5	<28
3.0	28–34
3.5	34–38

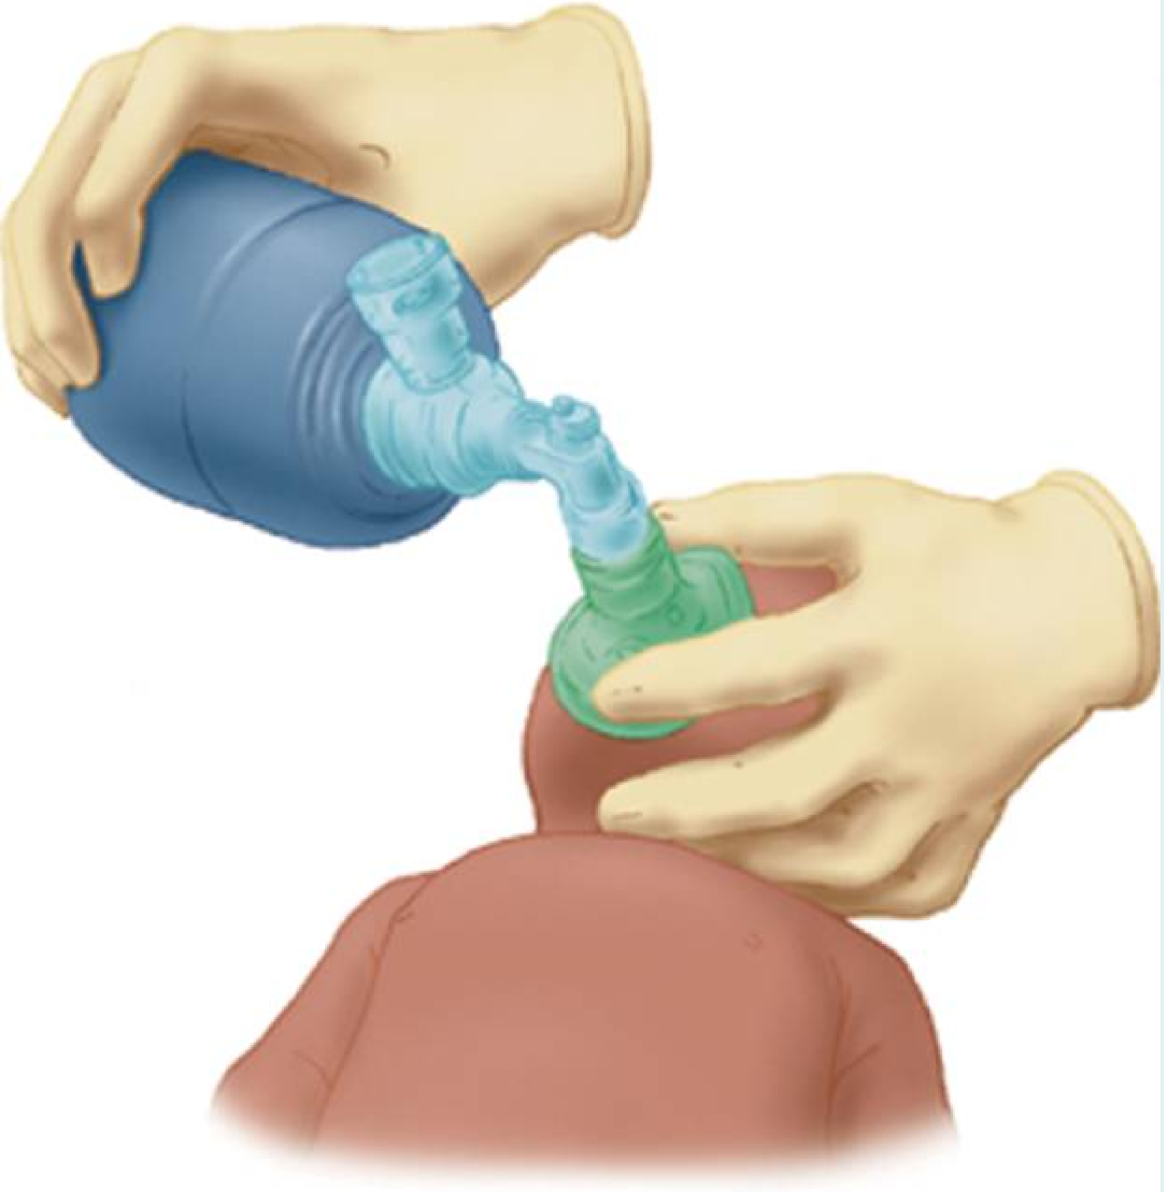
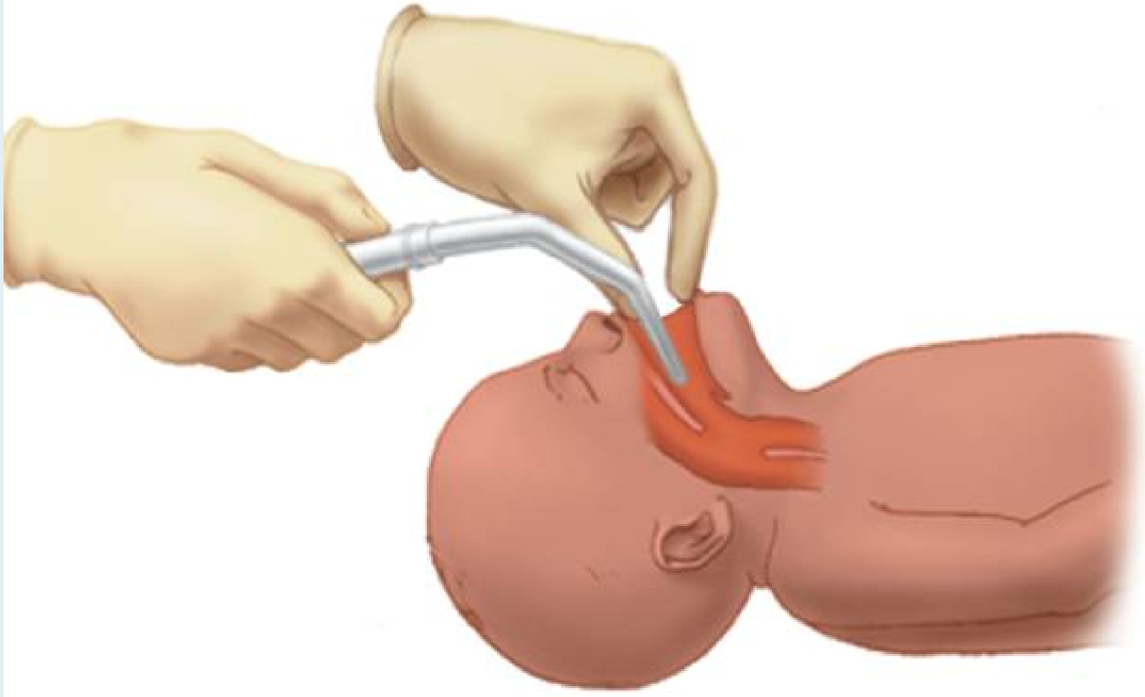
Skill Drill 23-1 shows intubation of the neonate, which is discussed in the following steps:

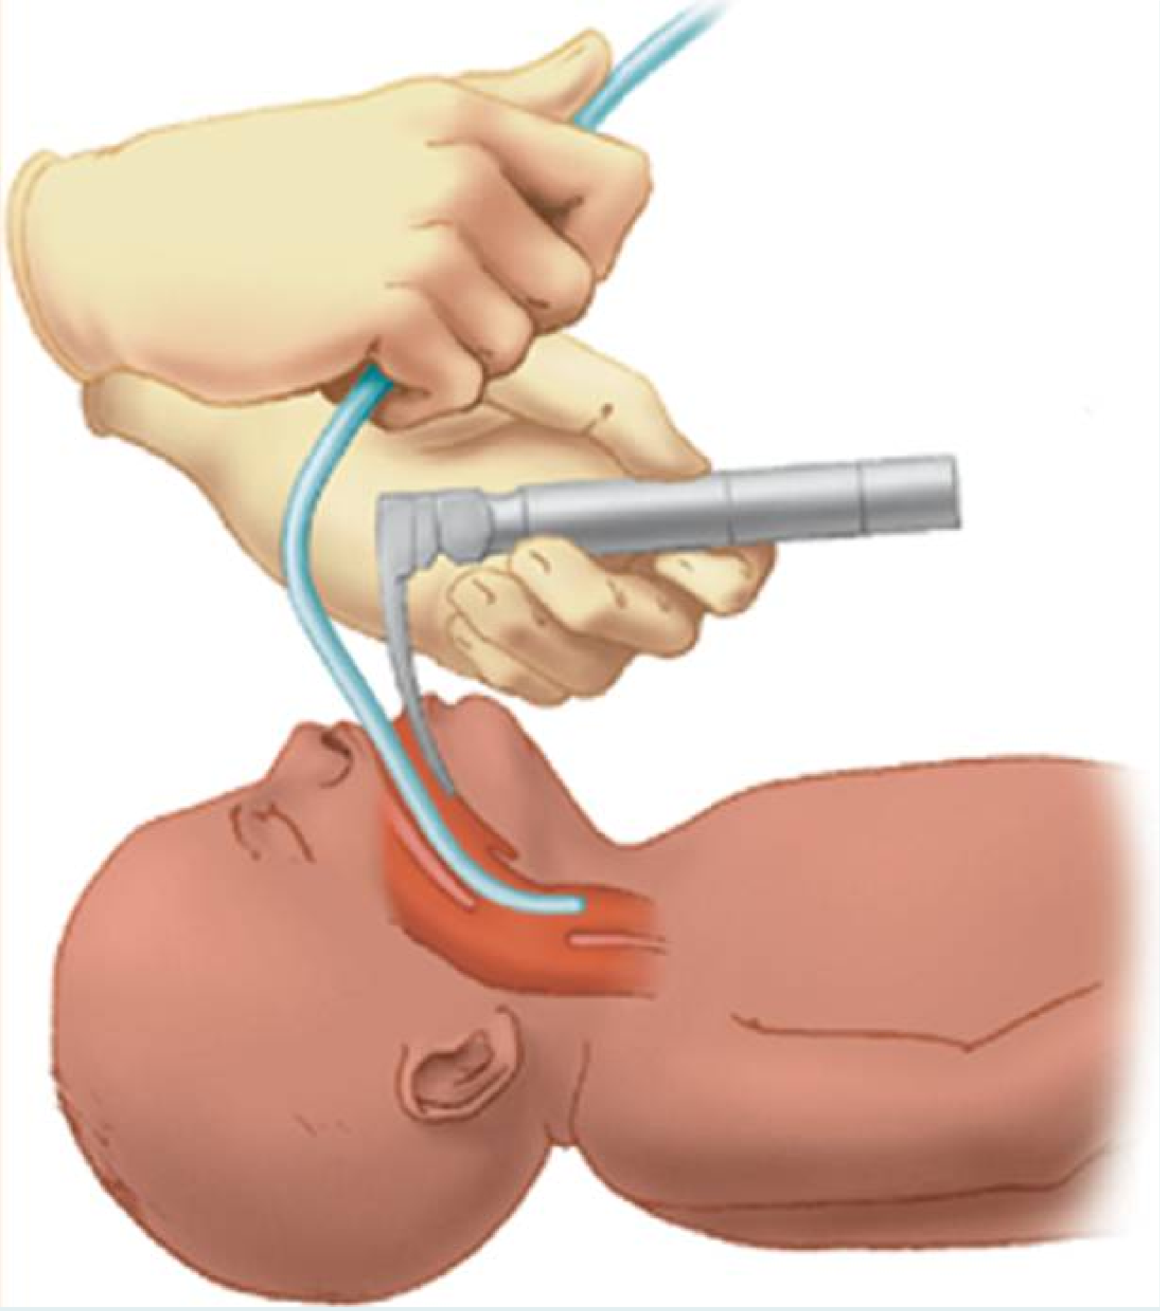
SKILL DRILL 23-1 Intubation of a Neonate



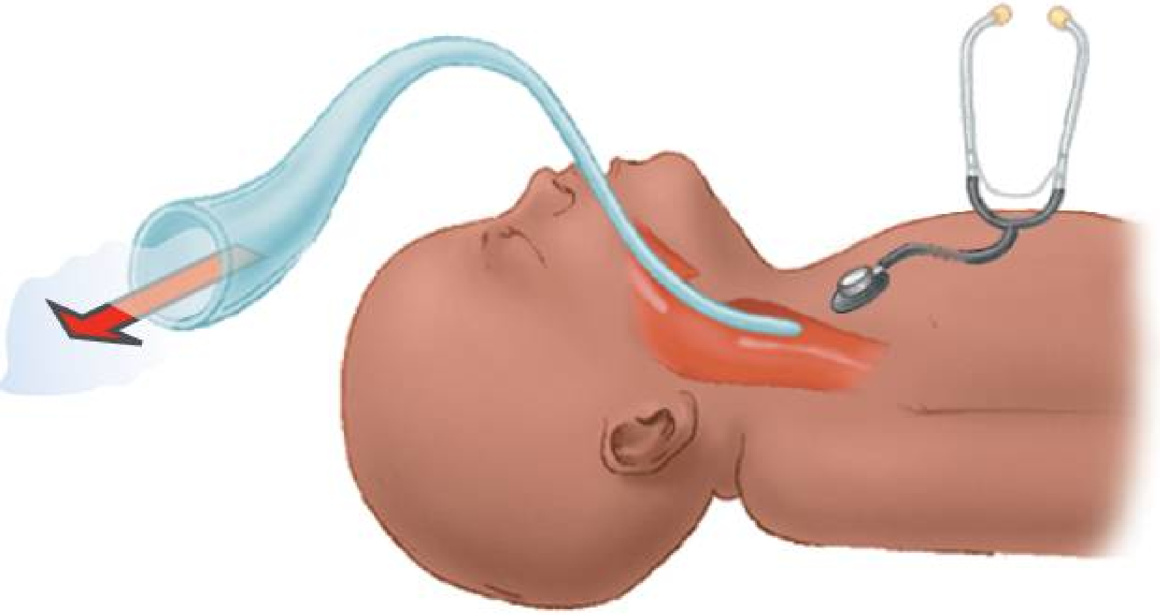
Step 1
Preoxygenate the infant by bag-mask ventilation with 100% supplemental oxygen.



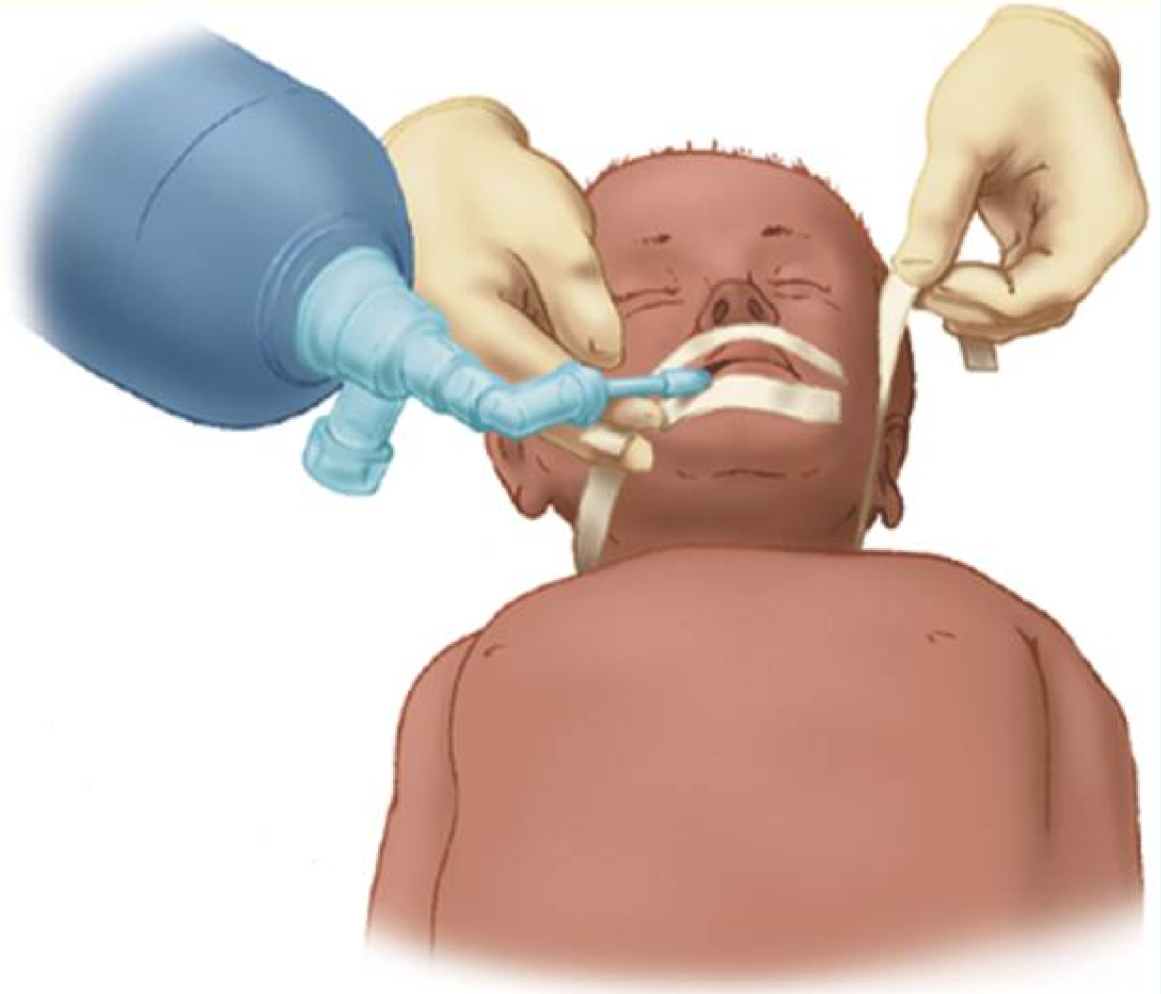
Step 2
Suction the oropharynx. Provide bag-mask ventilation if bradycardia results.



Step 3
Place the laryngoscope blade in the oropharynx. Visualize the vocal cords. Place the ET tube between the vocal cords until the black line on the tube is at the level of the cords.



Step 4
Confirm placement. Observe chest rise, auscultate laterally and high on the chest, note the absence of significant air sounds over the stomach, note mist in the ET tube, and use a CO_2 detector.



Step 5
Tape the ET tube in place. Monitor the neonate closely for complications.

© Jones & Bartlett Learning.

1. Ensure the neonate is preoxygenated by bag-mask/T-piece ventilation with oxygen as needed to maintain adequate saturation prior to an intubation attempt **STEP 1**.
2. Suction the oropharynx to ensure removal of secretions if unable to visualize the vocal cords **STEP 2**. This is a vagal stimulus, so pay close attention to the infant’s pulse rate; bag-mask ventilation may again be needed prior to the intubation attempt if bradycardia occurs.

3. Place the laryngoscope blade in the oropharynx and then visualize the vocal cords, keeping in mind that the vocal cords are more cephalad and anterior in neonates relative to adults **STEP 3**. Take care to avoid applying torque to the blade, which increases the risk of trauma. Place the ET tube between the vocal cords until the black line on the tube is at the level of the cords. A general rule of thumb is that the insertion depth for the ET tube is the nasal-tragus length. The following formula may also be used to calculate the initial tip-to-lip depth for the tube:

   $$\text{Weight (in kg)} + 6$$

   Insert the laryngeal mask airway until resistance is felt.
   In an extremely low-birth-weight baby (less than 2 pounds [1,000 g]), the ET tube may need be advanced to only 6.5 to 7 cm at the lip, compared to 9 to 10 cm for a full-term newborn. Intubation attempts should be limited to 30 seconds, followed by bag-mask ventilation if unsuccessful or if significant bradycardia develops.
4. Confirm placement by observing chest rise when applying positive pressure through the ET tube, auscultating laterally and high on the chest, confirming the absence of significant air sounds over the stomach, noting mist in the ET tube (mist will be seen when the patient exhales through the tube from condensation of humidified air leaving the lungs), and observing clinical improvement of the patient **STEP 4**. A CO_2 detector should be used if available.
5. Tape the ET/laryngeal mask airway tube in place on the patient’s face to minimize the risk of the tube becoming dislodged **STEP 5**. Monitor the infant closely for complications such as tube dislodgement, tube occlusion by mucus plugging, or pneumothorax.

Complications of ET tube placement may include oropharyngeal or tracheal perforation, esophageal intubation with subsequent persistent hypoxia, and right main stem intubation that can lead to atelectasis, persistent hypoxia, and pneumothorax. These risks can be minimized by ensuring optimal placement of the laryngoscope blade and by carefully noting how far the ET tube is being advanced.

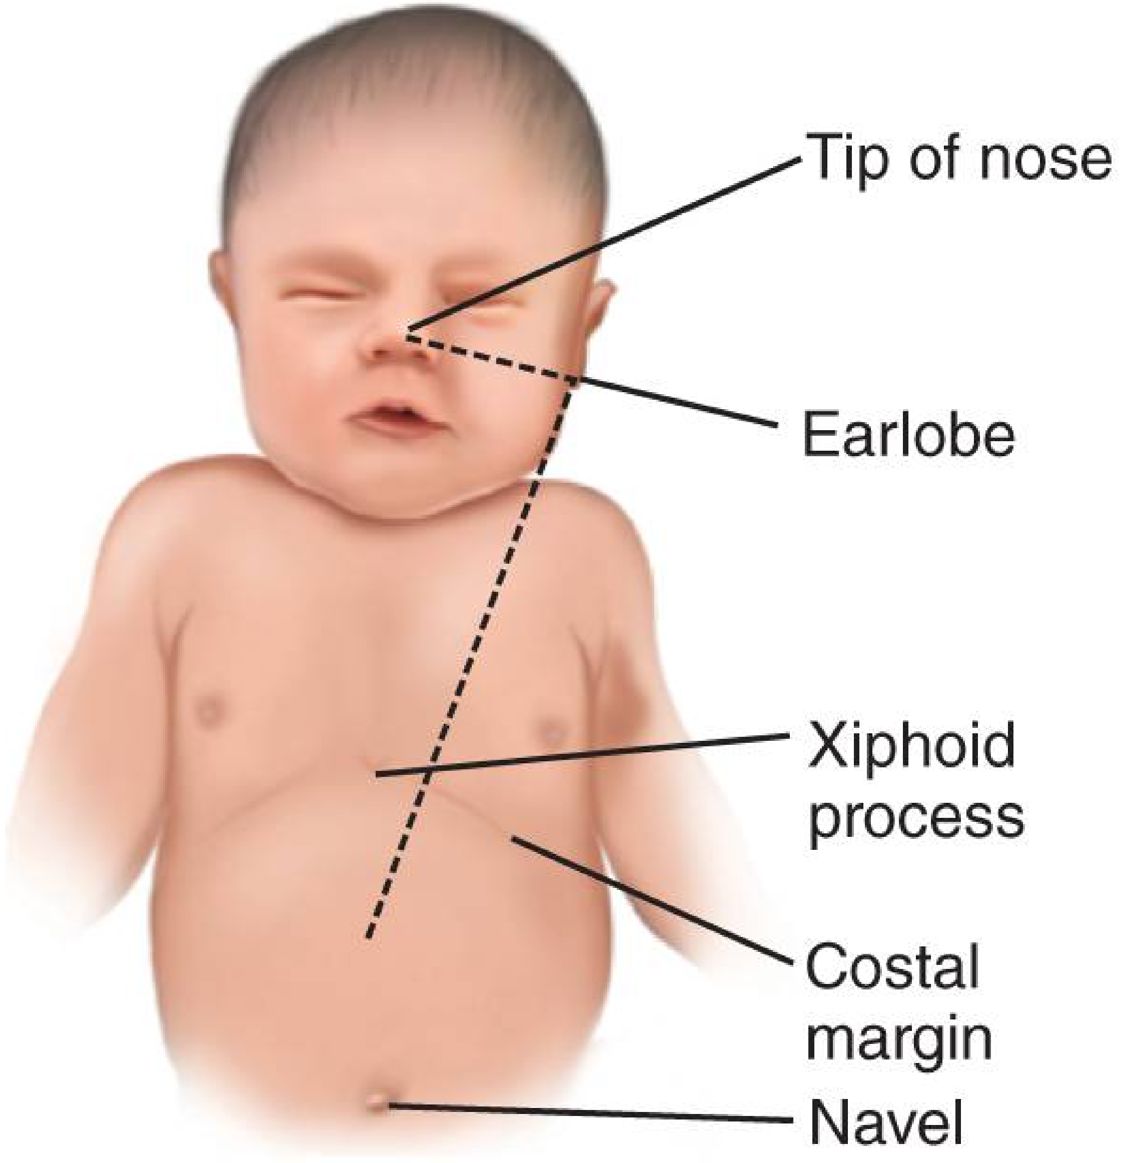
Premedication is often not needed when intubating depressed neonates. Consider giving atropine to help avoid vagal-induced bradycardia. Administer sedation if agitation is present. Avoid paralytics since neonatal airways are very small and may be difficult to maintain once the neonate is paralyzed.

Gastric Decompression

Gastric decompression using an orogastric tube is indicated for infants receiving prolonged bag-mask ventilation (more than 5 to 10 minutes) to counteract abdominal distention that is impeding ventilation, or in the presence of a known or suspected diaphragmatic hernia. Many diaphragmatic hernias are diagnosed prenatally by using routine ultrasonography. They are suspected clinically if the following signs are noted: decreased breath sounds (90% of diaphragmatic hernias are left-side), a scaphoid (concave) abdomen due to the presence of abdominal contents in the chest, and increased work of breathing.

Skill Drill 23-2 shows neonatal orogastric tube placement, which is discussed in the following steps:

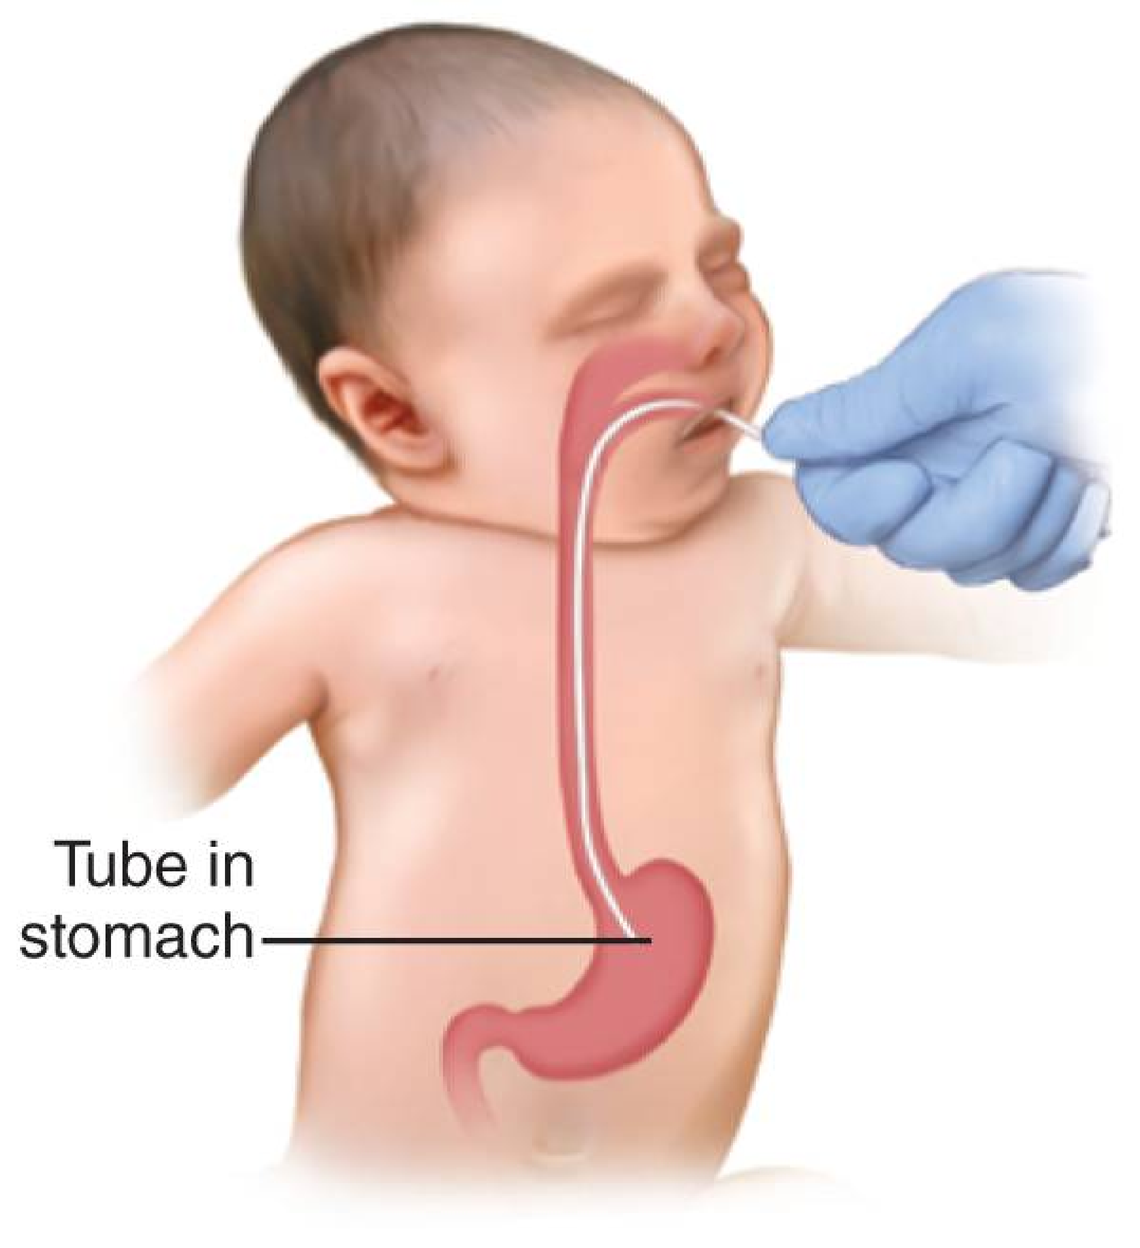
SKILL DRILL 23-2 Inserting an Orogastric Tube in the Neonate



Tip of nose
Earlobe
Xiphoid process
Costal margin
Navel

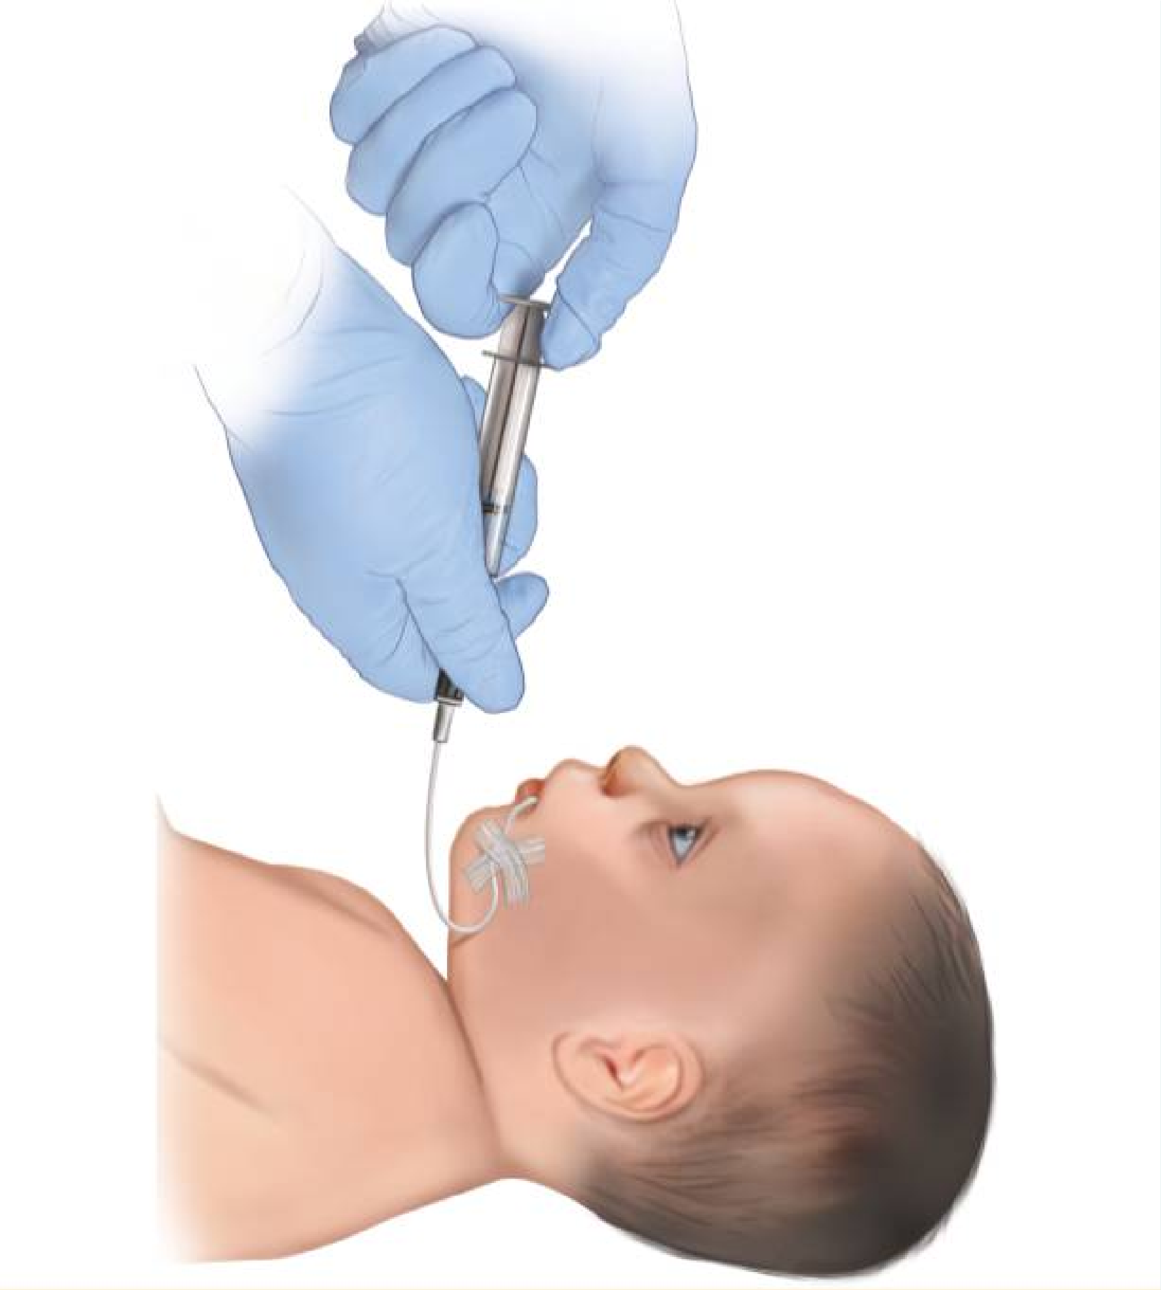
Step 1

Measure for correct depth—from the bottom of the ear lobe to the tip of the nose to halfway between the xiphoid process (lower tip of the sternum) and the umbilicus.



Tube in stomach

Step 2
Insert the tube to the appropriate depth.



Step 3
Remove the gastric contents with a 20-mL syringe. Tape the tube to the neonate’s cheek. Remove the syringe from the feeding tube to allow air to vent from the stomach.

© Jones & Bartlett Learning.

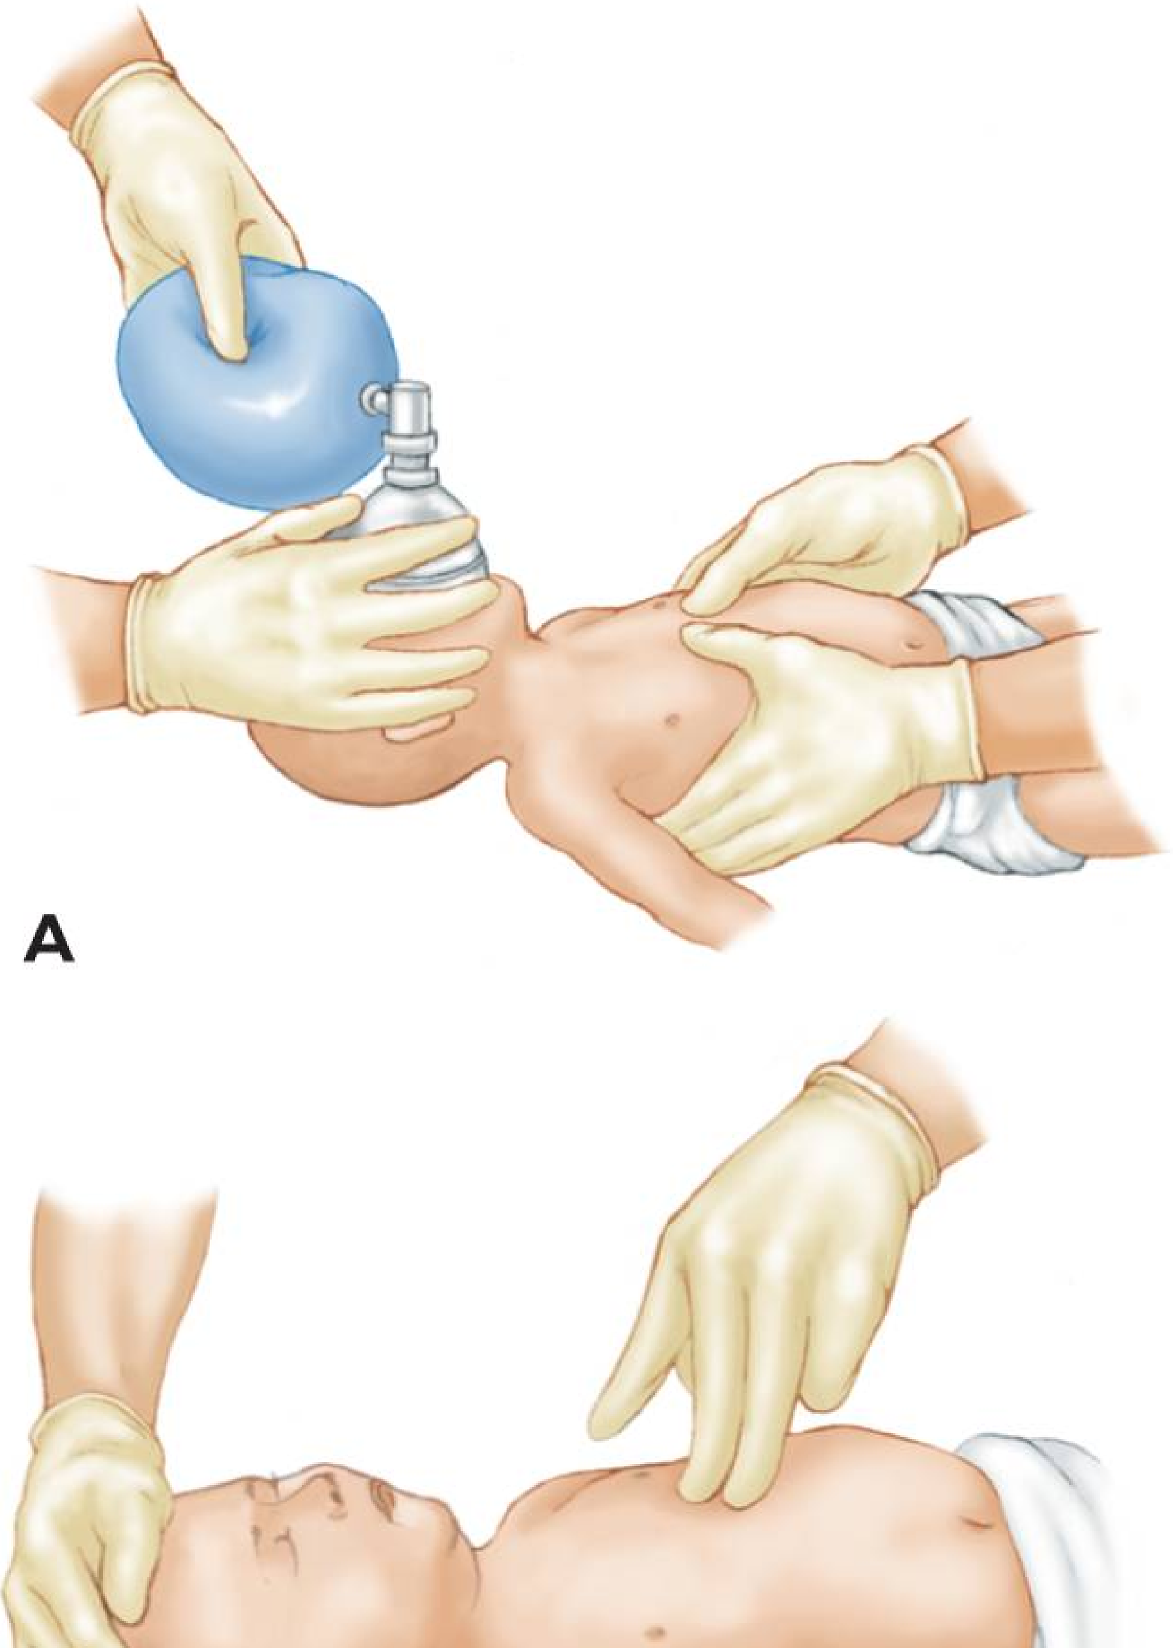
1. To determine the length of tube to insert, use an 8F feeding tube and measure the length from the bottom of the ear lobe to the tip

of the nose to halfway between the xiphoid process (lower tip of the sternum) and the umbilicus **STEP 1**.

2. Insert the tube through the mouth to the appropriate depth **STEP 2**.
3. Attach a 20-gauge syringe and suction the stomach contents **STEP 3**. Tape the tube to the neonate's cheek. Remove the syringe from the feeding tube to allow venting of air from the stomach, and intermittently suction the feeding tube.

Circulation

Chest compressions are indicated if the neonate's heart rate remains less than 60 beats/min despite management efforts related to positioning, clearing the airway, drying and stimulation, and 30 seconds of effective PPV. Two techniques can be used to perform chest compressions: the two-thumbs, encircling-hands technique and the two-finger technique. In the two-thumbs, encircling-hands technique (the recommended technique), two thumbs are placed side by side over the sternum between the nipples, and the hands encircle the torso **FIGURE 23-8A**. The chest should be compressed one-third the anterior-posterior diameter of the chest. In the two-finger technique, the tips of two fingers are placed over the sternum between the nipples, and the sternum is compressed one-third the anterior-posterior diameter of the chest **FIGURE 23-8B**. This method is used only if the provider cannot access the newborn in such a way as to perform the two-thumbs, encircling-hands technique. The two-thumbs, encircling-hands technique is preferred because it may generate higher peak systolic and coronary perfusion pressure than the two-finger technique. This technique may be performed from the head of the bed once the airway has been secured when access to the umbilicus is required during insertion of an umbilical catheter. If the infant is intubated, the two-thumbs, encircling-hands technique can be used by the CCTP who is standing at the infant's head.



A

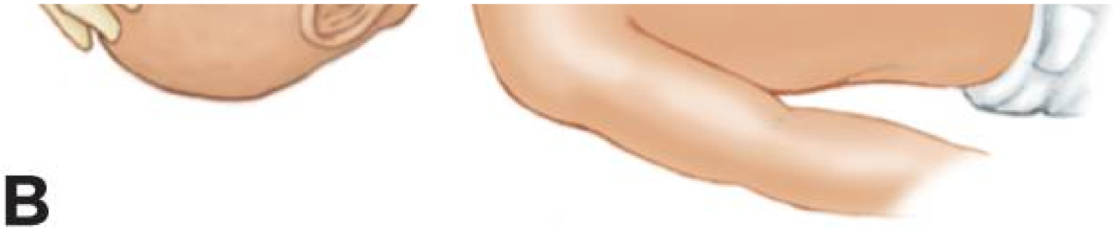


FIGURE 23-8 Chest compressions in the neonate. **A.** The two-thumbs, encircling-hands technique; this is the recommended method. **B.** The two-finger technique; use this method only if unable to use the two-thumbs, encircling-hands technique.

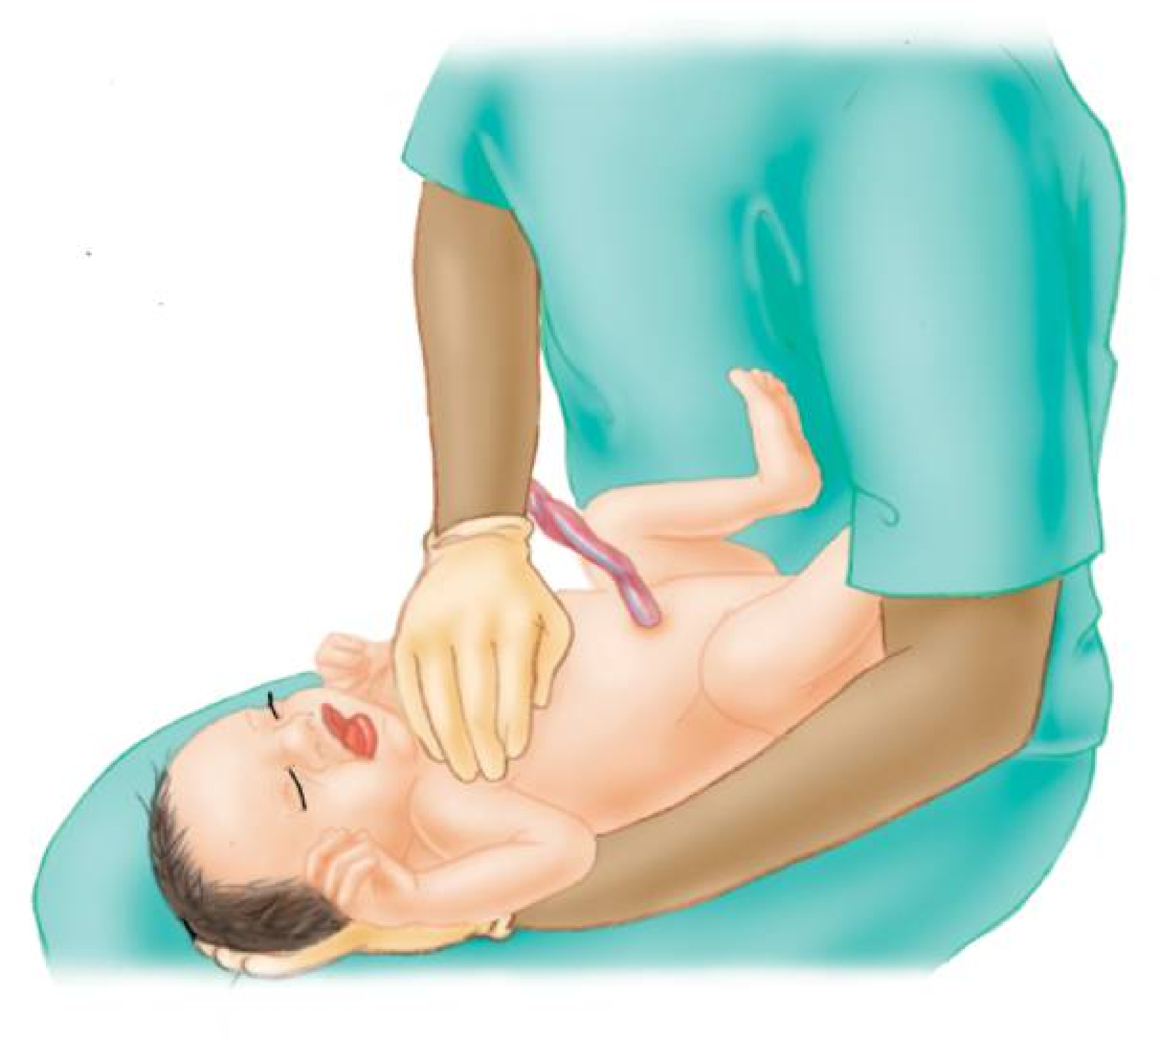
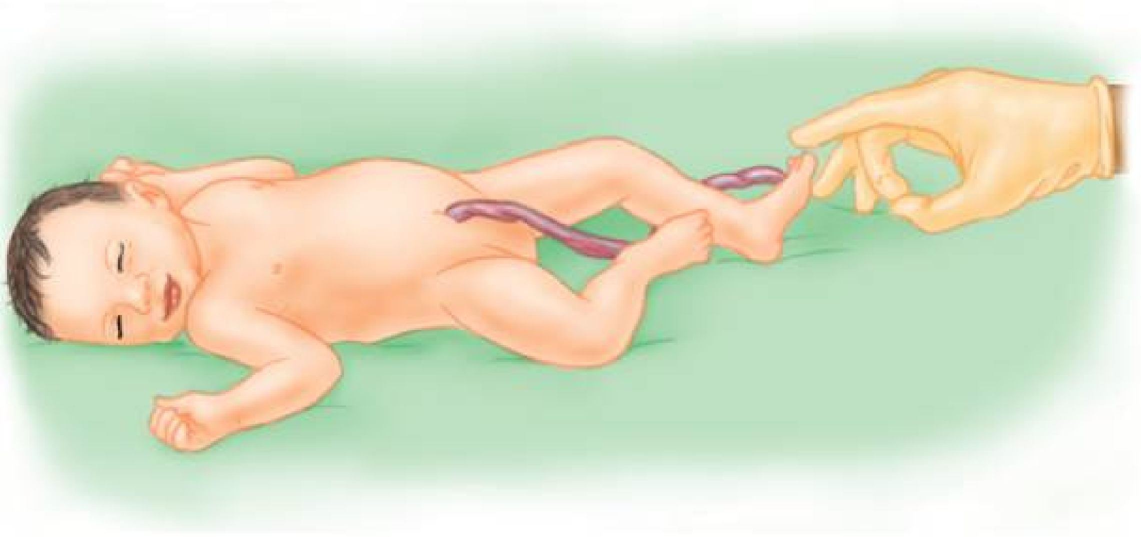
Description Description

Skill Drill 23-3 reviews the steps for resuscitating a neonate, which are listed here:

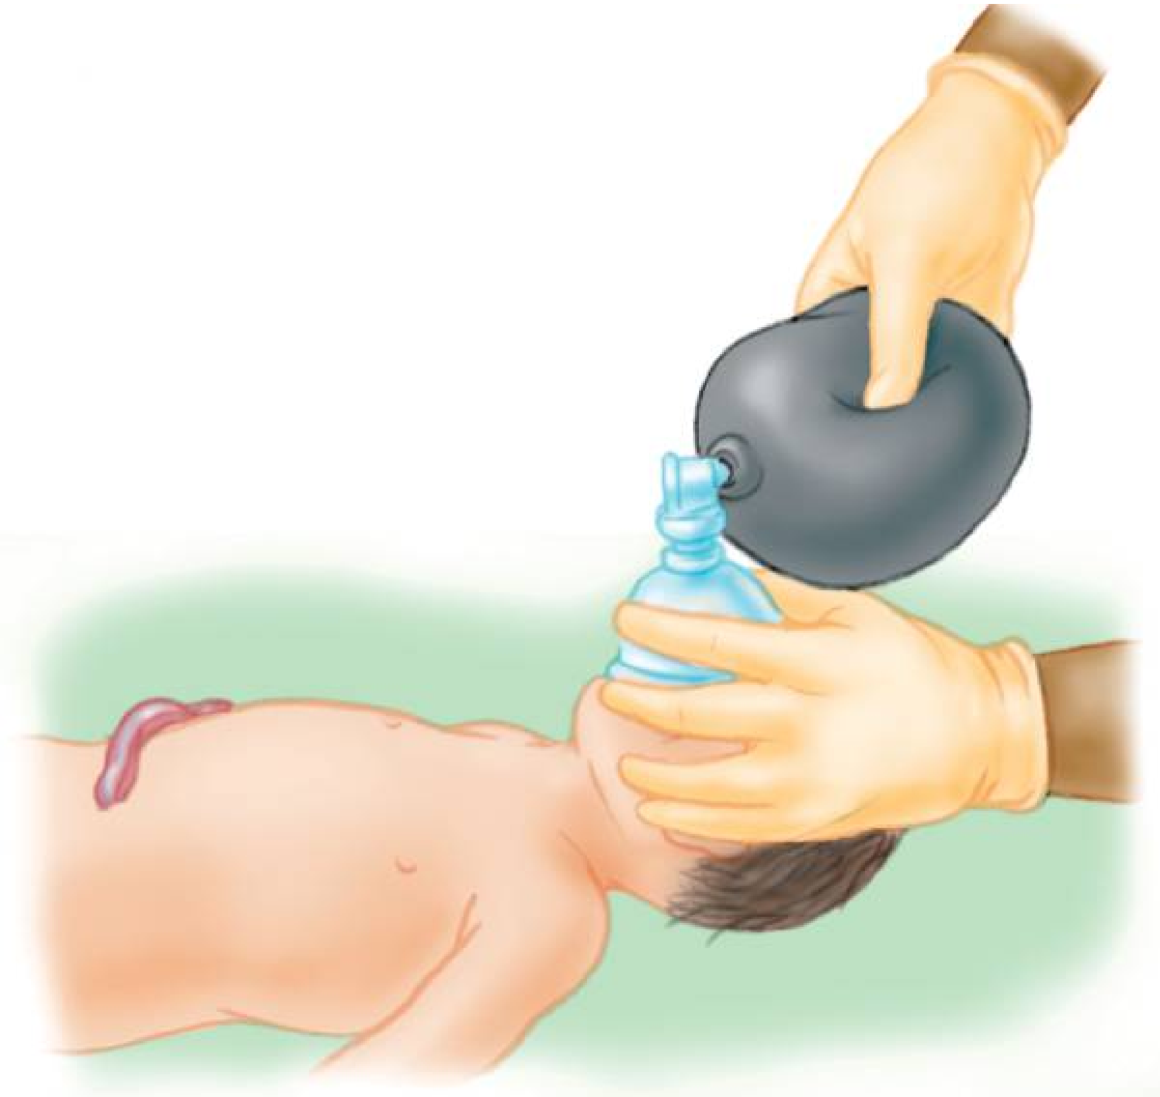
SKILL DRILL 23-3 Resuscitating a Neonate



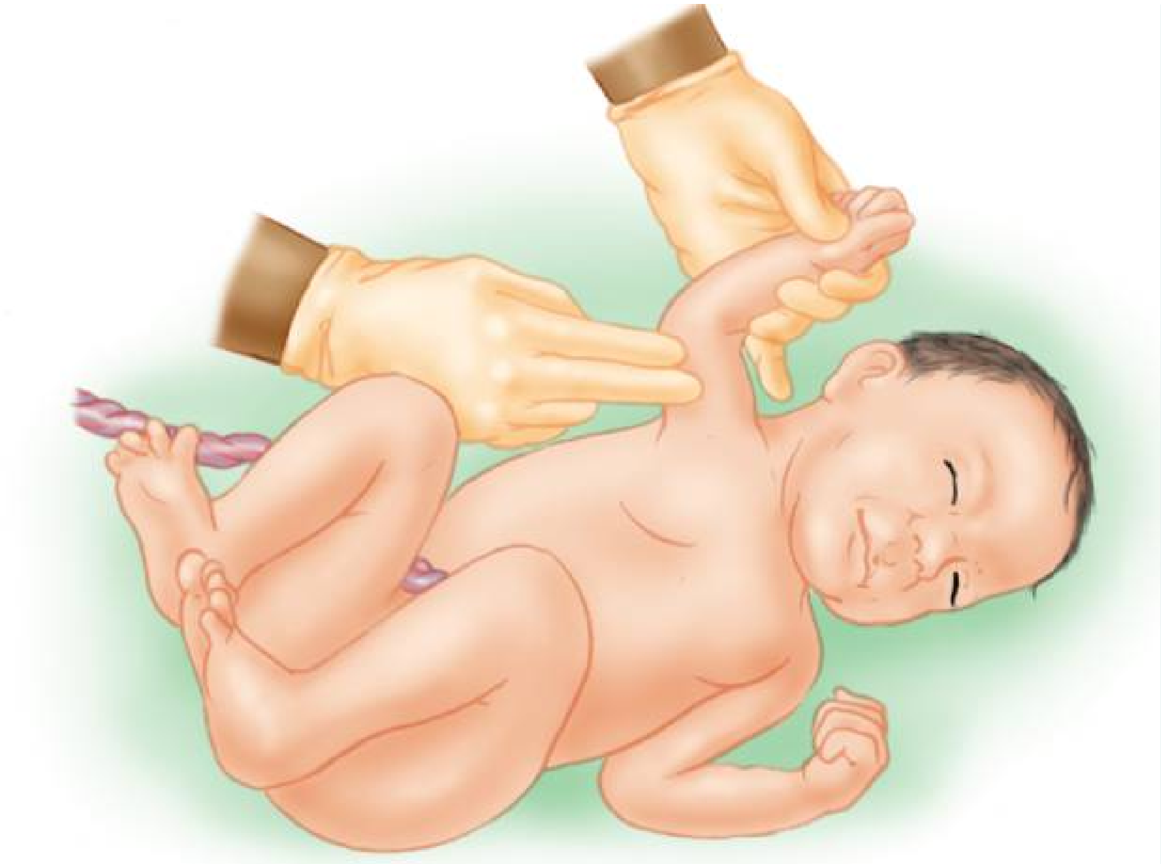
Step 1
Lay the neonate flat. Suction the mouth and nose with a bulb syringe.



Step 2
If drying and suctioning do not successfully induce breathing, gently flick your fingers against the soles of the neonate’s feet.

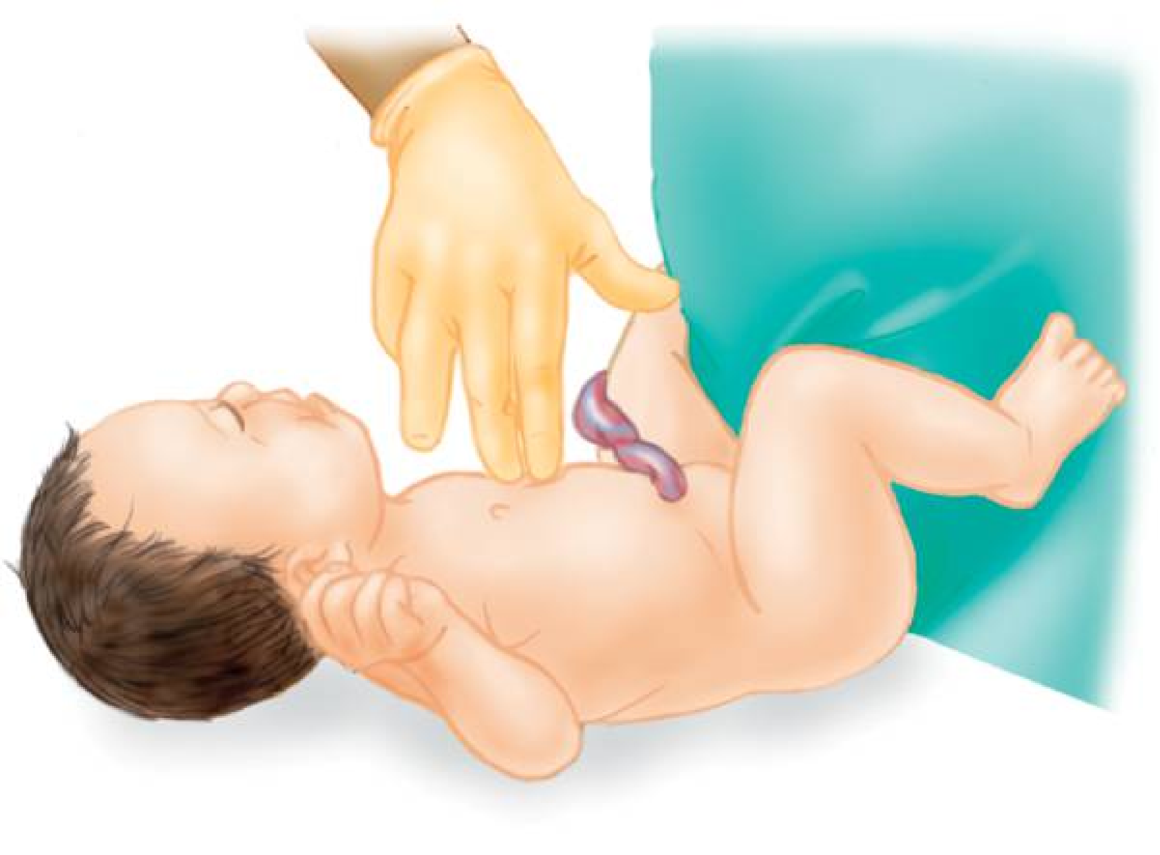


Step 3
Begin bag-mask ventilation if the neonate is not breathing effectively.



Description

Step 4
If the neonate is still not breathing, continue bag-mask ventilation and check for an umbilical, femoral, or brachial pulse. The brachial location is shown here.



Step 5
If you cannot feel a pulse or if the heart rate is less than 60 beats/min, begin chest compressions.

© Jones & Bartlett Learning.

1. Lay the neonate flat (Trendelenburg position can cause intracranial hemorrhage, especially in preterm infants) **STEP 1**. Ensure that the airway is open (head in sniffing position). Add a shoulder roll to obtain the optimal position.
2. Dry the infant to stimulate the infant to breathe. If this action does not suffice to initiate breathing, gently flick your fingers against the soles of the neonate’s feet and/or rub the neonate’s back. Routine suctioning immediately after the birth of the baby is not recommended; it should be used only if copious secretions are obstructing the airway **STEP 2**. Rough handling is not needed. Do not shake the baby.

3. PEEP may be used if the infant had inadequate chest rise but has initiated breathing. Observe closely to ensure the airway remains patent.
4. If the neonate is still not breathing effectively, begin PPV **STEP 3**. If the neonate begins breathing on their own, support and assist respirations and recheck the airway to confirm it remains clear.
5. If the neonate is still not breathing, continue the PPV and check for an umbilical, femoral, or brachial pulse **STEP 4**. It is important to intermittently auscultate the pulse using a stethoscope.
6. If you cannot feel a pulse or if the heart rate is less than 60 beats/min, begin closed-chest cardiac compressions **STEP 5**.

The depth of compression is one-third of the anterior-posterior diameter of the chest. The CCTP's fingers should remain in contact with the patient's chest at all times to minimize risk of trauma. Time the compressions in synchrony with artificial ventilation, which continues during chest compressions. (In neonates, even if respirations are being supported by PPV, the ventilation is still timed with the chest compressions.) The CCTP delivering the chest compression counts aloud, "One and two and three and breathe and. . . ." Downward strokes of chest compressions should be delivered each time a number (*one*, *two*, or *three*) is spoken. Release of the strokes should occur on the "and" that follows "three." The CCTP ventilating delivers a breath during "breathe and." This sequence results in 90 compressions and 30 breaths/min. Note that this rate applies to one-rescuer infant CPR; it is best to use two rescuers when a faster compression rate is needed. Heart rate is assessed at 30-second intervals, and chest compressions are stopped when the heart rate is greater than 60 beats/min. Liver laceration and rib fractures are possible risks of delivering chest compressions.

If the neonate is not responding to resuscitation, other causes must be considered. Generally, the difficulties relate to the following issues: technical/mechanical/equipment problems, unrecognized pulmonary complications, severe metabolic derangements, congenital abnormalities of organ systems, or severe anemia.

Pharmacologic Interventions

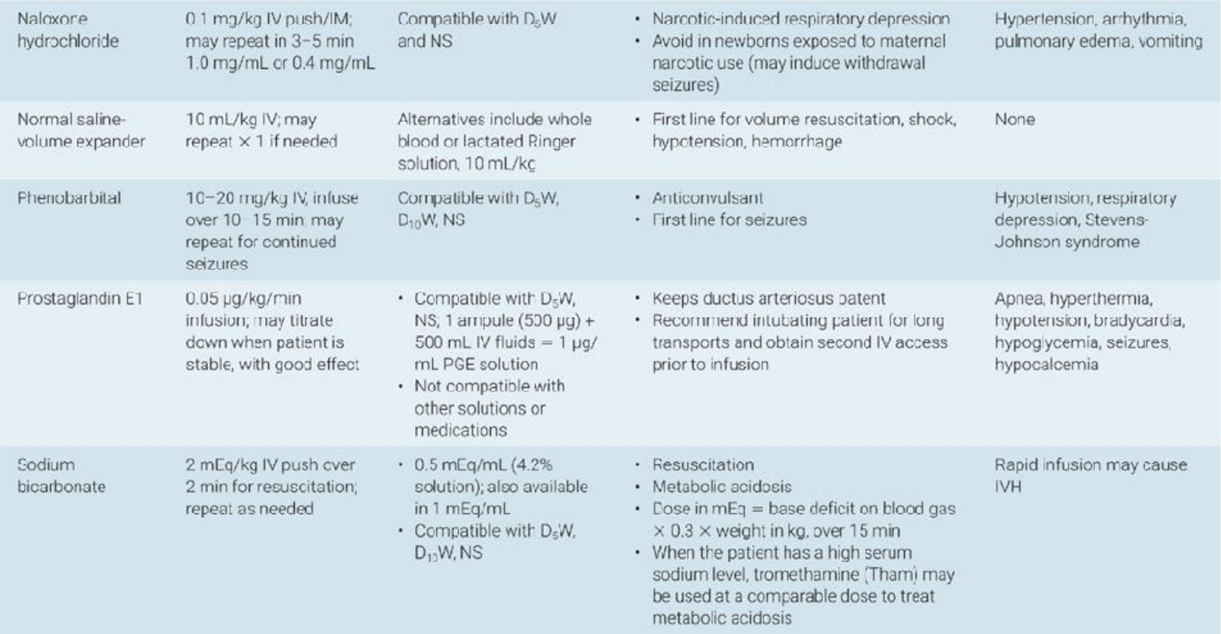
Medications are rarely needed in neonatal resuscitation because most infants can be resuscitated with effective ventilatory support. Epinephrine is indicated when the heart rate remains less than 60 beats/min despite intubation, effective ventilation with 100% oxygen, and chest compressions. Normal saline bolus or O-negative blood infusion may be indicated for infants with hypovolemia, blood loss, or suspected metabolic acidosis while awaiting blood gas results; lactated Ringer solution is no longer recommended for neonatal resuscitation. All fluids and medications can be infused through the umbilical venous line or into an intraosseous needle in both term and preterm newborns.

Sodium bicarbonate is no longer recommended in the initial resuscitation, though it may be used with caution when the degree of metabolic acidosis is known from a blood gas analysis. Similarly, naloxone and vasopressors are no longer recommended for the initial resuscitation, but may be useful after resuscitation.

Doses of medications in neonates are based on weight, so the CCTP may need to estimate the infant’s weight for dosing purposes. A term infant usually weighs approximately 6.5 to 8.5 pounds (3 to 4 kg). An infant born at 28 weeks’ gestation weighs an average of 2.2 pounds (1 kg), and an infant born at 34 weeks’ gestation weighs an average of 4.5 pounds (2 kg). Medications that may be used in this patient population are listed in **TABLE 23-10**.

TABLE 23-10 **Medications for Neonates**

Drug Name	**Dose/Route**	**Concentration**	**Indications/Comments**	**Side Effects**
Ampicillin	50 mg/kg IV over 5–10 min		• First-line antibiotic for sepsis workup • Use with gentamicin • Use 100 mg/kg if meningitis suspected	None
Atropine	0.01–0.03 mg/kg IV/IM; may repeat every 5 min × 3 orally: 2–3 × IV dose; minimum dose of 0.1 mg in infants >5 kg		• Preintubation medication to minimize vagal-induced bradycardia • Standard dose of 0.02 mg/kg used PALS	Tachycardia, arrhythmia, fever, rash, urinary retention
Cefotaxime	50 mg/kg IV every 6–12 h depending on weight/age		• Broad-spectrum antibiotic used for suspected/documented gram-negative sepsis	Potential increased risk of fungal infection due to broad spectrum of coverage
Ceftriaxone	50 mg/kg per dose IV/IM every 24 h		• Can be used to complete antibiotic course at home • Do not use in a newborn or a neonate with total bilirubin >5 mg/dL because it displaces bilirubin from albumin and can lead to kernicterus	Cases of fatal reactions with calcium-ceftriaxone precipitates in lungs and kidneys in both term and premature neonates have been described
Dextrose	2 mL/kg IV bolus over 5–10 min		• Symptomatic hypoglycemia (blood glucose level <40 mg/dL) • May use for hydration • May repeat bolus or follow with 5 mg/kg per min • Incompatible with blood products	None
Dobutamine	3–5 μg/kg per min IV; increase 3–10 μg/kg per min to max 40 μg/kg/min		• Cardiogenic shock, hypotension, increased myocardial contractility, cardiac failure • Try volume resuscitation first • Incompatible with sodium bicarbonate	Hypoxemia, tachycardia, arrhythmia
Dopamine	5 μg/kg per min IV, increase 2–3 μg/kg per min to max 40 μg/kg/min for effect		• Nonhypovolemic shock, increased cardiac output • Try volume resuscitation first	Hypoxemia, tachycardia, arrhythmia
Epinephrine	0.01–0.03 mg/kg or 0.1–0.3 mL/kg ET or IV every 3–5 min; may titrate IV dose up to max 1 μg/kg/min for effect		• Resuscitation medication for asystole and bradycardia • Bronchodilator • Standard dose used in PALS and recommended by AAP is 0.01 mg/kg IV	Arrhythmia, hypertension, IVH, renal failure, hypokalemia
Gentamicin	4 mg/kg IV/IM (IV preferred) over 30 min OR By gestational age: >35 weeks, 4 mg/kg 30–34 weeks, 4.5 mg/kg <29 weeks, 5 mg/kg	Reconstitute with sterile water • In D_5W, $D_{10}W$ NS: infuse over 30 min • In D_5W, $D_{10}W$ NS: IV infusion given over 30–60 min • In $D_{25}W$: dilute to <12.5% to give via peripheral IV 12.5 μg/mL; reconstitute in D_5W/$D_{10}W$/NS, 40 μg/mL; reconstitute in D_5W/$D_{10}W$/NS, 0.1 mg/mL; dilute 1:1 for ET administration • Compatible with TPN, NS, D_5W, $D_{10}W$	• Part of sepsis workup • Obtain cultures before administering • Do not give with cephalosporin	None
Inhaled nitric oxide	20 ppm starting dose		• Selective decrease in pulmonary vascular resistance • Used for PPHN levels • Started with oxygenation index >25 • Needs specific delivery device	Methemoglobinemia: need daily methemoglobin levels
Morphine sulfate	0.05–0.1 mg/kg IM/IV over 15–20 min (may push over 4–5 min if needed), then every 4 h or 10–15 μg/kg/h infusion	Compatible with D_5W, $D_{10}W$, NS	• Analgesia and sedation • Do not discontinue suddenly • Do not use in shock and increased intracranial pressure • Use naloxone as antidote for respiratory depression	Respiratory depression, hypotension, bradycardia



Naloxone hydrochloride	0.1 mg/kg IV push/IM; may repeat in 3–5 min 1.0 mg/mL or 0.4 mg/mL	Compatible with D_5W and NS	• Narcotic-induced respiratory depression • Avoid in newborns exposed to maternal narcotic use (may induce withdrawal seizures)	Hypertension, arrhythmia, pulmonary edema, vomiting
Normal saline-volume expander	10 mL/kg IV; may repeat × 1 if needed	Alternatives include whole blood or lactated Ringer solution, 10 mL/kg	• First line for volume resuscitation, shock, hypotension, hemorrhage	None
Phenobarbital	10–20 mg/kg IV, infuse over 10–15 min; may repeat for continued seizures	Compatible with D_5W, $D_{10}W$, NS	• Anticonvulsant • First line for seizures	Hypotension, respiratory depression, Stevens-Johnson syndrome
Prostaglandin E1	0.05 µg/kg/min infusion; may titrate down when patient is stable, with good effect	• Compatible with D_5W, NS; 1 ampule (500 µg) + 500 mL IV fluids = 1 µg/mL PGE solution • Not compatible with other solutions or medications	• Keeps ductus arteriosus patent • Recommend intubating patient for long transports and obtain second IV access prior to infusion	Apnea, hyperthermia, hypotension, bradycardia, hypoglycemia, seizures, hypocalcemia
Sodium bicarbonate	2 mEq/kg IV push over 2 min for resuscitation; repeat as needed	• 0.5 mEq/mL (4.2% solution); also available in 1 mEq/mL • Compatible with D_5W, $D_{10}W$, NS	• Resuscitation • Metabolic acidosis • Dose in mEq = base deficit on blood gas × 0.3 × weight in kg, over 15 min • When the patient has a high serum sodium level, tromethamine (Tham) may be used at a comparable dose to treat metabolic acidosis	Rapid infusion may cause IVH

Abbreviations: AAP, American Academy of Pediatrics; D_5W, 5% dextrose in water; $D_{10}W$, 10% dextrose in water; $D_{25}W$, 25% dextrose in water; ET, endotracheal; IM, intramuscularly; IVH, intraventricular hemorrhage; MI, myocardial infarction; NS, normal saline; PALS, pediatric advanced life support; PGE, prostaglandin E; PPHN, persistent pulmonary hypertension

© Jones & Bartlett Learning.

Description

Epinephrine

If the infant has a pulse rate of less than 60 beats/min after 30 seconds of effective ventilation after intubation and 60 seconds of chest compressions, administration of epinephrine is indicated. The recommended concentration for neonates is 1:10,000. The recommended dose is 0.1 to 0.3 mL/kg of 0.1 mg/mL epinephrine IV, equal to 0.01 to 0.03 mg/kg, administered rapidly, and followed by a 0.5- to 1-mL normal saline flush to clear the line. While IV is the optimal route to deliver epinephrine, if IV access is not yet established, consider starting with the higher dose of 0.3 to 1.0 mL/kg of 0.1 mg/mL epinephrine via the ET tube. It is important to recheck the infant's heart rate 1 minute after administering the dose (and for longer if this medication is given endotracheally). Epinephrine dosing may be repeated every 3 to 5 minutes for persistent bradycardia.

Volume Replacement

Fluid resuscitation may be needed if the infant's intravascular volume is significantly depleted from conditions such as abruptio placentae or septic shock. Signs of hypovolemia include pallor, delayed capillary refill, and weak pulses despite a good heart rate or high-quality chest compressions—defined as compressions delivered at a depth of approximately one-third of the anterior-posterior diameter of the chest that allow for full chest recoil, at a rate of 90 compressions per minute with minimal interruptions. In the neonate, the specific depth is important because the size of the child will vary. Compressing too little leads to ineffective compressions; compressing too deeply leads to trauma.

In a newborn, a low umbilical venous catheter can be placed in the large vein in the umbilical cord by advancing the catheter just far enough to allow blood return, but not far enough to enter the liver. In an infant older than a few days, a peripheral IV or intraosseous (IO) line will need to be placed. Note that while the technique for placing an IO line in a neonate is similar to that used in older children or adults, a smaller needle should be used to avoid exiting the far side of the bone.

A fluid bolus in an infant consists of 10 to 20 mL/kg of normal saline IV over 5 to 10 minutes. More than one bolus may be needed if the patient is still clinically hypovolemic.

Ventilation During Transport

Neonatal transport incubators are typically fitted with a ventilator that provides synchronized intermittent mandatory ventilation. Settings are adjusted relative to the patient's condition. Peak inspiratory pressure is adjusted to provide a comfortable breath (typically 14 to 20 mm Hg; the lower range is appropriate for more premature infants, while the higher range is appropriate for term infants with decreased lung compliance (like that seen in pneumonia). The peak end-expiratory pressure is typically 3 to 4 mm Hg, the rate is 20 to 60 breaths/min, and the inspiratory time is 0.3 to 0.4 second. If volume ventilation is used, a tidal volume of 6 to 8 mL/kg is targeted. The ventilator tubing can affect the measured tidal volume on some ventilator circuits, making close observation of chest rise and peak inspiratory pressure critical, especially when first placing a neonate on tidal volume ventilation.

For patients with very severe lung disease, a conventional ventilator may not provide adequate support. High-frequency ventilation, defined as a respiratory frequency of 400 to 800 breaths/min and optimal PEEP (usually higher than that used with conventional ventilation), relies primarily on convection and molecular diffusion of gas rather than tidal volume ventilation to exchange oxygen and carbon dioxide. Some transport incubators may be fitted with a high-frequency ventilator, in which case comparable ventilator settings can be used for transport. Frequently, however, only a conventional ventilator is available for transfer.

When switching a neonate from high-frequency ventilation back to a conventional ventilator, the neonate usually tolerates the fastest rate that the conventional ventilator can deliver; inspiratory pressures need to be kept relatively low and expiratory times long (I:E at least 1:2) to minimize the risk of air trapping. If the neonate is critically ill and the desired oxygen saturation cannot be maintained on a conventional transport ventilator, manually ventilating the child with a T-piece resuscitator or bag-mask device may provide acceptable ventilation and oxygenation until arrival at a tertiary care center.

For term infants with respiratory failure, some centers can initiate inhaled nitric oxide to optimize pulmonary vasodilation or extracorporeal membrane oxygenation to support cardiopulmonary function in the field, and then transport the neonate on inhaled nitric oxide or an extracorporeal membrane oxygenation circuit. It is important to have discussions with the regional referral center in advance to know which technology is available in the area.

Additional Transport Considerations

While PPV and chest compressions can be performed in a moving emergency vehicle, a key consideration is to secure the neonate’s airway before beginning the transport. The neonate is best stabilized at the originating center.

Evaluation during air transport is especially difficult because of the vibrations, noise, and poor lighting inherent to aircraft. In this setting, CCTPs must rely on cardiorespiratory equipment to determine the stability of vital signs. Procedures such as intubation or needle aspiration of the chest can be particularly challenging in flight because of the limited space available and the inability to maintain a stable environment for needle aspiration. For all these reasons, the neonate’s airway must be secured prior to a helicopter flight.

If additional interventions such as intubation or needle aspiration are needed during ambulance transport, it is recommended that the CCTP consider pulling the ambulance to the side of the road while performing the procedure. During a flight transport, the CCTP needs to rely more on nonauditory assessments (visual, tactile, electronic monitoring) to provide care and perform necessary procedures. If necessary, PPV can be performed during air transport if the ET tube becomes dislodged and cannot be readily replaced.

Respiratory Conditions

Clearing the airway and providing stimulation are sufficient to establish adequate cardiorespiratory function in most neonates. However, a small subset of these patients need assisted ventilation, as discussed earlier. Conditions that can induce respiratory compromise in the neonate include anatomic anomalies leading to obstruction, such as choanal atresia and Pierre Robin syndrome. Both of these conditions respond to placement of an oral airway. The next sections discuss specific respiratory conditions, their causes, and their management.

Apnea

Apnea is defined as a pause in respirations of more than 20 seconds. It is often associated with cyanosis, pallor, **hypotonia** (low or poor muscle tone), or bradycardia.

There are two types of apnea: primary and secondary apnea. **Primary apnea** is present at birth; it is the initial response to asphyxia at birth. This condition responds well to stimulation and oxygen supply. If asphyxia continues beyond the primary apnea period, **secondary apnea** sets in after a few deep gasping breaths. This condition responds only to assisted ventilation and supplemental oxygen. Although these two types of apnea might seem clinically indistinguishable, it is critically important to recognize the difference between them so as to provide appropriate management.

In the neonate, apnea may have many etiologies. Respiratory causes include fixed anatomic obstruction, positional obstruction (head on chin, obstructing the airway), secretions, and reflux with aspiration. Metabolic causes include hypoglycemia, inborn errors of metabolism that cause high ammonia levels, and hypocalcemia. Cardiovascular causes include poor tissue oxygenation from arrhythmia, CHD, shock, anemia/hemorrhage, patent ductus arteriosus, and hypotension. Infectious etiologies include necrotizing enterocolitis, pneumonia, sepsis, respiratory syncytial virus, *Chlamydia*, and pertussis. Neurologic causes include seizures, encephalopathy, intraventricular hemorrhage, congenital hypoventilation, increased intracranial pressure, stroke, and apnea of prematurity. Hypothermia or hyperthermia, trauma, child abuse, and exposure to illicit drugs or prescribed medications need to be considered as well.

Apnea is treated in the field by following a multiple-step approach:

- Stabilization: Assess and manage the ABCs as needed. Apnea is often associated with cyanosis and bradycardia. Administer free-flow oxygen at 2 L/min for cyanosis. If this measure does not improve the neonate's color and respirations, assisted ventilation may be needed. If apnea and bradycardia persist, intubate the neonate prior to transport.
- Assessment: Perform a brief history, physical exam, and lab tests.
    - Check the fontanelle for a bulge, which may indicate increased intracranial pressure.
    - Check the nose and oropharynx for obstruction.
    - During the cardiac exam, listen for murmurs; during pulmonary auscultation, listen for crackles.
    - Check capillary refill to assess perfusion.
    - Obtain a set of vital signs, including temperature.
    - Check the blood glucose level.
    - Ensure that a complete blood count (CBC), blood cultures, chest radiograph, a blood gas analysis, and electrolyte levels are obtained, if possible.
- Further management: Keep the neonate warm except if hypoxic ischemic encephalopathy (as defined by strict criteria) is suspected. Administer 2 mL/kg of 10% dextrose as a bolus if the glucose level is less than 40 mg/dL. It may be necessary to start IV fluids for hypoglycemia. Administer antibiotics (eg, ampicillin, gentamicin) if these agents have not been started. (The sepsis

workup is often started at the sending facility and antibiotics are chosen by the sending physician.) Naloxone may be indicated after the initial resuscitation and stabilization if the neonate is positive for an acute (not chronic) exposure to narcotics.

Causes of Respiratory Distress in a Neonate

Meconium-Stained Amniotic Fluid

Meconium, the first stool of an infant, is usually expelled after birth. However, it may be expelled in utero in term infants during fetal stress. Postterm infants are at even higher risk for meconium-stained amniotic fluid due to their relatively impaired placental functions. Meconium-stained amniotic fluid is present in 10% to 15% of deliveries.

Meconium aspiration occurs when infants inhale the meconium into their lungs when hypoxia or acidosis causes the infant to take a gasping breath before or during the delivery. If the infant inhales the meconium-stained amniotic fluid either in utero or at delivery, plugging of the airways and hypoxia can follow. The respiratory distress caused by meconium aspiration is termed **meconium aspiration syndrome**. It can lead to atelectasis in the lungs, persistent pulmonary hypertension (delayed transition from fetal to neonatal circulation), pneumonitis, and pneumothorax. The differential diagnosis for meconium aspiration syndrome includes respiratory distress syndrome, **transient tachypnea of the newborn** (transient respiratory distress that lasts a few hours and occurs secondary to retained fetal lung fluid), sepsis, pneumonia, and congenital respiratory or cardiac malformation. In infants who have aspirated meconium, patchy/fluffy infiltrates may be seen on the chest radiograph **FIGURE 23-9**.

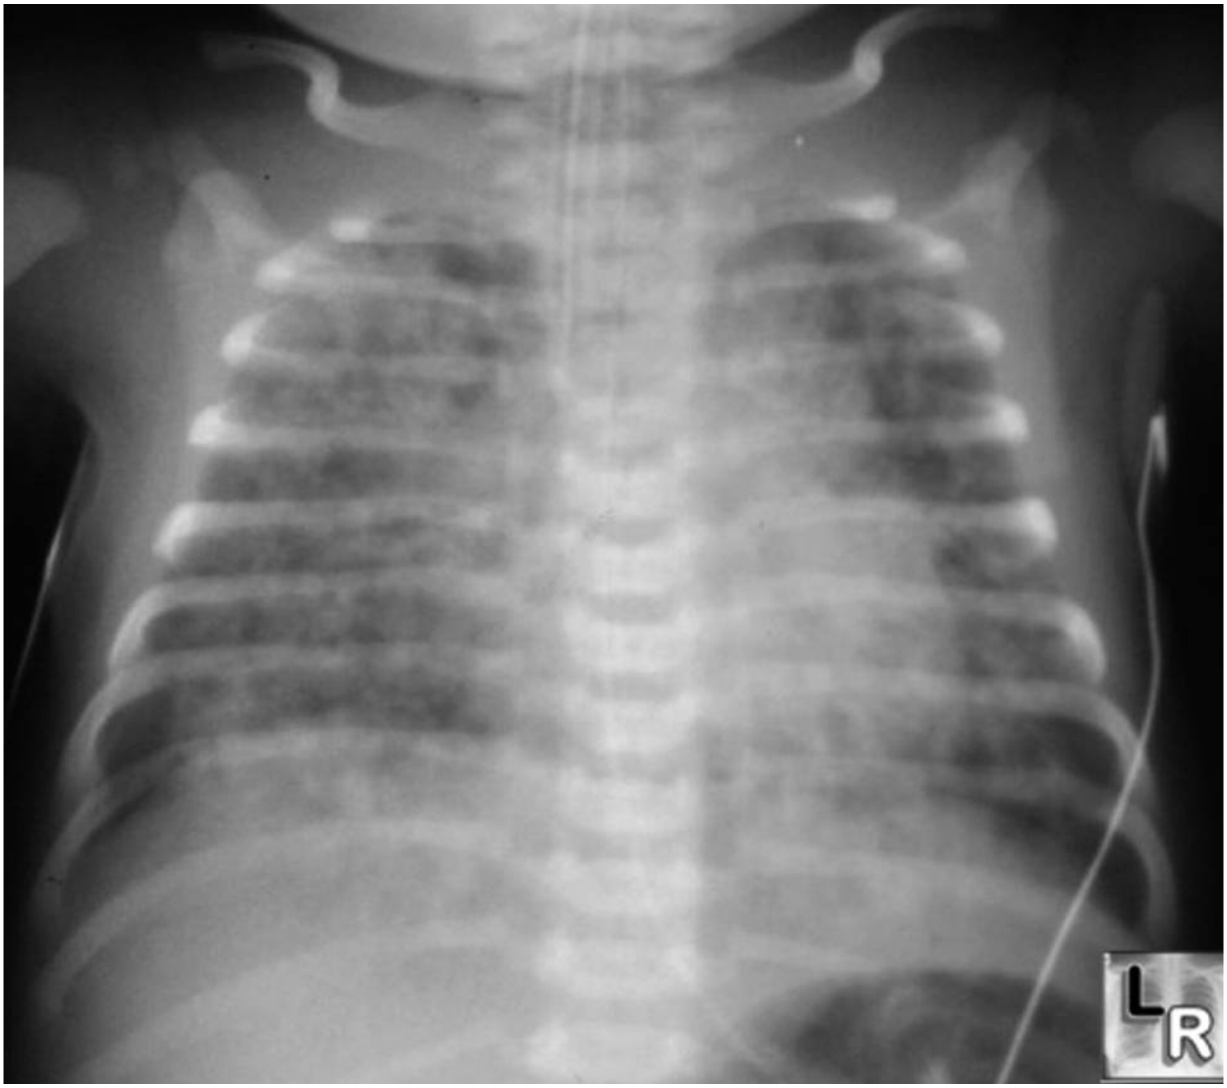


FIGURE 23-9 A chest radiograph with patchy/fluffy infiltrates, indicating meconium aspiration syndrome.

Published with permission of LearningRadiology.com.

If meconium is present in the amniotic fluid of a depressed newborn at birth, tracheal intubation and aspiration are no longer recommended because this intervention's efficacy is supported by only minimal evidence. Even when tracheal suctioning is performed, meconium aspiration syndrome may occur. When transporting an infant exposed to meconium-stained amniotic fluid who shows respiratory symptoms after delivery, it is important to monitor for the development of complications from meconium aspiration syndrome, such as worsening lung compliance and pneumothorax, and to intervene as necessary. Consider implementing PPV during transport if progressive hypoxia develops. A pattern of short inspiratory time and long expiratory time is commonly used to provide adequate ventilation and minimize air trapping in the neonate. High PEEP values may also be used.

A needle setup should be available in the event that the infant develops a significant pneumothorax en route to the hospital. If a significant pneumothorax develops, as suggested by acute cyanosis, increased work of breathing, and decreased breath sounds, clean the area just above the patient's nipple on the affected side. Then insert a small (22-gauge) butterfly needle in the second intercostal space, at the midclavicular line, above the rib, while pulling back on a syringe to evacuate the extrapleural air and relieve the intrathoracic pressure. This procedure is discussed further in the section on pneumothorax and illustrated in **FIGURE 23-10**.

Description

Pneumonia

Neonates have an impaired immune response and as a result are at increased risk of developing pneumonia. Signs and symptoms of pneumonia include tachypnea (respiratory rate greater than 60 breaths/min), increased work of breathing, and hypothermia. The initial assessment for suspected pneumonia should include a chest radiograph, blood gas measurements in infants with significant respiratory symptoms, CBC, and blood culture. Management includes antibiotics (eg, ampicillin and gentamicin), maintaining the infant on nothing given by mouth (abbreviated NPO for the Latin *nil per os*) status until the respiratory symptoms resolve (because of the increased risk of aspiration), and administering IV fluids to maintain hydration and blood glucose levels. Respiratory support such as supplemental oxygen and PPV should be provided based on the infant's clinical condition and oxygen saturation level.

Signs and Symptoms

Pneumonia

- Tachypnea
- Increased work of breathing
- Hypothermia

Transport Management

Pneumonia

- Maintain the infant on NPO status.
- Provide IV fluids.
- Provide respiratory support.

Respiratory Distress Syndrome

Infants delivered prematurely, especially at less than 32 weeks' gestation, have a high risk of experiencing respiratory distress syndrome (RDS) as the result of insufficient levels of surfactant, a surface-active agent that occurs naturally in the lungs and minimizes surface tension in the lungs. Within a few hours of birth, neonates with RDS present with grunting, retractions, nasal flaring, tachypnea, and, often, cyanosis. Male infants and infants of mothers with diabetes are at increased risk of RDS. Surfactant inactivation can also occur due to interactions with abnormal alveolar proteins such as meconium or blood or, in the case of pneumonia, albumin. Both surfactant deficiency and dysfunction may respond to exogenous surfactant, when it is administered in a controlled clinical setting by providers experienced in its delivery.

When transporting an infant after surfactant administration, the CCTP needs to recognize when lung compliance is improving and when respiratory support might need to decrease (eg, wean the patient oxygen as oxygen saturation improves, decrease peak pressure as chest excursion improves). Peak pressures and oxygen concentration should be minimized as appropriate throughout transport to minimize the risk of pneumothorax and chronic lung disease. An oxygen saturation range of 88% to 92% should be targeted during transport of premature infants with RDS to minimize oxygen toxicity. CPAP can be helpful in neonates with mild RDS to minimize the risk of alveolar collapse during transport.

Standard nasal cannula therapy uses a maximum flow of 2 L/min to avoid drying out the mucous membranes in the nares. Special equipment that supplies humidified gas can be used to provide high-flow nasal cannula therapy, typically at gas flows between 2 and 6 L/min. Some institutions utilize high-flow therapy instead of CPAP. This therapy should be avoided during transport, however, because the high flow can provide excessive PEEP and increase the risk of pneumothorax.

In patients with suspected RDS, ensure that a sepsis workup has been performed prior to transport because pneumonia in the newborn is indistinguishable from RDS. Prevent cold stress by keeping the neonate warm and bundled.

Pneumothorax

Simple **pneumothorax** is a collection of gas in the pleural space that causes lung collapse. Tension pneumothorax is a life-threatening condition that involves air in the pleural space under pressure. Causes of pneumothorax include meconium aspiration, pneumonia, neonatal resuscitation, trauma, and aggressive assisted ventilation.

A pneumothorax may be treated by inserting an angiocatheter in the second intercostal space, at the midclavicular line, above the rib. The introducer needle is then removed to prevent a tension pneumothorax from developing, and the angiocatheter is attached to the extension tubing. Note that the angiocatheter may further tear the lung during its initial placement and is more likely to kink than is a butterfly needle. Remove as much air as possible with the syringe. At this point, the CCTP may briefly occlude the tubing while placing the end of the tubing that had been attached to the syringe in a small bottle of sterile water and release the tubing occlusion. This relieves the pressure buildup from the tension pneumothorax until the patient can be transferred to a facility skilled in placement of chest tubes in neonates. Intubate the infant if the respiratory distress continues.

Consider pneumothorax if the patient exhibits cyanosis, increased oxygen requirements, tachypnea, increased work of breathing, agitation, or tachycardia. If the pneumothorax is large or under pressure, life-threatening hypoxia, bradycardia, and hypotension may occur. Management of pneumothorax includes transillumination, thoracentesis (if significant cardiorespiratory compromise exists), and possibly intubation, while recognizing that PPV may cause an enlargement of the pneumothorax.

When transillumination is performed, increased transmission of light on one side of the chest suggests pneumothorax. A chest radiograph will confirm the diagnosis. Findings include an ipsilateral edge of the lung parallel to the chest wall, lucency, and a deep **sulcus sign** (deep lateral costophrenic angle). Mediastinal shift to the contralateral side is seen in patients with tension pneumothorax.

If a symptomatic pneumothorax is suspected, a needle thoracentesis can be lifesaving. On the side of the suspected pneumothorax, clean the area around the second intercostal space, at the midclavicular line (usually just above the nipple) with alcohol (Figure 23-10). Prepare the equipment needed: a 22-gauge butterfly needle attached to extension tubing, a three-way stopcock, and a 20-mL syringe. Insert the needle above the third rib (in the second intercostal space) as a second provider pulls back on the syringe (which is open to the patient). The nerves and blood vessels run below the ribs, so avoid piercing this area **FIGURE 23-11**. Continue to slowly advance the needle until air is recovered. The butterfly needle is rigid, so be gentle so as to avoid further tearing of the lung. If the 20-mL syringe becomes filled with air, turn the stopcock off to the neonate, push out the air from the syringe, open the stopcock to the neonate, and continue withdrawing air. When no more air can be withdrawn, remove the needle. If the patient has a symptomatic ongoing air leak, a 22-gauge angiocatheter attached to extension tubing can be left in place, with the distal end of the tubing placed under sterile water to create a water seal.

Description

Respiratory Acidosis

Respiratory acidosis may be caused by maternal drug use that results in respiratory depression in the neonate, or by a primary pulmonary or neurologic cause of suboptimal gas exchange. This imbalance frequently presents with visually apparent hypoventilation or increased work of breathing, and often responds to assisted ventilation.

Management of Respiratory Distress and Failure

Respiratory problems are a major cause of cardiac arrest in newborns and infants. Prompt recognition and effective management of respiratory distress and failure are fundamental to pediatric life support because clinical deterioration in respiratory function may progress rapidly. The primary goal is to restore adequate oxygenation and ventilation. **TABLE 23-11** lists measures for ensuring the airway, breathing, and circulation of a neonate with respiratory distress or failure.

TABLE 23-11 Management of Respiratory Distress and Failure

Assessment Parameter	Action as Indicated
Airway	• Support the airway. • Clear the airway (suction the nose and mouth as needed). • Insert an oropharyngeal airway if indicated.
Breathing	• Assist ventilation (bag-mask ventilation or intubation). • Provide oxygen (humidified, if available). Begin with 100% oxygen and wean appropriately based on oximetry. • Continuously monitor oxygen saturation by pulse oximetry. • Prepare for intubation as indicated.
Circulation	• Monitor heart rate and rhythm. • Establish vascular access for fluid resuscitation and medications.

© Jones & Bartlett Learning.

Assessment of circulation includes both cardiovascular function and end-organ function. Cardiovascular function is assessed by skin color, temperature, heart rate, rhythm, BP, peripheral and central pulses, and capillary refill time. End-organ function is assessed by evaluation of mental status (brain perfusion), skin perfusion, and renal output. A systolic BP of less than 60 mm Hg in a term infant up to 1 month of age and of less than 70 mm Hg in a neonate up to 6 months of age is an ominous sign. Hypotension represents a state of shock in which physiologic compensatory mechanisms (tachycardia, vasoconstriction) have failed. Hypotension with hemorrhage is consistent with a 20% to 25% loss in circulating volume, whereas hypotension in septic shock represents inappropriate vasodilation rather than loss of circulating volume. Aggressive fluid resuscitation, along with management of the airway and breathing, are needed to prevent cardiac arrest.

Cardiovascular Conditions

Cyanosis

Cyanosis (blue coloration of the gums and face) is caused by decreased arterial oxygenation. Acrocyanosis, or cyanosis of the extremities, with baseline skin color centrally is a benign, common condition that presents as blue coloration of the hands and feet and is often seen in newborns secondary to cold stress and peripheral vasoconstriction.

Cyanosis often presents in association with poor perfusion and congestive heart failure. It may also present with shock or result from either a pulmonary or cardiac process. Cardiac causes of cyanosis include cyanotic CHD, arrhythmia, cardiomyopathy, patent ductus arteriosus, and myocarditis. Noncardiac causes of cyanosis include persistent pulmonary hypertension (PPHN), sepsis/pneumonia, RDS, aspiration pneumonitis (meconium/blood), severe anemia, and arteriovenous malformation.

Cyanotic Congenital Heart Disease

Cyanotic congenital heart disease (CCHD) is caused by developmental anomalies of the heart or major vessels leading to abnormal blood flow. Deoxygenated blood from the right side of the heart is shunted to the left side, causing cyanosis. The cyanotic heart lesions are known as “the five Ts”: truncus arteriosus, transposition of the great vessels, tetralogy of Fallot, tricuspid atresia, and total anomalous pulmonary venous return. A hypoplastic left heart also leads to cyanosis.

Management of cyanosis in a neonate suspected of having CHD includes assessing the ABCs, monitoring BP and oxygen saturation (preferably upper and lower saturations to monitor for PPHN), optimizing oxygenation to prevent acidosis, and supporting cardiovascular function. Administer oxygen to the infant, using a nonrebreathing mask if needed, to keep the oxygen saturation level at greater than 70%. Hyperoxygenation can be harmful because it reduces pulmonary vascular resistance and diverts blood from the systemic circulation to the pulmonary circulation. For the same reason, hyperventilation can be harmful to the infant. Consider intubation if the patient has severe respiratory distress.

Obtain IV access as soon as possible. Obtain a CBC with a platelet count and a differential count, and perform electrolyte and blood gas analyses. Measuring arterial blood gases helps determine the degree of oxygenation/perfusion and ventilation. Ensuring that laboratory tests for lactate and hemoglobin are performed along with blood gas measurements is a quick way of determining the extent of acidosis and anemia. Simultaneous determinations of blood gases from the preductal (right arm) and postductal (left arm) extremities are also useful. A preductal-postductal difference in PaO_2 (partial pressure of arterial oxygen) of greater than 15 mm Hg indicates that the patient has PPHN.

Sodium bicarbonate may be needed if poor perfusion has caused significant metabolic acidosis (check for base excess on the blood gas analysis). Obtain four limb BP readings to help determine the level of stenosis/obstruction to blood flow. If possible, perform a hyperoxia test: It helps distinguish cardiac from noncardiac (lung disease) causes of cyanosis. This test is carried out by placing the infant in an **oxygen hood** with 100% oxygen for 20 minutes, then obtaining a blood gas measurement. A PaO_2 measurement greater than 150 mm Hg on the blood gas analysis essentially rules out cardiac causes of cyanosis, because deoxygenated blood bypasses the lungs and is shunted to the left side of the heart in the case of CHD. The exception to this rule is the condition known as **total anomalous pulmonary venous return**, in which oxygenated blood returns to the right side of the heart, leading to progressive pulmonary edema.

If results from a blood gas analysis are not readily available, upper and lower oxygen saturations can be obtained in their stead. A preductal saturation that is more than 10 points higher than the postductal saturation suggests pulmonary hypertension. Hyperoxia with hyperventilation supports PPHN as the cause of cyanosis. Correct any other metabolic abnormalities identified on the lab analysis.

Discuss the appropriateness of prostaglandin administration with the supervising physician. In the case of ductal-dependent congenital heart lesions (eg, transposition of the great arteries, left ventricular outflow obstruction), timely infusion of prostaglandin E1 is crucial to ensure a good outcome. This therapy keeps the ductus arteriosus open. In contrast, prostaglandin is not indicated in non–ductal-dependent lesions, but the actual diagnosis may not become clear until an echocardiogram is obtained.

An echocardiogram is used to assess the type of CHD and determine the presence of pulmonary hypertension; however, this type of study is often not available when transferring a neonate from a community hospital to a higher-level facility. If the diagnosis of CHD is suspected but uncertain during transport and the patient is severely acidotic, hypoxic, hypotensive, or poorly perfused, discuss a trial of prostaglandin with the supervising physician. The infant may need to be intubated for the infusion, as prostaglandin can cause apneas. Other side effects of this medication may include seizures, bradycardia, hyperthermia, and hypotension. Follow the patient's vital signs closely throughout the transport whenever prostaglandin is administered.

Some infants may have congestive heart failure and low BP/delayed capillary refill in addition to cyanosis. Management of hypotension includes a normal saline bolus as first-line therapy. After ensuring adequate volume expansion, consider administering inotropes or pressors. Agents for supporting BP include dobutamine and dopamine; the dose of each is 5 to 20 μg/kg/min. Administer sodium bicarbonate to treat severe acidosis.

Tachyarrhythmias and Bradyarrhythmias

Sinus tachycardia is defined as a heart rate faster than normal for the child's age. Heart rate generally varies with activity and other factors influencing oxygen demand (ie, the infant's temperature). Common pathologic causes of tachycardia include tissue hypoxia, hypovolemia, fever, metabolic stress, pain, anxiety, drugs, and anemia.

Supraventricular tachycardia (SVT) is an abnormally fast rhythm originating above the ventricles. It is the most common cause of tachyarrhythmia producing cardiovascular compromise in infancy. SVT is often caused by a reentry mechanism that involves an accessory pathway, atrioventricular nodal reentry, or ectopic atrial focus. **Wolff-Parkinson-White syndrome**, in which ventricular preexcitation produces a delta wave on electrocardiogram, is an example of a condition that produces SVT via an accessory pathway.

Infants often tolerate SVT quite well. They may present with symptoms of congestive cardiac failure, poor feeding, rapid breathing, irritability, pale or blue color, and vomiting. Initial management of SVT includes measuring the pulse and assessing for signs of adequate perfusion, supporting the ABCs and oxygenation as needed, obtaining an electrocardiogram to determine the rhythm, obtaining vascular access, and establishing monitoring by applying a cardiopulmonary monitor and/or pulse oximeter. Specific emergency interventions are dictated by the infant's condition and vary depending on the width of the QRS complex observed on the electrocardiogram. Vagal maneuvers, cardioversion, and pharmacologic interventions are among the options available to treat SVT, but should be performed under the supervision of a credentialed provider of such care. Children with tachyarrhythmias need to be evaluated by a pediatric cardiologist, though this assessment should not delay appropriate emergency treatment.

Bradycardia in a neonate is usually a result of tissue hypoxia and resolves when tissue oxygenation is restored. The most common neonatal bradyarrhythmia is due to maternal lupus, and results in heart block. If the resting fetal heart rate is low enough, hydrops (edema) develops. Postdelivery cardiac pacing may need to be initiated, but is usually nonurgent.

Signs and Symptoms

Supraventricular Tachycardia

- Symptoms of congestive heart failure
- Poor feeding
- Rapid breathing
- Irritability
- Pale or blue color
- Vomiting

Differential Diagnosis

Supraventricular Tachycardia

- Wolff-Parkinson-White syndrome
- Sinus tachycardia

Transport Management

Supraventricular Tachycardia

- Support the ABCs and provide oxygenation as needed.
- Monitor with a cardiopulmonary monitor and/or pulse oximeter.
- Perform vagal maneuvers, cardioversion, and pharmacologic interventions based on protocol.

Cardiac Arrest

In contrast to cardiac arrest in adults, sudden cardiac arrest in children is uncommon. Cardiac arrest in pediatric patients is more often caused by progression of respiratory distress, respiratory failure, or shock, typically associated with hypoxemia and acidosis, than by cardiac arrhythmias. In the United States, the incidence of sudden infant death syndrome has decreased significantly since the

Back to Sleep campaign (now called Safe to Sleep) began in the 1990s. This initiative instructs parents to place infants on their back to sleep. Trauma is an important cause of cardiopulmonary collapse in infants older than 6 months. Details of infant resuscitation, including the importance of adequate ventilation, have already been discussed.

Persistent Pulmonary Hypertension

Persistent pulmonary hypertension (PPHN) is persistence of elevated pressures in the pulmonary vasculature after birth. It is associated with failure to transition from the fetal circulation to the postpartum or normal newborn circulation. The elevated pulmonary BP causes ineffective pulmonary perfusion, hypoxemia, and right-to-left shunting of blood via the patent foramen ovale and/or patent ductus arteriosus. PPHN presents most often in term or postterm neonates, becoming evident within the first few hours of life. It frequently co-occurs with a combination of cyanosis, tachypnea, hypoxemia (often labile/fluctuating, respiratory distress, and differential oxygen saturations [upper > lower]).

The exact cause of PPHN is not understood, but several factors are known to contribute to the failure of normal circulatory transition at birth. For example, pulmonary vasoconstriction often occurs secondary to perinatal events. The most potent vasoconstrictors of the pulmonary artery are hypoxia and acidosis. Meconium aspiration is the most common cause of PPHN, often resulting in perinatal distress. Other conditions and risk factors associated with PPHN include RDS, asphyxia, pneumonia, hypothermia, hypoglycemia, and sepsis.

Abnormal development of the pulmonary vasculature is more frequently seen if the mother has taken nonsteroidal anti-inflammatory drugs during pregnancy and in infants of mothers with diabetes. It is also common in infants with chronic fetal distress/hypoxia resulting in hypertrophy of the vascular muscles of the pulmonary artery (characterized by idiopathic or black lung PPHN; no parenchymal disease is seen on a chest radiograph), aspiration, hypoxic ischemic encephalopathy, and congenital diaphragmatic hernia.

Special Populations

Infants of mothers with diabetes are at increased risk for shoulder dystocia and difficult delivery related to macrosomia, structural CHD, sacral agenesis, respiratory distress, and hypoglycemia.

For the CCTP caring for a neonate, it is important to have a low threshold of suspicion for PPHN. Care should be taken to optimize oxygenation, minimize stress, maintain a normal BP, and avoid or correct acidosis. Obtain a CBC, differential count, platelet count, and blood gas analysis for hyperoxia, and follow the patient's upper and lower oxygen saturations while treating the underlying cause of the PPHN.

Signs and Symptoms

Persistent Pulmonary Hypertension

- Cyanosis
- Tachypnea
- Hypoxemia (often labile/fluctuating)
- Respiratory distress
- Differential oxygen saturations

Shock

Shock is a serious condition in which perfusion is inadequate to meet the tissue demands; it can affect all organ systems in the body. To ensure sufficient oxygen delivery to the tissues, both lung ventilation and tissue perfusion are needed. Hypovolemia is a common cause of shock in neonates, often stemming from acute blood loss or fluid losses owing to decreased intake, polyuric renal failure, or diarrhea. Cardiogenic shock can follow CHD, arrhythmias, myocardial ischemia from asphyxia, cardiac tamponade, pneumothorax, or high intrathoracic pressure from PPV combined with secondary decreased venous return. Causes of distributive shock include sepsis, cardiac depression, and vasodilation.

Mean BP is often used to assess the adequacy of perfusion in a neonate, especially in the preterm population, where the lowest acceptable mean BP is equal to the gestational age of the neonate (eg, a mean arterial pressure of 28 mm Hg in a neonate at 28 weeks' gestation and a mean arterial pressure of 38 mm Hg in a neonate at 38 weeks' gestation).

Shock presents with some, if not all, of the following signs and symptoms: hypotension, tachycardia (or bradycardia, in cases of asphyxia), poor perfusion, tachypnea, oliguria/anuria, hypothermia, acidemia, and weak pulses. Hepatomegaly, cardiomegaly, and peripheral edema are seen in cardiogenic shock. Notably, the absence of a heart murmur does not rule out cardiogenic shock. Disseminated intravascular coagulopathy may be a late presentation.

Management of shock includes managing the ABCs, checking blood glucose levels, obtaining vascular access, providing fluid resuscitation, and treating the underlying cause. If it is necessary to provide fluids to support the patient's circulation or to deliver resuscitation medications intravenously to a neonate, emergent access must be obtained. Unfortunately, it is usually difficult to establish peripheral access in an infant who needs volume or resuscitation medications. In such a case, the umbilical vein in a newborn can be catheterized by using an umbilical vein catheter and following these steps:

1. Clean the umbilical cord with alcohol or another antiseptic.
2. Place a sterile tie firmly but not too tightly around the base of the cord for control of bleeding. If available, place a sterile drape over the site. While the line needs to be placed quickly in a code situation, maintain sterile technique as much as possible.
3. Prefill a sterile 3.5F to 5F umbilical vein line catheter (a comparable-size sterile feeding tube can be used in an emergency) with normal saline using a 3-mL syringe.

4. Using a sterile technique, wrap a tie around the base of the cord to control bleeding, and then cut the cord with a scalpel below the clamp placed on the cord at birth, about 0.5 to 0.75 inch (1 to 2 cm) from the skin (between the clamp and the cord tie).
5. The umbilical vein is a large thin-walled vessel usually at the 12 o'clock position, as compared to the two thick-walled umbilical arteries usually found at 4 and 8 o'clock **FIGURE 23-12**. Insert the catheter 0.75 to 1.5 inches (2 to 4 cm), or less in preterm infants, until blood can be aspirated. If the catheter is advanced too far, infusing hypertonic solutions directly into the liver may lead to irreversible damage **FIGURE 23-13**. If the catheter is advanced into the heart, arrhythmias may develop.
6. Once access is established, flush with 0.5 mL of normal saline and tape the catheter in place.

Description

For an older neonate (after the first week following birth), if emergent IV access is needed but peripheral IV access cannot be obtained, an IO line can be placed, similar to the case for an older child. Take care to choose a small-size line and to avoid traversing the bone.

Signs and Symptoms

Shock

- Hypotension
- Tachycardia (or bradycardia in cases of asphyxia)
- Poor perfusion
- Tachypnea
- Oliguria/anuria
- Hypothermia
- Acidemia
- Weak pulses
- Hepatomegaly, cardiomegaly, and peripheral edema in cardiogenic shock

- Disseminated intravascular coagulopathy

Differential Diagnosis

Shock

- Hypovolemia from acute blood loss or fluid loss
- Polyuric renal failure
- Diarrhea
- Congenital heart disease
- Arrhythmias
- Myocardial ischemia from asphyxia
- Cardiac tamponade
- Pneumothorax
- High intrathoracic pressure from PPV with secondary decreased venous return
- Sepsis
- Cardiac depression
- Vasodilation
- Profound anemia

Transport Management

Shock

- Manage the ABCs.
- Check blood glucose levels.
- Treat the underlying cause.

Anemia

Anemia is defined as a hematocrit value of less than 38% in preterm neonates and less than 42% in term neonates. A neonate with anemia may either be asymptomatic or present with any of the following signs or symptoms, depending on the cause: tachycardia, pallor, petechiae/purpura, jaundice, hepatosplenomegaly, respiratory distress, hydrops, heart failure, visible bleeding/hematoma, cyanosis, shock, or acidosis.

Causes of anemia in a neonate can be categorized based on whether they result from increased destruction, decreased production, or loss of red blood cells (RBCs). Causes of increased destruction include hemolysis from RBC defects (hereditary spherocytosis, glucose-6-phosphate dehydrogenase [G6PD] or pyruvate kinase deficiency, or thalassemia) and immune processes (Rh incompatibility, ABO incompatibility, maternal lupus, maternal penicillin use). Disseminated intravascular coagulopathy, hemangiomas, vitamin E deficiency, and arterial stenosis can also lead to hemolysis. Decreased production of RBCs can be seen in infections such as parvovirus, rubella, or cytomegalovirus; congenital leukemia; Diamond-Blackfan syndrome; and trisomy 21 (Down syndrome). Hemorrhage can occur in utero, with fetomaternal hemorrhage or twin-twin transfusion, or in the perinatal or neonatal period with abruptio placentae, placenta previa, velamentous insertion of the cord on the placenta, cord rupture, fetomaternal bleeding, cephalohematoma, subgaleal/intracranial hemorrhage, splenic hemorrhage, intracranial hemorrhage, necrotizing enterocolitis, or traumatic injury.

Rh incompatibility is a serious situation that can have dire consequences. If a pregnant woman’s blood type is Rh negative and her fetus’s blood type is Rh positive, the woman can become sensitized to the Rh-positive blood, making antibodies against it, when small amounts of fetal blood enter her circulation. Rhogam is routinely given to Rh-negative mothers during and immediately after delivery to minimize this risk, but sensitization still occurs, such as after unrecognized spontaneous early miscarriages. In subsequent pregnancies, if the fetus is Rh positive, maternal antibodies can cross the placental barrier and destroy the Rh-positive fetal RBCs, leading to severe anemia and ultimately heart failure and hydrops.

Management of anemia includes managing the ABCs and obtaining IV access (optimally two sites). Initially, the following lab values should be obtained in consultation with a physician: a blood type and crossmatch, CBC, **peripheral blood smear** (which allows the lab to microscopically examine the structure of the blood cells), reticulocyte count, **Coombs test**, bilirubin level, liver function tests, a **TORCH screen** (a blood test that checks for several infections in a newborn, including Toxoplasmosis, Other agents, Rubella, Cytomegalovirus, and Herpes simplex), cultures of scrapings from any vesicular lesions, electrolyte levels, and coagulation factors. (TORCH is a set of infections to which pregnant women are susceptible that result in fetal deformities.)

The neonate with anemia may be in shock. In such patients, volume resuscitation with a 20 mL/kg bolus of normal saline followed by the administration of blood is crucial.

If the anemia is chronic, the infant is at risk of volume overload after transfusion. The supervising physician may need to perform an exchange transfusion to avoid cardiac collapse. If coagulopathy is suspected, use packed RBCs and fresh-frozen plasma.

Hyperbilirubinemia

Hyperbilirubinemia, a condition in which an excess of bilirubin develops in the blood, is commonly seen in newborns. Hyperbilirubinemia frequently leads to **jaundice**, the deposition of bile pigments in the skin. Approximately 60% to 80% of term infants and nearly 100% of preterm infants will have clinical jaundice. This condition reflects the immaturity of the bilirubin conjugating enzymes in the liver as well as the increased RBC turnover that occurs in newborns. The jaundice often appears after the first day and for the most part is self-limiting. In term infants, it usually peaks during days 3 to 5 and then slowly begins to improve. In premature infants, this process may take longer. Occasionally, bilirubin levels may be high enough to cause severe and permanent sequelae as the bilirubin becomes deposited in the brain cells, leading to bilirubin-induced neurotoxicity.

Pathophysiology

Bilirubin is produced in the reticuloendothelial system in the spleen, liver, and bone marrow; it is the end product of heme degradation.

Heme is produced by the breakdown of hemoglobin and other hemoproteins. When heme oxygenase releases an equimolar amount of carbon monoxide, heme is converted to biliverdin (water soluble). Biliverdin is then converted to unconjugated bilirubin (lipid soluble) by biliverdin reductase. The unconjugated bilirubin is bound to albumin and transported to the liver, where it is conjugated with glucuronic acids by the enzyme uridine diphosphate-glucuronyl transferase (UDPGT) to form monoglucuronides and diglucuronides, or conjugated bilirubin (water soluble). The conjugated bilirubin is then excreted in the bile and metabolized by intestinal bacteria to form urobilin (excreted via the urine) and stercobilin (excreted in stools). The conjugated form can also be deconjugated by bacteria to create unconjugated bilirubin, which is reabsorbed in the intestine and transported back to the liver, thus completing the enterohepatic circulation.

Physiologic Jaundice

In most infants, the total serum bilirubin does not exceed 12 mg/dL, with levels peaking at about 3 to 5 days after birth. Breastfed babies have a higher risk for exaggerated physiologic jaundice. Breastfeeding jaundice is self-limiting and resolves as maternal milk supply increases and infant feeding becomes well established. Occasionally, jaundice may persist beyond 2 weeks of age in breastfeeding infants, a condition sometimes referred to as breast milk jaundice.

Pathologic Jaundice

Pathologic jaundice is defined as jaundice of greater than 12 to 15 mg/dL in healthy term neonates, or a rate of rise greater than 0.2 mg/dL/h or greater than 5 mg/dL in 24 hours. The etiology of pathologic jaundice must be appropriately investigated **TABLE 23-12**.

TABLE 23-12 **Etiology of Pathologic Jaundice**

Unconjugated Hyperbilirubinemia	Conjugated Hyperbilirubinemia

Increased production of bilirubin
• Physiologic jaundice
• Hemolytic process
  ◦ Immune mediated (ABO or Rh incompatibility)
  ◦ Non-immune mediated (spherocytosis, G6PD deficiency, disseminated intravascular coagulation)
• Polycythemia
• Cephalohematoma or bruising
	Obstruction of the biliary system
	• Biliary atresia
	• Choledochal cyst
	• Alagille syndrome
	Infections
	• TORCH
	• Sepsis, urinary tract infection
	Acute liver injury
	• Ischemia, hypoxia, acidosis

Decreased hepatocellular uptake or conjugation
• Physiologic jaundice
• Prematurity
• Breast milk jaundice
• Congenital hypothyroidism
• Enzyme deficiencies
  ◦ Crigler-Najjar syndrome
  ◦ Gilbert syndrome
	Parenteral nutrition–associated cholestasis
	Defect of bile acid synthesis or transport
	Metabolic liver disease
	• Tyrosinemia
	• Alpha-1 antitrypsin deficiency
	• Galactosemia
	• Mitochondrial liver disease

Abbreviations: G6PD, glucose-6-phosphate dehydrogenase; TORCH, toxoplasmosis, other agents, rubella, cytomegalovirus, and herpes simplex

© Jones & Bartlett Learning.

Conjugated hyperbilirubinemia, also known as cholestasis, is always pathologic. It occurs when there is impaired bile formation or interrupted bile flow in the intrahepatic or extrahepatic biliary system. Prolonged jaundice beyond 2 weeks of age or an increase in the level of direct (conjugated) bilirubin suggests cholestatic jaundice and always requires investigation. The most common cause of this condition is biliary atresia.

Acute bilirubin encephalopathy occurs when bilirubin deposition occurs in the basal ganglia, hippocampus, cerebellum, and nuclei of the floor of the fourth ventricle, leading to a loss of neurons and gliosis. It is likely to occur when bilirubin levels exceed 30 mg/dL, but rarely presents in infants with bilirubin levels less than 20 mg/dL. Evidence of bilirubin toxicity can be detected by auditory-evoked potentials. The term *kernicterus* is generally reserved for the chronic and permanent sequelae of bilirubin-induced neurologic dysfunction.

As better diagnostic and genetic tests become available, more of these conditions are being identified early.

Assessment

Serum bilirubin levels should be obtained if jaundice is suspected. Hyperbilirubinemia is one of the most common reasons for readmission of the newborn to the hospital within the first 2 weeks after birth. Because newborns are often discharged from the hospital within 48 hours of birth, jaundice tends to be an outpatient problem.

Initial steps in evaluating a newborn with jaundice involve differentiating between unconjugated and conjugated hyperbilirubinemia. Appropriate laboratory tests and imaging studies may be used to create a differential diagnosis. A detailed history, including prenatal care, maternal blood tests, and birth history, may help identify potential risk factors. A family history, results of a newborn metabolic screening, a thorough abdominal examination (to identify an enlarged liver or spleen), and focused testing will help identify pathologic processes.

Treatment

Phototherapy

Phototherapy entails the use of a visible spectrum of light to treat hyperbilirubinemia in the newborn. It acts by transforming unconjugated bilirubin into water-soluble photo-isomers that can be eliminated by the kidney and the liver without needing to be conjugated. The dose of phototherapy is determined by the wavelength of the light (460–490 nm, blue range), the intensity of the light (irradiance), the distance of the newborn from the source of light, and the surface area of the body exposed to the light. The light transforms a bilirubin molecule into structural isomers (lumirubin) or configurational isomers. Configuration isomerization is a reversible but rapid process, whereas structural isomerization is a slower but irreversible process.

Phototherapy represents a simple measure that is effective in reducing the bilirubin levels and under most circumstances can reduce the need for an exchange transfusion. With appropriately delivered phototherapy, a significant reduction in the infant's total serum bilirubin can be achieved.

IV Immunoglobulin Therapy and Exchange Transfusion

IV immunoglobulin therapy may be used in infants with hemolytic jaundice. It has been shown to decrease the need for exchange transfusion.

When necessary, a double-volume exchange transfusion can be carried out in specialist centers to treat hemolytic jaundice. In this procedure, the baby's blood is exchanged twice, slowly for type O-negative blood. An exchange transfusion may be necessary in cases involving Rh isoimmunization or other hemolytic processes.

Gastrointestinal Conditions

Any part of the gastrointestinal tract may have congenital anomalies. The most common of these lesions noted at birth are **atresia** (complete absence of a lumen), stenosis (narrowing), duplication of loops of bowel, and functional obstruction.

Presenting features may include increased salivation; choking with feeding; cyanosis; vomiting, especially if bile stained; abdominal distention; blood in stool or failure to stool; lethargy; or irritability. Physical findings may include a distended, discolored (erythematous), tender abdomen; absent bowel sounds; or lethargy and poor perfusion. Important principles include the knowledge that bilious (green or yellow) vomiting is considered an indication of an obstruction until proven otherwise, passage of meconium does not rule out an obstructed bowel, and an obstructed bowel can lead to perforation and peritonitis.

Abdominal Wall Defects

Gastroschisis and omphalocele are abdominal wall defects that can be distinguished by their presentations **TABLE 23-13**.

TABLE 23-13 Comparison of Gastroschisis and Omphalocele

	Gastroschisis	Omphalocele
Definition	Centrally located, full-thickness abdominal wall defect	Herniation of abdominal contents into base of umbilical cord

	Gastroschisis	**Omphalocele**
Features	• 0.75- to 1.5-inch (2- to 4-cm) defect • Right side of cord • Intact umbilical cord • Uncovered intestine, thick, edematous, matted • Liver, spleen in normal positions	• Different sizes • Protective membrane covers the abdominal contents • Elements of umbilical cord course over the sac and come together at the top to form a normal umbilical cord • Large omphalocele may contain the liver and/or spleen
Associated abnormalities	Isolated defect	25% to 40% of infants have associated chromosomal, cardiac, neurologic, genitourinary, skeletal, or other gastrointestinal defects

© Jones & Bartlett Learning.

- **Gastroschisis** is a full-thickness defect of the abdominal wall, usually to the right and adjacent to the intact umbilical cord. Variable amounts of edematous intestine and stomach tissue extrude from the defect (the liver and spleen are normally situated in the abdomen). The extruded intestine does not have a protective covering. The reported incidence of this defect is 1 in 2,000 births.
- **Omphalocele** is a herniation of the abdominal contents into the umbilical cord. A protective membrane covers the herniated contents (unless ruptured during the birth process).

Gastroschisis is usually an isolated defect, whereas omphalocele has an association with a variety of congenital defects, such as congenital diaphragmatic hernia and other anomalies.

Ideally, infants with gastroschisis or omphalocele should be delivered at a regional perinatal center that has immediate access to a neonatal intensive care unit and pediatric surgery. However, occasionally these infants are born at remote locations even when their condition may have been diagnosed prenatally. Under those circumstances, rapid newborn transport should be provided, and care coordinated between obstetricians, pediatricians, and surgeons.

Immediate care includes initial resuscitation, then placing the abdominal contents in a clear sterile bag to cover and protect the exposed contents, thereby limiting fluid and protein loss and preventing hypothermia. Handling of the bowel should be minimized to decrease vascular compromise. Hypothermia, dehydration, sepsis, and injury to the bowel will lead to a poor outcome for the neonate. With a large defect, the infant may be placed right side down to minimize stretching of the mesenteric vessels. The intestines should be visualized throughout the transport; if they begin to look dusky, they should be repositioned to optimize blood flow.

A nasogastric or orogastric tube should be maintained at low intermittent suction. A wide-bore double-lumen **Replogle tube**, if available, is ideal for this purpose **FIGURE 23-14**. A Replogle tube is used for gastric decompression in infants with gastrointestinal issues; for an infant, usually an 8F size suffices and is connected to low intermittent suction to collect gastric secretions.

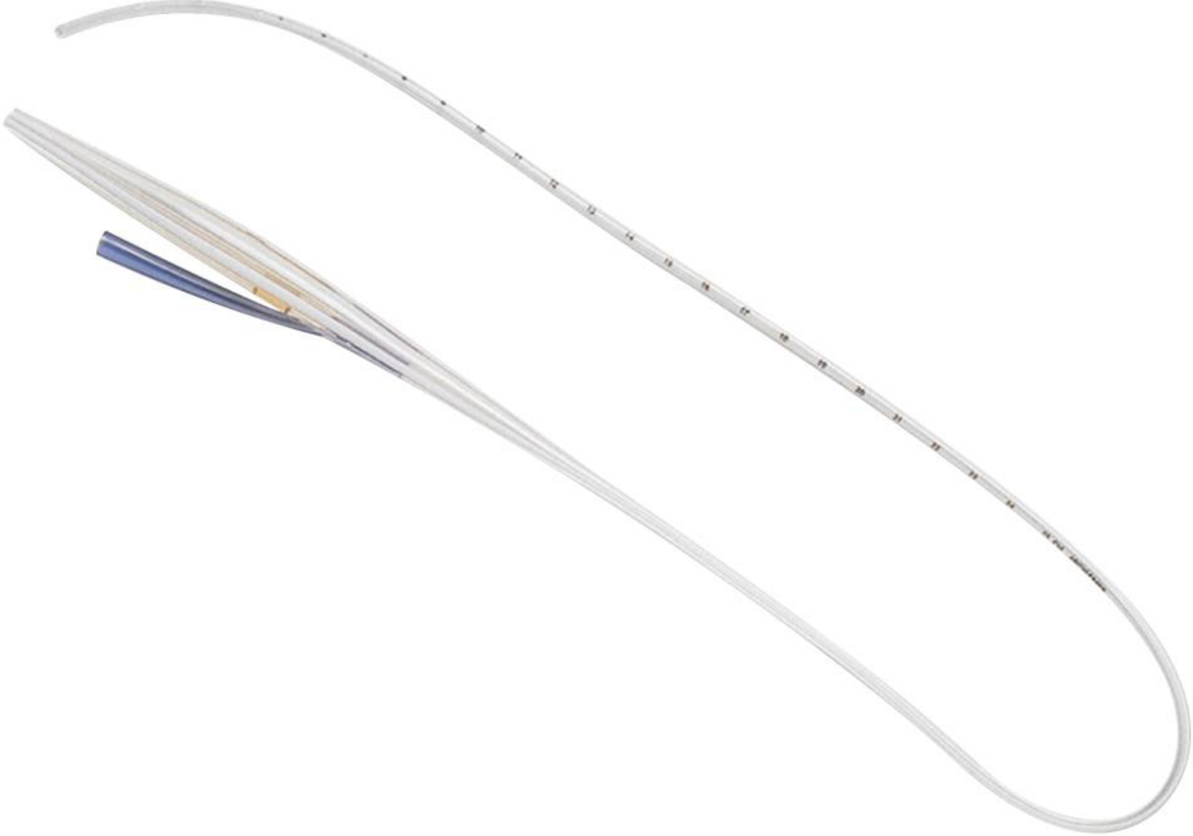

FIGURE 23-14 A Replogle tube.

Courtesy of Covidien.

Vascular access should be maintained in any infant with a gastroschisis or omphalocele. Generous IV fluids consisting of $D_{10}W$ are initiated at approximately 120 to 150 mL/kg/d because of the increased fluid loss and third space deficits associated with both of these conditions. CCTPs should provide hemodynamic support with fluids and pressors, if necessary. Broad-spectrum antibiotics should be administered before initiating the transport given the increased risk of infection in these infants.

An intact omphalocele is a less urgent surgical problem than a gastroschisis or ruptured omphalocele because the intact membrane conserves heat and protects the intestine. The sac should be carefully protected. With any of these conditions, however, surgical consultation should be obtained as soon as possible, initially by telephone, so that a surgical plan can be developed. Provide rapid transport to an appropriate pediatric surgical facility.

Gastrointestinal Obstruction and Vomiting

The causes of vomiting can be differentiated based on the presence or absence of bile, which turns the vomitus green. Presence of bile must be treated as a surgical emergency until gastrointestinal obstruction, especially **malrotation** of the intestine, has been ruled out. Bile-stained vomiting may occasionally be seen without intestinal obstruction, such as with a septic ileus. In these situations, it may present without abdominal distention and does not continue to recur.

The differential diagnosis of bilious vomiting includes malrotation with volvulus, intestinal atresia, and annular pancreas. The differential diagnosis of nonbilious vomiting includes esophageal atresia, gastroesophageal reflux, overfeeding (excessive volume of feed), milk or formula intolerance, sepsis, and obstructive lesions above the ampulla of Vater such as pyloric stenosis or partial intestinal obstruction.

Esophageal atresia (a congenital defect in which the esophagus ends in a blind pouch) is suspected when the infant presents with increased salivation and chokes on feeding. Vomitus with esophageal atresia is never bile stained, and the infant often develops respiratory distress from aspiration. Examine the infant for other abnormalities such as anal atresia (an abnormal or absent anal opening). The diagnosis of esophageal atresia is further substantiated by inability to pass a nasogastric tube to the stomach; the tube coils in the esophageal pouch in patients with this defect. Stomach contents may be obtained when suctioning the ET tube of an intubated infant with esophageal atresia with a tracheoesophageal fistula. When trying to document an esophageal atresia, use as large a tube as will pass through the nares.

Atresia can be confirmed by obtaining a chest radiograph that includes the neck and upper abdomen. Note the presence or absence of air in the stomach: A lack of air in the stomach suggests that the patient has an esophageal atresia without a communication between the trachea and the lower esophagus, whereas the presence of air in the stomach suggests the presence of such a connection. Note the presence of other vertebral and/or rib anomalies suggesting **VATER syndrome** (Vertebral anomalies, Anal atresia, Tracheoesophageal fistula and/or Esophageal atresia, and Renal and radial anomalies). Diagnosis of atresia requires a high index of suspicion for this condition.

During transport of the neonate with esophageal atresia, position the neonate with the head elevated at a 30° angle, place a suction catheter in the upper pouch, and provide intermittent suction. Neonates often do not need to be intubated if the airway is kept clear of secretions; achieving this goal requires frequent oral suctioning.

Congenital gastrointestinal obstruction should be considered when **polyhydramnios** (extra amniotic fluid) is present. **Proximal intestinal obstruction** is an obstruction at or above the level of the jejunum. Duodenal obstruction may be complete (duodenal atresia) or partial (annular pancreas, duodenal atresia, malrotation, and midgut volvulus). The clinical presentation may include bilious vomiting, minimal dilation of the abdomen, or evidence of intestinal ischemia (bloody mucoid stools). An increased incidence of duodenal atresia is seen in neonates with trisomy 21, with prenatal ultrasonography or abdominal radiograph showing the classic “double-bubble” in which two large collections of gas are present, one in the stomach and the other in the dilated part of the duodenum **FIGURE 23-15**. The rest of the abdomen is generally gasless in complete obstruction.

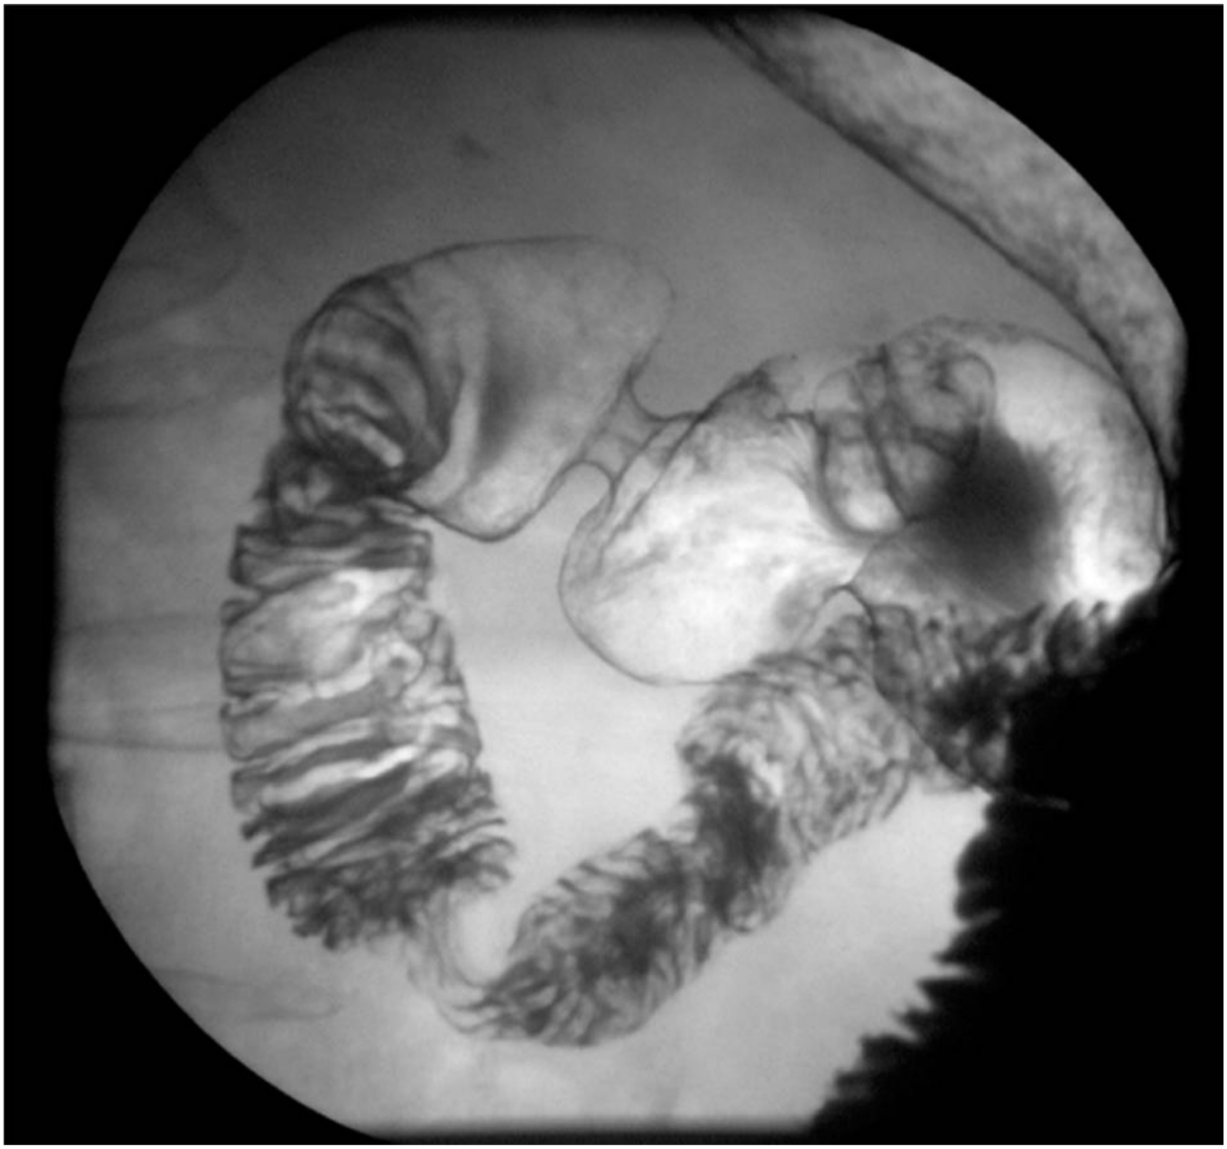

FIGURE 23-15 A fluoroscopic image showing a collection of gas in the stomach and in the duodenum.

© Medical Body Scans/Science Source.

The exact cause of obstruction may not be evident until laparotomy is performed. Malrotation should be considered, as midgut volvulus (twisting of the entire midgut on the superior mesenteric artery pedicle) constitutes a surgical emergency. The ensuing ischemia may result in a nonviable bowel and death, resulting in the phrase known to most pediatricians: “Never let the sun set on bilious emesis.” Management includes establishing IV access, fluid resuscitation, broad-spectrum antibiotics, and urgent laparotomy. When volvulus is suspected, consult the surgeon by telephone before leaving the referring institution so as to expedite the surgical plan for the patient.

Distal intestinal obstruction refers to partial or complete obstruction of the distal small bowel (ileum) or large intestine. Its differential diagnosis includes ileal atresia, meconium ileus (obstruction of the terminal ileum by inspissated meconium), meconium plug or hypoplastic left colon, colonic atresia, and Hirschsprung disease (congenital aganglionic colon). The clinical presentation often includes a distended abdomen, failure to pass meconium in the first 24 to 48 hours after birth, and bilious or nonbilious vomiting. An abdominal radiograph often shows multiple dilated loops of bowel **FIGURE 23-16**. Management considerations include ensuring IV access, hydration, and placement of a nasogastric tube or Replogle tube if available to suction air and avoid further abdominal dilation during transport. Transfer the infant to a pediatric surgical center for specific diagnosis and treatment.

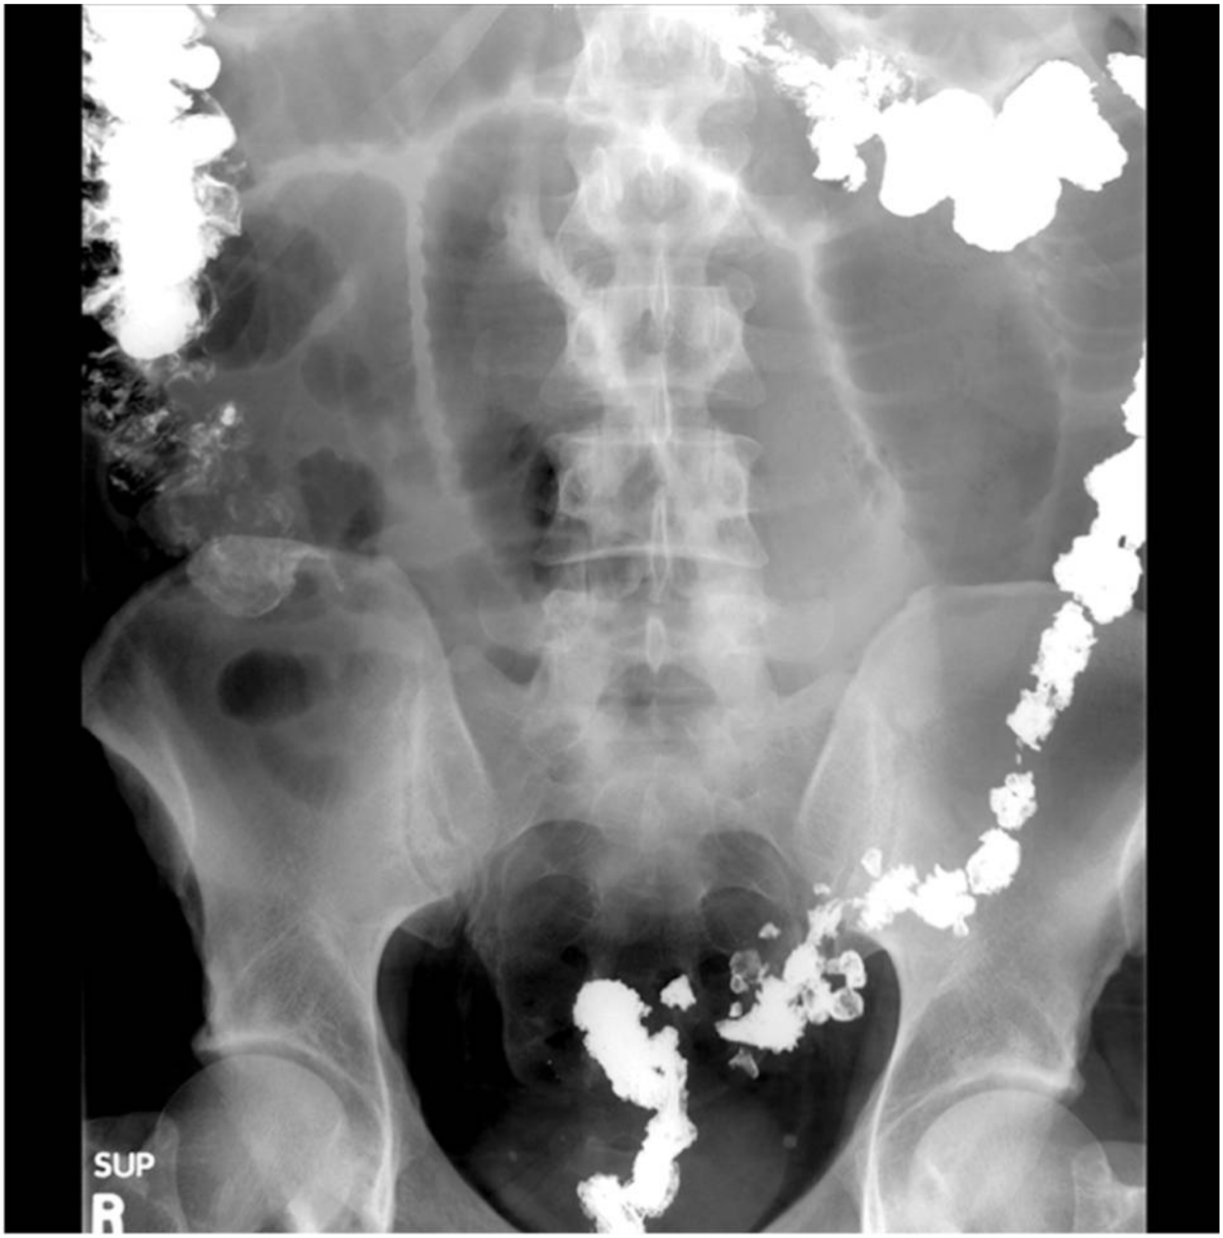

FIGURE 23-16 An abdominal radiograph after a barium enema showing multiple dilated loops of bowel.

Imperforate anus is a congenital condition in which the anal opening is either absent or displaced. Diagnosis requires inspection of the anal opening and should be made in the delivery room. If the condition is diagnosed shortly after birth, the infant is usually asymptomatic, but a delay in diagnosis can lead to progressive abdominal distention and perforation. After this diagnosis is made, health care providers should maintain NPO status, establish IV access, administer maintenance IV fluids, and place a nasogastric tube or Replogle tube and provide low intermittent suction to minimize abdominal distention. In addition, transfer to a surgical center for evaluation and treatment should be arranged quickly. Infants with imperforate anus also have a higher rate of CHD and other anomalies that may further complicate the transport.

Hirschsprung disease is a congenital anomaly in which a portion of the intestine lacks ganglion nerve cells. As a result, normal peristalsis does not occur, and stool backs up. If undiagnosed, this condition can lead to toxic megacolon. Signs include decreased stooling, abdominal distention, and, in later stages, shock. Fluid resuscitation and transport to a referral center with pediatric surgery capability can be lifesaving.

In each of these transports, thermoregulation of the neonate should be maintained and close monitoring of vital signs, including oxygen saturation, heart rate, respiratory rate, BP, and strict intake/output, should occur.

Differential Diagnosis

Proximal Intestinal Obstruction

- Duodenal atresia
- Annular pancreas
- Malrotation
- Midgut volvulus

Transport Management

Proximal Intestinal Obstruction

- Maintain thermoregulation.

- Closely monitor vital signs, including oxygen saturation, heart rate, respiratory rate, and BP.
- Ensure strict intake/output.

Acute Intestinal Perforation

Perforation of the bowel can be caused by an obstructed bowel; **necrotizing enterocolitis (NEC)**, a disorder seen predominantly in premature infants; or iatrogenic perforation (may be caused by suprapubic bladder aspiration or paracentesis). Perforation may also occur spontaneously. It is sometimes seen in preterm infants in association with indomethacin use, especially when this medication is combined with hydrocortisone or dexamethasone therapy.

The clinical presentation of intestinal perforation includes progressive abdominal distention, respiratory distress, hypotension, and acidosis (mixed metabolic and respiratory). Both physical examination and laboratory tests are helpful in making this diagnosis. Radiographic studies will show free air in the abdomen, whose presence can be confirmed by a cross-table lateral or left lateral decubitus view (right side up).

NEC presents with abdominal distention, feeding intolerance, and grossly bloody stools. The infant often appears septic. The diagnosis is confirmed by an abdominal radiograph showing **pneumatosis intestinalis** (air in the bowel wall), and may be suspected when an abnormal gas pattern, ileus, and a fixed sentinel loop are seen on radiographs. Other features include intrahepatic portal venous gas.

During transport of a neonate with suspected bowel perforation, maintain NPO status. A nasogastric or Replogle tube should be placed and low intermittent suction provided to assist with decompression of the bowel. These infants are at high risk of shock and severe metabolic acidosis secondary to inflammation and vascular leak. Establish vascular access and provide 10-mL/kg normal saline boluses as needed to support perfusion and BP, in addition to maintenance fluids. Blood cultures and CBC should be drawn and broad-spectrum antibiotics initiated prior to leaving the referring facility. In addition, these neonates often develop apnea, so maintain a low threshold for intubation before beginning the transport. If the infant develops recurrent apnea en route, intubate the infant quickly to avoid further abdominal distention from bag-mask ventilation. Provide transport to an appropriate pediatric surgical facility for further evaluation and surgical intervention. If intestinal perforation is confirmed, notify the surgeon before leaving the referring institution so a surgical plan for the patient can be expedited.

Hematemesis and bleeding from the upper gastrointestinal tract may be seen in a nasogastric tube aspirate or be associated with vomiting. Such blood is generally bright red, although brown blood may be seen if the bleeding is slow or starts high in the intestines. The differential diagnosis in such cases includes idiopathic bleeding (no clear cause; generally resolves within a few days), swallowed maternal blood (accounts for approximately 10% of cases; the infant may swallow blood during a cesarean section, and occasionally during a vaginal delivery), nasogastric trauma from a nasogastric tube, stress ulcer (often seen in sick neonates), coagulopathy (hemorrhagic disease of the newborn [vitamin K deficiency] or disseminated intravascular coagulation), bleeding Meckel diverticulum, NEC, intestinal fissure, formula intolerance (usually cow's milk protein allergy), maternal bleeding nipples in breastfed infants, or volvulus.

Volvulus is an abnormal twisting of the intestine. It can lead to gangrene and death of the affected segment of intestine, intestinal obstruction, perforation peritonitis, and death of the patient. Midgut volvulus occurs in infants with malrotation of the bowel during fetal development. Segmental volvulus can occur at any age and may be caused by abnormal intestinal contents (meconium ileus); sigmoid volvulus usually results from a dilated rectosigmoid on a narrow pedicle.

Volvulus often has a sudden onset. Its symptoms and signs may include abdominal pain, nausea, vomiting, and blood in the stool. Intestinal volvulus is a surgical emergency, requiring release of the abnormal twisting so as to ensure a normal blood supply. If this condition is suspected, keep the patient on NPO status, establish IV access, begin maintenance fluids, decompress the intestines with a nasogastric tube or Replogle tube, provide low intermittent suction, and expedite transfer to a center with pediatric surgical services.

Intussusception

Intussusception is the telescoping of one segment of intestine into another adjacent distal segment of the intestine. Intussusception is the most common cause of intestinal obstruction in children between 3 months and 6 years of age; it is extremely rare in children younger than 3 months of age or in older children and adults. This condition can present with passage of bloody stool, often described as currant jelly stool due to its resemblance to that food.

Signs and Symptoms

Acute Intestinal Perforation

- Progressive abdominal distention
- Respiratory distress
- Hypotension
- Acidosis (mixed metabolic and respiratory)
- Feeding intolerance
- Grossly bloody stools

Differential Diagnosis

Acute Intestinal Perforation

- Obstructed bowel
- Necrotizing enterocolitis
- Iatrogenic perforation
- Spontaneous perforation

Transport Management

Acute Intestinal Perforation

- Maintain NPO status.
- Monitor for development of apnea.
- Intubate the infant if recurrent apnea develops during transport.

When intussusception is suspected, keep the patient on NPO status, establish IV access, begin maintenance fluids, decompress the intestines with a nasogastric tube or Replogle tube, provide low intermittent suction, and provide rapid transfer to a center with pediatric radiology and surgical services. An intussusception may be reduced by enema, but frequently needs open reduction to ensure its final resolution.

Diarrhea

Diarrhea in a neonate is unusual because the infant still has maternal immunoglobulins that help minimize the child's risk of contracting diarrheal illness in the first few weeks of life. When transferring a neonate with diarrhea, maintain the infant on NPO status, establish IV access, and provide fluid resuscitation as clinically indicated. Continue maintenance fluids en route to minimize further dehydration and hypoglycemia. Monitor the patient's vital signs throughout the transport, and make efforts to maintain normothermia in the infant.

Transport Management

Diarrhea

- Maintain NPO status.
- Provide maintenance fluids.
- Monitor vital signs.
- Maintain normothermia.

Infectious Diseases/Sepsis

Neonates are particularly susceptible to becoming compromised by serious infectious diseases because their immune system is not fully developed. Signs of infection in a neonate include decreased activity (lethargy), hypothermia, hypoglycemia, poor perfusion, low BP, and apnea. Neonates are at higher risk of infection with group B *Streptococcus* and gram-negative bacteria, which frequently respond to ampicillin and gentamicin. Viral illness, however, can lead to dire illness in a neonate.

Primary assessment of a neonate with a suspected infectious disease includes a blood culture, urine culture, and lumbar puncture. These measures are followed by administration of broad-spectrum antibiotics. A chest radiograph is taken if the infant has respiratory symptoms.

Regardless of the causative organism, it is important to support the infant’s cardiorespiratory state and aggressively provide fluid resuscitation if signs of shock are present. Monitor vital signs and maintain normothermia while transferring the patient to a center that can care for a critically ill neonate, because the infant’s condition can deteriorate rapidly.

Hyperthermia/Hypothermia

Hyperthermia (temperature greater than 99.5°F [37.5°C]) in a neonate is usually caused by overbundling or exposure to excessive heat, but it can also be seen with herpes simplex infection or dehydration. Hypothermia in the neonate, defined as a decrease in body temperature to less than 97.5°F (36.4°C), occurs in all climates, but is more common during the winter months. It can also be an early sign of sepsis.

Neonates have increased surface area-to-volume ratio relative to adults, making them extremely sensitive to environmental conditions. This is especially the case immediately after delivery, when the neonate's body is wet. An increase in metabolic function in an attempt to overcome the heat loss can cause hypoglycemia, metabolic acidosis, pulmonary hypertension, and hypoxemia. Infection should be considered as an etiology in any hypothermic neonate.

Hypothermic neonates are cool to the touch, initially in the extremities; as their body temperatures drop, however, their skin becomes cool all over. The infant may also be pale and have acrocyanosis. The hypothermic neonate may present with apnea, bradycardia, cyanosis, irritability, and a weak cry. As the body temperature decreases, the neonate may become lethargic and obtunded. In severely hypothermic infants, the face and extremities may appear bright red. **Sclerema** (hardening of the skin associated with reddening and edema) may be seen on the back, on the limbs, or all over the body. Thermal shock, disseminated intravascular coagulopathy, and death may occur in more serious cases.

Preventive measures include warming your hands before touching the infant, using prewarmed blankets and equipment, and placing a cap on the neonate's head (the head is the largest source of heat loss). The critically ill neonate, once stabilized, should be placed in a prewarmed incubator or, if none is available, covered with warm blankets for transport. Recent studies in neonates with hypoxic ischemic injury indicate outcomes are improved when the infant is maintained in a state of mild therapeutic hypothermia within 6 hours of birth. This approach is not recommended in the field, although it is certainly prudent to prevent hyperthermia. Maintain the infant at the lower margin of normal temperature (axillary temperature no higher than 97.5°F [36.4°C]).

Toxic Exposure

Most toxic exposures in neonates result from transplacental exposure (eg, maternal alcohol or narcotic use) or purposeful administration of a substance by another person, such as a well-meaning younger child. The most important principle in managing toxic exposure/ingestion is to stabilize the neonate. Manage the patient's ABCs. Obtain IV access as indicated based on the patient's history and physical exam. Be sure to obtain the history from the sending facility.

In the case of respiratory suppression resulting from narcotics, which is much more likely to stem from chronic maternal exposure, provide respiratory support until the infant is transferred to a tertiary hospital. If respiratory depression is suspected to reflect an acute narcotic exposure, such as when an infant delivers shortly after a dose of maternal narcotic is administered for labor pain control, naloxone 0.1 mg/kg may be administered to reverse the narcotic effect. While the IV route is preferred, intramuscular (IM) administration may be used if necessary. In case of a chronic maternal (and therefore newborn) exposure to narcotics, administering naloxone may precipitate seizures in the infant, potentially causing death; therefore, it is not recommended in this circumstance. When the maternal history is in doubt, acute narcotic intoxication in the infant can be managed by ventilator support, and naloxone administration can and should be avoided.

For additional exposures, including topical exposures, contact the local Poison Control Center. The experts at this center can guide CCTPs regarding the appropriate response to myriad exposures.

Trauma/Birth Injuries

Injuries to the infant that result from mechanical forces (ie, compression, traction) during the birth process are termed birth trauma. Significant birth injury accounts for fewer than 2% of neonatal deaths and stillbirths in the United States. It still occurs occasionally and unavoidably, resulting in an average of 6 to 8 injuries per 1,000 live births. Hypoxic injury may coexist with mechanical injury. Most birth injuries are self-limiting and have a favorable outcome.

Causes and risk factors for birth trauma include macrosomia, prolonged labor, precipitous delivery, breech presentation, instrumentation (forceps/vacuum-assisted delivery), extreme prematurity, and **oligohydramnios** (decreased volume of amniotic fluid during a pregnancy).

Head and Neck Injuries

Most birth injuries self-resolve with time and are not fatal. Birth injuries to the head and neck include two types of benign head and neck injuries: **vacuum caput**, an accumulation of fluid at the site of the vacuum extractor that usually resolves within hours, and **caput succedaneum**, a subcutaneous collection of fluid with poorly defined margins in the scalp, resulting from pressure on the infant’s head during delivery, which usually resolves within a few days. Serious head and neck injuries include subgaleal hematoma, which can spread slowly and result in shock. A subgaleal bleed can present as an ill-defined mass in the dependent part of the head (usually the occipital region); it does not follow suture lines. Significant blood loss may occur with such a hematoma, and the infant may present with shock and acute renal failure if the condition is not promptly identified and treated. **Cephalohematoma** is a subperiosteal collection of blood that may be accompanied by a linear skull fracture. It is most commonly seen in the parietal region and is limited by suture lines. It resolves within a few months, with resulting calcification. A skull fracture may present with a slight depression in the skull, although this may not be obvious secondary to an overlying hematoma.

In addition to the skull findings, these birth injuries may present with anemia and jaundice. If a hemorrhage progresses, it may cause hypotension and shock. A hematoma may also become infected.

Management of head and neck injuries is based on the specific presentation. Blood transfusion may be needed for patients with hemorrhage and anemia. Phototherapy (light therapy to reduce bilirubin levels) is needed for jaundice based on the bilirubin level. If the neonate is in hypovolemic shock from excessive blood loss, manage the ABCs and treat for shock, focusing on volume resuscitation and admission to a neonatal intensive care unit (NICU).

Nerve Injuries

Nerve injuries often occur because of hyperextension or overstretching during delivery, especially with breech presentation. The nerve injuries incurred during the birth process can range from peripheral nerve branch injury to major spinal cord injury. Most nerve injuries do not require any immediate intervention.

Nerve injuries that need immediate attention and possible transfer to a facility that can provide a higher level of care include recurrent laryngeal nerve injury, which causes paralysis of the vocal cords, unilaterally or bilaterally. This injury presents with respiratory distress, stridor, or desaturation. It may be associated with intracranial bleeding. In an infant in whom such an injury is suspected, visualize the vocal cords by direct laryngoscopy. Intubate in the event of bilateral vocal cord paralysis. Do not feed the neonate to avoid the risk of aspiration during transport.

Vaginal breech delivery poses the greatest risk factor for spinal cord injury. This injury frequently presents with a loud “snap” sound at the delivery. It may be associated with epidural hemorrhage, loss of motor function distal to the injury, temperature instability, and loss of bladder and bowel function. In such a case, immobilize the head and restrain the neonate. If the nerve injury impairs spontaneous respiration, intubate and provide PPV until the infant can be transferred to an appropriate health care facility.

Bone and Other Injuries

The clavicle is the most common site of fracture in a newborn. Risk factors for such an injury include a large infant, shoulder dystocia, and use of instrumentation during delivery (especially forceps). A fractured clavicle itself does not need any urgent intervention, and should heal within 7 to 10 days as long as the motion of the arm is limited. However, a rare complication of a fractured clavicle is a pneumothorax. If the neonate presents with tachypnea or increased work of breathing, consider pneumothorax as the etiology. See the section on pneumothorax for information on management of this condition.

Fractures of the humerus or femur are uncommon birth injuries. Manage these injuries by splinting the arm or leg and transferring the neonate to a pediatric orthopaedic center.

Intra-abdominal injuries during birth are rare but often present as shock and blue discoloration of the abdominal wall. Treat the patient for shock, and ensure that a hematocrit, type and crossmatch, and, if possible, abdominal ultrasonography have been performed at the referring facility before transferring the infant to a hospital with pediatric surgical support.

Finally, soft-tissue injuries include abrasions, lacerations, and ecchymosis. These injuries mostly need routine care.

Transport Management

Bone and Other Injuries

- Monitor for pneumothorax; treat if present.
- Treat for shock.

Abuse/Maltreatment

Shaken baby syndrome is the most common cause of death in cases of child abuse. Shaking of a baby may tear bridging veins in the brain, lead to a subdural hematoma, or cause a hypoxic injury. Most often, the physical exam will not identify significant findings that indicate the presence of this condition. It should be suspected in a previously well infant who presents with nonspecific signs such as feeding intolerance, irritability, and vomiting. Severe cases may even present with seizures or apnea secondary to intracranial hemorrhage. Other maltreatment includes blunt trauma to the abdomen, burns, bruising, and skeletal injuries. The management for these injuries is again based on presentation.

Obvious extremity fractures should be stabilized, with attention given to maintaining circulation to the affected extremity. Fluid resuscitation may be needed if bleeding has occurred. Respiratory support may be needed if intracranial hemorrhage or trauma to the upper airway is present. In patients with severe burns, the affected areas should be protected with sterile material and IV fluids initiated because of the increased insensible water loss that occurs through the burned skin. The CCTP’s goal is to stabilize the neonate and transport the patient safely to a health care facility where further workup and treatment may be done.

Neurologic Conditions

Seizures

Seizures represent the most distinctive sign of neurologic disease in the neonatal period. They may be identified by direct observation. A **seizure** is defined as a paroxysmal alteration in neurologic function (ie, behavioral and/or autonomic function); it often manifests with apnea in a term neonate. It is important to distinguish seizures from other motor phenomena (eg, jitteriness, myoclonic activity) that could be confused with them. Seizures represent a relative medical emergency because they are usually a sign of a serious underlying abnormality. It is critical to recognize neonatal seizures and to determine their causes because they may interfere with cardiopulmonary function, interrupt feeding, affect metabolic function, and, if prolonged, cause brain injury.

Jitteriness is often confused with a seizure **TABLE 23-14**. Jitteriness is characteristically a disorder of the newborn and is rarely seen at a later age. This condition is most commonly seen with hypoxic ischemic encephalopathy, hypocalcemia, hypoglycemia, and drug withdrawal. In addition, newborns frequently exhibit normal motor activity that could be mistaken for seizures. These myoclonic, dysconjugate eye movements, or sucking movements are often seen when the infant is drowsy or asleep.

TABLE 23-14 **Jitteriness Versus Seizures**

Characteristics	Jitteriness	Seizures
Ocular phenomena (deviation or fixation of the eyes)	Not seen	Commonly associated
Stimulus sensitive (may be triggered by a stimulus)	Yes	No

Characteristics	Jitteriness	Seizures
Dominant movement	Tremor	Clonic jerking
Application of gentle pressure to limb	Stops jitteriness	Does not stop seizures
Autonomic phenomena	Not associated	Common association

© Jones & Bartlett Learning.

A simple classification of seizure types suggests that four essential types can be recognized: subtle, tonic, clonic, and myoclonic. Subtle seizures are characterized by apnea, eye deviation, blinking, sucking, and pedaling movements of the legs. Tonic seizures are characterized by tonic extension of the limbs. Less commonly, with this type of seizure, flexion of the arms and extension of the legs may also occur. Tonic seizures are more common in premature infants, especially in those with intraventricular hemorrhage. Seizures characterized by clonic localized jerking are classified as focal clonic seizures; these types of seizures can occur in both term and premature infants. Lastly, myoclonic seizures are characterized by flexion jerks of the upper or lower extremities, singly or in a series of repetitive jerks.

Causes of neonatal seizures include hypoxic ischemic encephalopathy, intracranial hemorrhage, intracranial infections (meningitis), development defects, hypoglycemia, hypocalcemia, and other metabolic disturbances, frequently as the result of inborn errors of metabolism. You may observe a quiet, often hypotonic infant. The infant may be lethargic or apneic.

Hypoglycemia must be recognized quickly and treated promptly, within a few minutes, to minimize the risk of brain damage. $D_{10}W$ may be given as an IV bolus (2 mL/kg) if the blood glucose level is less than 40 mg/dL. A blood glucose measurement and administration of dextrose in an infant with hypoglycemia may be lifesaving. Recheck the blood glucose level every 30 minutes after treating an infant for hypoglycemia, until the blood glucose level is documented to be stable. An IV bolus of dextrose should be followed by an infusion of $D_{10}W$ to maintain normoglycemia during transport.

The CCTP should continue to monitor the neonate’s vital signs and oxygen saturation throughout transport. Apnea, a symptom that commonly accompanies neonatal seizures, may require intubation and ventilatory support during transport. Phenobarbital (Luminal) and phenytoin (Dilantin) are the two anticonvulsants most often used in neonates. Both drugs may interfere with respiratory and cardiac function, and should be given only in consultation with the supervising physician. Because seizures may be a sign of meningitis, the referring facility should have performed a septic workup and begun antibiotics before the transfer.

Hypoxic Ischemic Encephalopathy

Hypoxic ischemic encephalopathy (HIE) is a neuronal injury caused by oxygen deprivation (hypoxia) or decreased perfusion (ischemia) to the brain. Redistribution of blood occurs during prolonged asphyxia, with more of the cardiac output being delivered to the vital organs (eg, brain, heart, adrenal glands) at the expense of the less vital organs (eg, lungs, gut, kidneys, skin). Multiple-organ dysfunction is common after HIE and may influence the infant’s eventual outcome.

HIE is the single most common cause of seizures in both term and preterm infants. The time of onset for organ dysfunction from HIE, hypoglycemia, and other metabolic disturbances ranges from birth to 3 days postdelivery. In contrast, the time of onset for all other causes of seizures can be from birth to longer than 3 days postdelivery. Infants with HIE often present with decreased tone, poor perfusion, and in more severe situations, hypotension and recurrent apnea.

Management of neonatal HIE includes maintaining adequate ventilation, perfusion, and BP; maintaining adequate blood glucose levels; carefully monitoring fluid intake and output; and adjusting treatment based on the infant’s renal output, oxygen saturation, and ventilation status. The infant’s body temperature should be maintained in the low normal range (97.5°F [36.4°C]) to avoid hyperthermia, which is associated with a worse outcome from HIE. If a newborn with HIE arrives at the tertiary care center within 6 hours of birth, more aggressive therapeutic hypothermia may be offered as a treatment modality under controlled conditions. It is therefore critical to ensure rapid transport of these infants to a center that can provide appropriate therapy.

Lethargy

In infants, lethargy (a decreased level of consciousness during which you are unable to arouse the infant) can be caused by many conditions, but almost always implies a serious, frequently life-threatening underlying condition. Some common causes of lethargy include sepsis, severe hypoxia, severe hypoglycemia, intracranial hemorrhage, and HIE.

Management includes attention to the ABCs, obtaining IV access, ensuring normoglycemia, providing oxygen as needed, initiating antibiotics in conjunction with the supervising physician, and expediting transfer to a tertiary center skilled in dealing with critically ill neonates.

Metabolic Conditions

Metabolic Acidosis

Metabolic acidosis occurs when cations, frequently lactic acid from poor tissue perfusion or toxic by-products of inborn errors of metabolism, build up in the bloodstream. Causes of metabolic acidosis include asphyxia, CHD, sepsis, inborn errors of metabolism, hypovolemia, seizures, bradycardia, hypotension, and toxins. The presentation of metabolic acidosis may include compensatory tachypnea, mottled/gray skin with delayed capillary refill (normally less than 3 seconds), apnea, lethargy, hypertonia or hypotonia, feeding intolerance, seizures, or emesis.

Management of metabolic acidosis includes managing the ABCs; providing adequate oxygenation, ventilation, and hydration; and treating the underlying cause. If adequate ventilation and fluid resuscitation fail to clear the metabolic acidosis, sodium bicarbonate can be given at the following dose: 0.3 × the base deficit on the blood gas analysis × the neonate’s weight in kilograms. If the exact deficit is not known, a dose of 2 mEq/kg can be given. In premature neonates, the dose should be administered over at least 30 minutes to minimize the risk of intraventricular hemorrhage. If an inborn error of metabolism is suspected, stop enteral feeding and initiate IV dextrose to minimize production of toxic by-products. Critically ill neonates often have a mixed metabolic and respiratory acidosis (respiratory acidosis was discussed earlier in this chapter in the respiratory conditions section).

Hypoglycemia

Hypoglycemia, defined as a blood glucose level of less than 40 mg/dL, is a medical emergency; in severe cases, it can lead to brain damage and even death. Hypoglycemia is more common in infants who are either small or large for gestational age, infants of mothers with diabetes, and infants who are stressed. Signs of hypoglycemia include decreased activity, jitteriness, and seizures.

If you suspect hypoglycemia, immediately perform a heel stick to determine the blood glucose level. If hypoglycemia is present, administer IV dextrose (2 mL/kg $D_{10}W$), followed by an infusion of glucose. First administer 60 mL/kg/d $D_{10}W$ to maintain the term neonate's blood glucose level while you contact the regional perinatal center for guidance on the rate and type of IV solution; this can vary based on the infant's gestational and chronological age.

Hypocalcemia

Hypocalcemia is most commonly seen in low-birth-weight infants and can occur after significant stress, as well as in infants whose mothers have diabetes. Significant hypocalcemia can lead to cardiac arrhythmias, seizures, and tetany. In general, calcium infusion is not indicated in an infant unless hypocalcemia is documented.

There are two time frames when hypocalcemia frequently occurs in the neonate. The first is at age 2 to 3 days. The second (late-onset hypocalcemia) is unusual in the United States but may be seen in infants who consume cow's milk or synthetic formulas that are high in phosphorus.

In an infant who has documented hypocalcemia and is younger than 24 hours, administer an IV infusion of 2 to 3 mEq/kg/d of calcium in $D_{10}W$ during transport. If an infant has documented hypocalcemia, is older than 24 hours, and has normal renal function, administer 10% dextrose in 0.25% saline with 10 mEq/kg of potassium chloride in 500 mL during transport.

Inborn Errors of Metabolism

An **inborn error of metabolism** is any of a class of genetic diseases mostly caused by defects in single genes that code for enzymes that facilitate conversion of various substances into others; these defects lead to accumulation of substances that are toxic or interfere with normal function. Many different inborn errors of metabolism are possible, each of which is relatively rare, so a complete review is beyond the scope of this chapter.

Common presenting features of inborn errors of metabolism include lethargy, acidosis, poor perfusion, and hypoglycemia. If such a condition is suspected, stop enteral feeding and start an IV glucose infusion before the critical care transport team begins the patient’s transfer. If a neonate is lethargic and experiences tachypnea (suggesting a metabolic acidosis), start a glucose infusion even if the neonate is normoglycemic. This infusion will help decrease the buildup of toxic by-products produced by the body when the neonate is unable to metabolize nutrients normally.

Congenital adrenal hyperplasia results from a defect in the synthesis of cortisol. An infant with this condition may have virilizing features and problems with sodium loss, depending on which enzyme is deficient. An infant experiencing sodium loss can present with dehydration and shock. Acute treatment includes normalizing electrolytes and fluid balance, and initiating hydrocortisone replacement after consultation with the supervising physician.

Transport Management

Inborn Errors of Metabolism

- If suspected, stop enteral feeding and begin an IV glucose infusion before transfer.

Congenital Adrenal Hyperplasia

- Normalize electrolytes and fluid balance.
- Consider initiating hydrocortisone replacement; consult with the supervising physician.

The Transfer Process for a Neonate

In the well-organized regional referral system, transport of a high-risk neonate proceeds through the following steps:

1. A physician at the referring hospital initiates a request for transport. A physician in the regional control center decides which facility can accommodate the patient and gives the referring physician advice on caring for the neonate until the transport team arrives.
2. A mode of transportation is chosen: ground transportation, helicopter, or fixed-wing aircraft, depending on the patient's status, distance, availability of services, and weather conditions.
3. The transport team is mobilized, the CCTP is provided with any relevant information known about the neonate to be transferred, and equipment is assembled. Optimally, the team will consist of a health care provider with special training in caring for critically ill neonates, a respiratory therapist with similar special training, and a paramedic who has spent a period of apprenticeship or received additional training in transporting an ill neonate. With particularly critical patients, a physician may accompany the team. The equipment used by the CCTP is highly specialized, including appropriately designed ventilation and oxygenation units and an incubator meeting stringent criteria.
4. On arrival at the referring hospital, the transport team helps with further stabilization of the infant if needed, before embarking on transport. Conditions such as hypoxemia, acidosis, hypoglycemia, pneumothorax, shock, and hypovolemia must be treated before leaving the referring hospital. If the infant is suspected of having an infectious disease, appropriate cultures should be obtained prior to transport and early antibiotic therapy initiated. If a contagious disease is suspected, transport personnel should take adequate safety precautions.

5. While stabilizing the infant, the team collects information and materials, including a copy of the mother’s and infant’s medical records and any radiographs, lab results, and medications for the infant. Often transport teams operate on the basis of implied consent, meaning that transport is considered a part of treatment of the life-threatening emergency. Some areas require signed consent before transport is initiated. Awareness of local and state guidelines is important.

Once the infant’s condition is stabilized as much as possible at the referring hospital, transport the patient to the nearest facility that can provide the appropriate level of care. Ideally, someone will contact this facility to discuss the situation and obtain advice regarding care and disposition throughout the process. Complications can arise en route, such as a dislodged breathing tube or development of a pneumothorax. Given this reality, it is critically important to remain vigilant and recognize changes in the status of the infant, such as desaturation or change in color. Quick intervention will help ensure an optimal outcome.

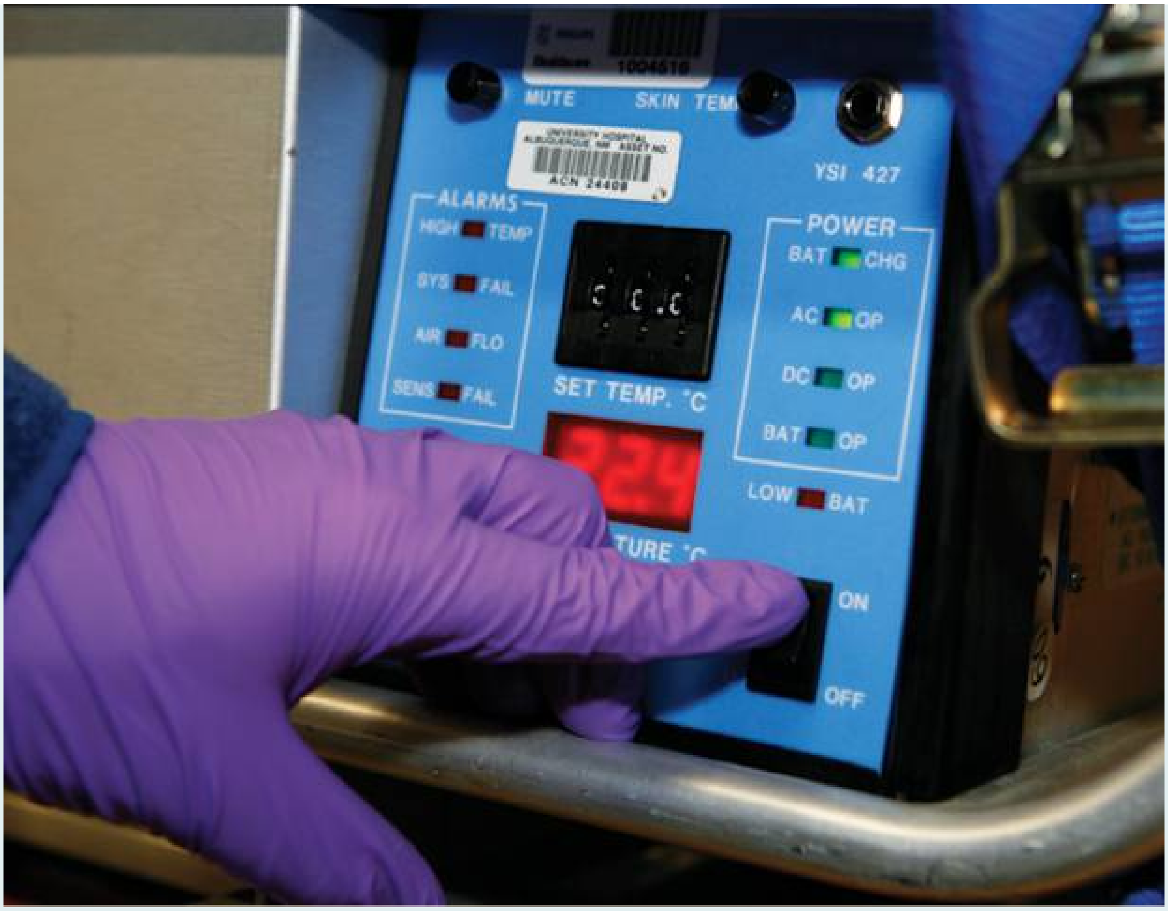
Using an Incubator

An **incubator** is a box with clear walls, a heat source, and portal access in which a neonate can be placed to maintain normothermia and minimize noise stress. An incubator is indicated for transport of infants who weigh less than 10 pounds (5 kg) or are younger than 30 days. When preparing to use an incubator, ensure that the oxygen tank attached to the incubator is full, and that blankets and a bulb syringe are available inside the incubator.

Skill Drill 23-4 shows the steps for using an incubator, which are described here:

SKILL DRILL 23-4 Using an Incubator

Step 1
Plug in the AC power cord.



MUTE

EMPERATURE °C
I ON

Step 4
Check and adjust the set point temperature to 100.4°F (38°C). Do not block or cover the end portions of the incubator.

Step 5
Check the oxygen and air tanks. All tanks should read 2,000 psi.

© Jones & Bartlett Learning.

1. Plug in the alternating current (AC) power cord **STEP 1**.
2. Set the main AC power switch **STEP 2**. The charging indicator will be a constant light if the internal batteries need charging. The light will flicker or go off when fully charged. Battery life is approximately 2 hours.
3. Depress the “controller” switch **STEP 3**. The power failure alarm and AC/DC power mode should light up. The high temperature sensor, heater temperature, and low direct current (DC) alarm should flash. A short beep will be heard at the end of the test. The set point indicator should be illuminated and the temperature reading should indicate 91.4°F (33°C) ± 0.1 for 15 seconds.

4. Check and adjust the set point temperature to 100.4°F (38°C) **STEP 4**. The maximum temperature is 104°F (40°C). It takes approximately 30 minutes to warm up.
5. Do not block or cover the end portions of the incubator.
6. Check the oxygen and air tanks **STEP 5**. All tanks should read 2,000 psi.

Family Communication and Support

Throughout the process of transporting an ill neonate, ongoing communication with the family regarding what is being done for the infant and which care is planned will help allay their fears.

Do not be specific about the infant's chances of survival. Many factors play into morbidity and mortality, and you do not want to be misleading. If family members have questions you cannot answer, be straightforward. Tell them that you do not have a definite answer, but you will help put them in touch with the people who do (most likely people at the center to which the infant is being transferred). Often, just explaining what you are doing and giving the family a realistic time frame in which they should be able to speak to someone at the receiving institution is very helpful. Families usually appreciate being told the name of the receiving physician, if it is known at the time of transfer.

Flight Considerations

Air transport, either fixed wing or helicopter, presents a new set of challenges during care of a neonate and should be managed appropriately. Some of these are listed here:

- **Airway.** It is critical to establish a secure airway before takeoff, because it is extremely difficult to intubate a neonate and assess breath sounds during flight. If this step is necessary while in flight, pay special attention to signs of adequate ventilation and ET tube position, such as condensation on the ET tube, chest rise, and change in color of the $ETCO_2$ indicator.
- **Circulation.** It can also be difficult to hear a heartbeat while in the air. Alternative methods of assessment—such as palpating pulsation on a freshly clamped umbilical cord, or feeling the cardiac movement at the point of maximal intensity—can be helpful.
- **Oxygenation.** The partial pressure of oxygen is decreased at higher altitudes, so additional oxygen may be needed to maintain oxygen saturation in the neonate.
- **Temperature regulation.** Take measures to prevent hypothermia in the infant.

Finally, minimize the neonate's exposure to fuel vapor and noise.

Helicopter transport may be used for medium-distance transfers of up to 150 miles (241 km). This mode may not be appropriate for transporting a neonate because of limited space and the relative inability to carry the necessary equipment, such as an incubator, and additional personnel. There is restricted patient access during flight and patient evaluation may be compromised because of noise and vibrations. The cabin is not pressurized, which may lead to further hypoxic and hypothermic stress.

Fixed-wing (airplane) transport is generally reserved for long distances (more than 150 miles [241 km]). As compared to helicopter transport, the space allocated for patient care is generally adequate. Transport will involve ambulance transportation to the airport, subsequent air transport, and further ambulance transportation to the hospital. It is important to arrange not only the helicopter or airplane, but also the ambulances to and from the airports and the respective hospitals.

Summary

Neonates have a unique anatomy, physiology, and pathology, making care and transfer of such patients challenging but rewarding. The CCTP must be familiar with the special needs of this age group to provide optimal care during transfer to reduce morbidity and improve survival.

CASE STUDY

You and your new partner have stopped for a slice of pizza after a routine transport. While ordering, you receive a call to respond to a local emergency department (ED) for a 3-week-old child with a fever. You and your partner understand that young children in febrile states do not fare well—the pizza will have to wait.

On arrival at the ED, you are met by the charge nurse and attending physician. They report to you that a 20-day-old female was brought in by her mother, who said that the infant was sleepy, refused to eat, and felt warm to the touch. Triage noted that the patient was not responding to external stimuli and presented with a weak cry and delayed capillary refill. The patient was delivered at the same hospital, and records show a normal, cephalic delivery with no complications. In addition, the mother had received prenatal care and only had a history of asthma.

Physical exam of the patient reveals diffuse congestion with mild substernal and intercostal retractions, peripheral cyanosis and mottling, a capillary refill time of 4 seconds, and a rectal temperature of 102°F (38.8°C). The child is nonresponsive to verbal stimulation and grimaces when you perform tactile stimulation. Vital signs show a pulse of 180 beats/min, with atrial tachycardia on the monitor, a BP of 100/40 mm Hg, and an oxygen saturation of 90%. An IV line of normal saline has been established in the left antecubital vein with a 24-gauge catheter, and it appears patent. You estimate the infant's weight to be 8 pounds (4 kg). A CBC was drawn, and revealed a white blood cell (WBC) count of 26,000/mm^3. The serum blood glucose level was 80 mg/dL. All other blood values were normal. No arterial blood gas analysis, chest radiograph, or lumbar puncture has been performed. The attending physician advises you that he has been in contact with the NICU at University Hospital and he has the receiving physician's information.

1. What is your presumptive diagnosis?
2. What are some potential causes of this patient's altered mental status?
3. What are your primary concerns in caring for this patient?

You note that the patient is receiving oxygen by a nonrebreathing mask at a flow rate of 8 L/min. You ask your partner to switch to bag-mask ventilation at a rate of 20 breaths/min as you prepare to contact the receiving facility.

Your partner advises you that the bag-mask ventilation is compliant and there is good chest rise. The patient's oxygen saturation has increased to 95%, with other vital signs remaining unchanged. You contact University Hospital and speak with the receiving physician. After confirming the bed assignment, you confer on your findings. It is agreed that bag-mask ventilation, while effective in the ED, may become a challenge to maintain during the 45-minute transport. You receive an order to perform rapid sequence intubation. Your protocol for intubation includes premedication with atropine, fentanyl, and succinylcholine. The patient is intubated. You are unable to obtain cultures, but due to the high suspicion of serious infection, the referring physician instructs you to administer ampicillin and gentamicin at weight-appropriate doses per *The Harriet Lane Handbook* (a pediatric reference tool).

After administration of 160 mL of normal saline, you note that the infant's BP is 110/70 mm Hg, the pulse is 170 beats/min, and capillary refill is 2 seconds. During transport, your patient's oxygen saturation increases to 98%, the $ETCO_2$ is 43 mm Hg, and her color has improved. However, lung sounds are still diffusely congested. You arrive at the NICU and transfer your patient.

Analysis

Although you are somewhat convinced the infant has sepsis, your concern focuses on the patient's impending respiratory failure due to acute respiratory distress syndrome. In addition, the ventilation-perfusion (V/Q) mismatch is causing acidosis by failing to rid the neonate's body of carbon dioxide.

In addition to hypoxia, you must be aware of other potential causes of altered mental status in neonates—namely, hypoglycemia and seizures. Once the airway is secured, the CCTPs must assess the infant's blood glucose level.

Overall, the most critical aspect of caring for this difficult patient is the ability to secure the airway, control oxygenation, and stabilize hemodynamics.

Two weeks later, you and your partner follow up on this case during a quality assurance (QA) meeting. On admission, the patient received a spinal tap, which was negative, but a blood culture revealed *Streptococcus pneumoniae*, a very common bacterium that causes illnesses ranging from ear infections to meningitis. The patient received 7 days of IV ampicillin and gentamicin and successfully fought off the infection, remaining on a ventilator for 3 days and being discharged after 7 days. Credit was given both to the community hospital, for prompt recognition that this patient was in need of more specialized care, and to the transport unit, which made the decision to aggressively manage the patient's airway.

PREP KIT

Ready for Review

- A newborn is an infant within the first few hours of life; a neonate is an infant within the first 28 days of life. Term newborns are delivered between 37 and 42 weeks' gestation.
- Because short-term and long-term outcomes in infants have been linked to initial stabilization efforts, CCTPs must be knowledgeable about problems that may occur with neonates and understand how to treat them. They must also have the appropriate equipment available to treat neonates, and must carefully consider the neonate's transport plan.
- Newborns differ anatomically and physiologically from young children, and CCTPs must be aware of those differences.
- Neonates become cold easily because of a variety of factors, ranging from their high body surface area-to-body weight ratios to increased evaporative heat loss through their skin. To avoid hypothermia, use prewarmed blankets and equipment, including a prewarmed transport incubator, place a cap on the infant's head, and minimize exposure to cold. While avoiding hypothermia, be careful to also avoid environmentally induced hyperthermia.
- The lungs of neonates are small relative to their body sizes, with little respiratory reserve. Their heads are large in relation to their bodies, resulting in neck flexion and obstruction when the infant is in the supine position. Placing a rolled towel under a neonate's shoulders helps open the airway.
- Neonates are obligate nose breathers and may require an oral airway during transport if they present with obstructive apnea. When positive-pressure ventilation is needed, attempts should be made to maintain physiologic tidal volume breaths.
- Neonates have a high oxygen requirement; they do not tolerate interruptions in oxygen delivery for any length of time, and they

become hypoxic and bradycardic quickly.

- The neonate’s heart rate is an important determinant of cardiac output. Neonates respond to careful volume loading with an increase in cardiac output, but they do not tolerate fluid overload. Changes in the cardiovascular circulation that take place after the umbilical cord is clamped at birth include a sudden rise in the systemic vascular resistance, increased pulmonary blood flow, and physiologic closure of the fetal shunts. With extrauterine breathing and expansion of the lungs, tissue oxygenation increases, pulmonary vascular resistance decreases, and pulmonary blood flow increases.
- Pulmonary vascular resistance may increase in the neonate, causing persistent pulmonary hypertension. During transport, give special attention to maintaining normothermia, optimal oxygenation, fluid status, and systemic BP, and minimize acidosis and noise to reduce the risk of the neonate developing severe persistent pulmonary hypertension.
- Patent ductus arteriosus is seen in 50% of extremely premature infants. Minimizing fluid overload during transport can decrease the risk of persistent symptomatic patent ductus arteriosus.
- Nephrogenesis is complete at 36 weeks’ gestation. The glomerular filtration rate at term is low; the creatinine level at birth reflects the mother’s level, but then falls to reflect the infant’s renal function by 1 week of age. Infants tolerate fluid restriction poorly and become dehydrated quickly.
- Total body water represents 85% of body weight in premature infants and 75% of body weight in term infants, compared to 60% of body weight in adults. Contraction of the extracellular compartment and weight loss in the first few days after birth are normal. Fluids should be restricted until after the postnatal weight loss occurs.
- Liberal fluid regimens in the first few days of life have been associated with worse outcomes in premature infants. $D_{10}W$ is typically used for IV fluid maintenance during the newborn’s first

24 hours of life. After 24 hours and the establishment of adequate urine output, 10% dextrose in 0.25% saline is used.

- Neonates are considered to have pressure-passive cerebral circulation. An acceptable mean arterial pressure generally equates to the gestational age of the newborn. It is important to minimize stress and use appropriate sedation for procedures in these patients to minimize BP peaks that can lead to intraventricular hemorrhage.
- Neonates, including premature neonates, show well-developed responses to painful stimuli. Use appropriate analgesic measures to treat neonates for pain.
- Neonates are susceptible to soft-tissue and bony injuries, such as rib fractures, due to incomplete ossification of their bones and fragile tissues. The CCTP should be aware of this vulnerability when administering cardiopulmonary resuscitation.
- Risks for complications in neonates increase as birth weight and gestational age decrease. Complications such as maternal infection, diabetes, premature labor, and the presence of meconium also increase these risks. The CCTP should be familiar with antepartum and intrapartum risk factors.
- The Apgar score is a numeric expression of an infant’s condition after birth. It measures the infant’s appearance, pulse, grimace, activity, and respiration. The score is affected by the infant’s physical maturity, maternal medication intake or narcotic use, and neuromuscular or cardiorespiratory conditions.
- The first steps in stabilizing a neonate with an acute airway obstruction, ineffective respiration, or insufficient cardiovascular circulation are airway management and ventilation. To optimize oxygenation and ventilation, thoroughly suction the neonate’s airway. Continuous positive airway pressure, ventilations, chest compressions, or volume expansion may be necessary. The CCTP should communicate information such as relevant history, vital signs, and physical exam to the accepting facility as soon as possible.

- General assessment of the neonate includes assessment of appearance, work of breathing, or abnormal breath sounds. Evaluation of circulation includes abnormal skin color or bleeding. Determine whether the condition is life threatening.
- The ABCs of neonatal resuscitation are the same as those applied to adults—airway, breathing, and circulation. The most important and effective action in neonatal resuscitation is getting oxygen into the infant’s lungs. Maintenance of normal body temperature is also important.
- As part of the primary assessment, evaluate the airway to determine whether it is patent. Assess cardiovascular and end-organ function. Respiratory problems are a major cause of cardiac arrest in newborns and infants, and prompt recognition and effective management of such issues are fundamental to pediatric life support.
- Familiarity with the length-based, color-coded resuscitation tape allows the CCTP to estimate body weight based on the child’s crown-to-heel length. Most neonatal drug doses are based on body weight, and pediatric supplies are organized according to the color-coded, length-based classification scheme.
- Free-flow oxygen, continuous positive airway pressure, oral airways, bag-mask ventilation, or intubation may be required to assist ventilation in a neonate. The CCTP should be familiar with the equipment and procedures associated with each of these interventions.
- Chest compressions and resuscitation may be necessary if the infant’s heart rate remains less than 60 beats/min despite other interventions. Chest compressions should be performed using the two-thumbs, encircling-hands technique; if this method is not possible, providers may use the two-finger technique.
- Medications are rarely used to resuscitate neonates, but the CCTP should be familiar with the medications that may be administered for this purpose.

- Fluid resuscitation may be required if the infant is hypovolemic. A low umbilical vein is used for this purpose in a newborn; a peripheral IV or intraosseous line is placed in an infant more than a few days old.
- Neonatal transport incubators are typically fitted with a ventilator that provides synchronized intermittent mandatory ventilation. In some areas, high-frequency ventilators are available, as well as the ability to initiate and transport infants on a nitric oxide or extracorporeal membrane oxygenation circuit. CCTPs should be familiar with the technology available in their areas.
- Two types of apnea can occur: primary and secondary. Primary apnea responds to stimulation and supplemental oxygen. Secondary apnea does not respond to stimulation and supplemental oxygen; instead, ventilation is necessary and, if delayed, can lead to further complications.
- If the infant inhales meconium-stained amniotic fluid in utero or at delivery, the airways can become plugged and hypoxia can follow. Meconium aspiration syndrome is the respiratory distress caused by meconium aspiration.
- Tracheal intubation and aspiration with a meconium aspirator are no longer recommended when meconium is present in the amniotic fluid of a depressed newborn at birth. During transport, the CCTP should monitor the infant for complications of meconium aspiration syndrome and be prepared to perform a needle thoracentesis for pneumothorax decompression if necessary.
- Neonates are at increased risk for pneumonia. Premature infants, especially those less than 32 weeks’ gestation, are at high risk for developing respiratory distress syndrome (RDS). Male infants and infants of mothers with diabetes are at increased risk of RDS.
- Providers experienced in the delivery of exogenous surfactant may administer this medication to the infant with RDS in a controlled clinical setting. During transport, following administration of exogenous surfactant, the CCTP needs to monitor the infant for

improved compliance and the potential need to decrease respiratory support.

- In infants with mild RDS, continuous positive airway pressure can be helpful to minimize alveolar collapse during transport.
- A sepsis workup should be performed prior to transport because pneumonia is indistinguishable from RDS in a newborn.
- Simple pneumothorax causes lung collapse; tension pneumothorax is a life-threatening condition. Management of pneumothorax includes transillumination, thoracentesis, and possible intubation. If a symptomatic pneumothorax is suspected, a needle thoracentesis can be lifesaving.
- Critically ill neonates often have a mix of metabolic and respiratory acidosis. Respiratory acidosis often responds to assisted ventilation.
- Cyanosis is caused by decreased arterial oxygenation, which may have either a cardiac or a noncardiac origin. Acrocyanosis is a benign, common condition.
- Cyanotic congenital heart disease (CHD) is caused by developmental anomalies of the heart or major vessels leading to abnormal blood flow. The CCTP may perform tests for CHD ranging from a complete blood count to a hyperoxia test to monitor the infant’s condition and determine the appropriate course of action.
- Sinus tachycardia is a heart rate faster than the norm for the child’s age. Common pathologic causes of tachycardia include tissue hypoxia, hypovolemia, fever, metabolic stress, pain, anxiety, drugs, and anemia.
- Supraventricular tachycardia is an abnormally fast cardiac rhythm. To manage it, emergency interventions such as vagal maneuvers, cardioversion, and pharmacologic interventions should be performed under appropriate supervision.
- Bradycardia in a neonate is usually a result of tissue hypoxia and resolves when tissue oxygenation is restored. After the neonate’s

delivery, cardiac pacing may need to be initiated, but is usually nonurgent care.

- Cardiac arrest is uncommon in children. In this age group, it is typically caused by progression of respiratory distress, respiratory failure, or shock typically associated with hypoxemia and acidosis, rather than by cardiac arrhythmias.
- Persistent pulmonary hypertension (PPHN) is persistence of elevated pressures in pulmonary vasculature after birth. Meconium aspiration is the most common cause of PPHN. Care for an infant with PPHN includes optimizing oxygenation, minimizing stress, maintaining a normal BP, and avoiding or correcting acidosis.
- Shock is a serious condition that can affect all organ systems. If emergent access is necessary to provide fluids in case of shock, an umbilical vein line can be placed in a newborn, or an intraosseous line can be placed in an infant older than 1 week.
- Anemia is defined as a hematocrit value of less than 38% in preterm neonates and less than 42% in term neonates. A neonate with anemia may be asymptomatic or present with signs and symptoms, including tachycardia, jaundice, heart failure, and shock.
- Management of anemia includes managing the ABCs and obtaining IV access (optimally via two sites). Treatment may include volume resuscitation with a normal saline bolus, followed by blood if the infant is in shock, or packed red blood cells and fresh-frozen plasma if coagulopathy is suspected.
- Physiologic jaundice is common in neonates and is due to immature liver conjugation. Jaundice in the first 24 hours after birth reflects a pathogenic process and must be investigated.
- Pathologic jaundice requires investigation, close monitoring, and treatment to prevent irreversible neurologic damage. Laboratory investigations include fractionated bilirubin, blood type, direct antiglobin (Coombs) test, hemoglobin level, and peripheral smear. Other tests may be indicated based on family history, the clinical course, and the results of the physical exam.

- Therapeutic options for hyperbilirubinemia include phototherapy, IV immunoglobulin, and exchange transfusion.
- Any part of the gastrointestinal tract may be affected by congenital anomalies. Bilious vomiting is considered an indication of an obstruction until proven otherwise; passage of meconium does not rule out an obstructed bowel. An obstructed bowel can lead to perforation and peritonitis.
- Gastroschisis is a centrally located, full-thickness abdominal wall defect; it is usually an isolated defect. Omphalocele is a herniation of abdominal contents into the umbilical cord; it is often associated with congenital defects, CHD, and other anomalies.
- If an infant with gastroschisis or omphalocele is born at a remote facility, rapid transport must be provided to a facility with a neonatal intensive care unit and pediatric surgery. Precautions must be taken to cover and protect the exposed abdominal contents and to prevent infection.
- The presence of bile in the neonate's vomit must be treated as a surgical emergency until obstruction, especially malrotation, has been ruled out. The CCTP should know the signs and symptoms of esophageal atresia, proximal intestinal obstruction, distal intestinal obstruction, imperforate anus, and Hirschsprung disease. During transport of neonates with any of these conditions, maintain thermoregulation of the neonate and monitor vital signs closely.
- Obstructed bowel, necrotizing enterocolitis, and iatrogenic perforation can cause perforation of the bowel. Infants with acute intestinal perforation are at high risk of shock and severe metabolic acidosis secondary to inflammation and vascular leak. Hematemesis can occur with several conditions, including volvulus. Intestinal volvulus, which can be fatal, is a surgical emergency.
- Intussusception is the most common cause of intestinal obstruction in children between 3 months and 6 years of age. Intussusception may be reduced by enema, but frequently needs open reduction.

- Diarrhea in a neonate is unusual. In such a case, maintain fluids during transport, monitor vital signs, and maintain normothermia.
- Neonates are susceptible to becoming compromised by serious infectious diseases because their immune systems are not fully developed. The infant’s condition can deteriorate rapidly in such a case. The CCTP must monitor vital signs and maintain normothermia while transferring the patient to a center that can care for a critically ill neonate.
- Hyperthermia is usually caused by overbundling or exposure to excessive heat. It is also seen with herpes simplex infection.
- Hypothermia is more common during the winter months. It can lead to thermal shock, disseminated intravascular coagulopathy, and death in serious cases. Once the patient’s condition is stabilized, place the infant in a prewarmed incubator or cover the infant with warm blankets for transport.
- The most important principle in managing toxic exposure/ingestion is to stabilize the neonate. Be sure to obtain a history from the sending facility. Contact the local Poison Control Center for expert guidance in managing exposure to toxins.
- Most birth traumas are self-limiting and have a favorable outcome. Birth injuries can result from prolonged labor, breech presentation, and extreme prematurity, among other causes.
- Head and neck injuries include vacuum caput and caput succedaneum, which are benign, and serious head injuries such as subgaleal hematoma and cephalohematoma. Nerve injuries often occur because of hyperextension or overstretching during delivery, especially with breech presentation. Recurrent laryngeal nerve injury requires immediate attention and transfer of the neonate to a facility that can provide a high level of care.
- Vaginal breech delivery is the greatest risk factor for spinal cord injury.
- The clavicle is the most common site of fracture seen in newborns. A fractured clavicle will heal itself within 7 to 10 days, as long as the motion of the arm is limited. Pneumothorax is a

rare complication of fractured clavicle. Soft-tissue injuries mostly need routine care.

- Shaken baby syndrome is the most common cause of death in cases of child abuse. Other types of maltreatment include blunt trauma to the abdomen, burns, bruising, and skeletal injuries.
- It is important to be able to distinguish between seizures and jitteriness in the neonate. Seizures are usually a sign of a serious underlying abnormality; jitteriness is characteristically a disorder of the newborn and is rarely seen at a later age.
- Hypoxic ischemic encephalopathy (HIE), caused by oxygen deprivation or decreased perfusion to the brain, is the most common cause of seizures in term and preterm infants. Multiple-organ dysfunction is common after HIE and may affect the outcome for the infant. Hyperthermia has been associated with a worse outcome for the infant with HIE.
- Lethargy is almost always a sign of a serious, frequently life-threatening underlying condition.
- Management of metabolic acidosis includes managing the ABCs; providing adequate oxygenation, ventilation, and hydration; and treating the underlying cause. Treatment may include administering IV dextrose and sodium bicarbonate.
- Hypoglycemia is a medical emergency that can lead to brain damage and even death in severe cases. Signs of hypoglycemia include decreased activity, jitteriness, and seizures.
- Hypocalcemia is most commonly seen in low-birth-weight infants and can occur after significant stress, as well as in infants of mothers with diabetes. Significant hypocalcemia can lead to cardiac arrhythmias, seizures, and tetany.
- An infant with congenital adrenal hyperplasia may present with dehydration and shock. Acute treatment includes normalizing electrolytes and fluid balance, and hydrocortisone replacement after consultation with the supervising physician.
- Transport of a high-risk neonate proceeds through a series of well-organized, established steps. Awareness of local and state

guidelines is important, as is communication among the members of the transport team, the referring facility, and the receiving facility.

- An incubator is a box with clear walls, a heat source, and portal access, in which a neonate can be placed to maintain normothermia and minimize noise stress. An incubator is indicated for transport of infants who weigh less than 10 pounds (5 kg) or are younger than 30 days.
- Communicating with family members regarding what is being done for the infant and a time frame in which they can expect to speak to someone at the receiving facility is helpful in allaying their fears.
- The CCTP must be prepared to manage the challenges presented by different modes of air transport. Airway, circulation, oxygenation, and temperature regulation are foremost among those challenges.

Vital Vocabulary

acrocyanosis A decrease in the amount of oxygen delivered to the extremities. The hands and feet turn blue because of the lack of oxygen.

Apgar score A scoring system for assessing the status of a newborn that assigns a numerical value to five areas of assessment (the total possible score range is 0 to 10).

apnea Respiratory pause greater than or equal to 20 seconds.

atresia Complete absence of a lumen.

caput succedaneum In the newborn, a subcutaneous collection of fluid with poorly defined margins within the scalp, resulting from pressure on the head during delivery.

central cyanosis Blue coloration of the skin caused by the presence of deoxygenated hemoglobin in blood vessels near the skin surface.

cephalohematoma A subperiosteal collection of blood; it may be accompanied by a linear skull fracture.

choanal atresia A congenital narrowing or blockage of the nasal airway by membranous or bony tissue.

congenital adrenal hyperplasia A group of diseases in which the adrenal glands do not function properly and as a result do not produce a sufficient amount of the hormone cortisol.

Coombs test A test used to identify antibodies that may bind to red blood cells and cause hemolysis.

cyanosis Blue discoloration of the gums and face.

cyanotic congenital heart disease (CCHD) Heart disease caused by developmental anomalies of the heart or major vessels (truncus arteriosus, transposition of the great vessels, tetralogy of Fallot, tricuspid atresia, or total anomalous pulmonary venous return) leading to abnormal blood flow. Deoxygenated blood from the right side of the heart is shunted to the left side, causing cyanosis.

diaphragmatic hernia Passage of loops of bowel, with or without other abdominal organs, through the diaphragm muscle; it occurs as the bowel from the abdomen herniates upward through the diaphragm into the chest (thoracic) cavity.

distal intestinal obstruction Partial or complete obstruction of the distal small bowel (ileum) or large intestine.

esophageal atresia A congenital defect, often associated with other anomalies such as tracheoesophageal fistula, in which the esophagus ends in a blind pouch.

gastroschisis A centrally located, full-thickness abdominal wall defect.

gestation Period of time from conception to birth. For humans, the full period is normally 9 months (or 40 weeks).

Hirschsprung disease A congenital lack of ganglion nerve cells in a portion of the distal intestines leading to poor intestinal peristalsis, constipation, and, if not diagnosed and treated, potentially death.

hyperbilirubinemia A condition commonly seen in the newborn, in which an excess of bilirubin develops in the blood; often leads to jaundice.

hypotonia Low or poor (floppy) muscle tone.

hypoxic ischemic encephalopathy (HIE) Damage to cells in the central nervous system (the brain and spinal cord) from inadequate oxygen.

imperforate anus A congenital condition in which the anal opening is either absent or displaced.

inborn error of metabolism A class of genetic diseases mostly caused by defects in single genes that code for enzymes that facilitate conversion of various substances into others; such defects lead to accumulation of substances that are toxic or interfere with normal function.

incubator An enclosed, clear plastic, heated bed that keeps the infant warm.

intussusception An event in which one part of the intestine telescopes into another part of the intestines, leading to a blockage.

jaundice The deposition of bile pigments in the skin; associated with hyperbilirubinemia.

malrotation A congenital anomaly of rotation of the midgut, in which the small bowel is found predominantly on the right side of the abdomen.

meconium A dark green fecal material that accumulates in the fetal intestines and is discharged around the time of birth.

meconium aspiration syndrome The respiratory distress caused by meconium aspiration, which can lead to atelectasis in the lungs, persistent pulmonary hypertension (delayed transition from fetal to neonatal circulation), pneumonitis, and pneumothorax.

necrotizing enterocolitis (NEC) A disorder seen predominantly in premature infants in which the bowel experiences necrosis (tissue death).

neonate An infant during the first 28 days after birth.

neutral thermal environment The temperature at which maintenance of normal body temperature requires only minimal metabolic expenditure.

newborn An infant within the first few hours after birth.

oligohydramnios Decreased volume of amniotic fluid during a pregnancy; a risk factor associated with abnormalities of the urinary tract, postmaturity (birth after a prolonged pregnancy), and intrauterine growth retardation.

omphalocele Herniation of abdominal contents into the base of the umbilical cord.

oxygen hood A tent that is placed over the head of an infant for the purpose of delivering supplemental oxygen.

patent ductus arteriosus A condition in which the ductus arteriosus, which assists in fetal circulation, does not transition as it should after birth to become the ligamentum arteriosum. The result is that the connection between the pulmonary artery and the aorta remains open, allowing some oxygenated blood to move back into the heart rather than all of it moving out of the aorta and into the systemic circulation.

peripheral blood smear A glass slide containing a drop of blood that can be used to microscopically examine the structure of the blood cells.

persistent pulmonary hypertension (PPHN) The persistence of elevated pressures in the pulmonary vasculature after birth, associated with failure to transition from the fetal circulation to the postpartum or normal newborn circulation.

Pierre Robin syndrome A condition present at birth marked by a very small lower jaw (micrognathia) and a cleft palate; the tongue tends to fall back and downward (glossoptosis).

pneumatosis intestinalis Air in the bowel wall as demonstrated by abdominal radiograph.

pneumothorax A collection of gas in the pleural space which causes lung collapse.

polyhydramnios An excessive amount of amniotic fluid that may cause preterm labor.

primary apnea The initial response to asphyxia at birth that responds to stimulation and oxygen therapy; it is characterized by decreased respiratory effort and a slightly decreased heart rate. If not addressed, the infant will progress to secondary apnea.

proximal intestinal obstruction Obstruction at or above the level of the jejunum.

Replogle tube A double-lumen tube used for gastric decompression in infants with gastrointestinal issues. An 8F size is typically used for an infant and is connected to low intermittent wall suction to collect gastric secretions.

sclerema Hardening of the skin associated with reddening and edema.

secondary apnea The response if asphyxia at birth continues, which is characterized by a period of gasping respirations, decreasing heart rate, and decreasing blood pressure; it does not respond to stimulation unless resuscitation is initiated immediately.

seizure A paroxysmal alteration in neurologic function (ie, behavioral and/or autonomic function).

sinus tachycardia A heart rate that is faster than normal for the patient’s age.

sulcus sign A deep lateral costophrenic angle on a chest radiograph, which is associated with pneumothorax.

supraventricular tachycardia (SVT) An abnormally fast rhythm originating above the ventricles.

surfactant A substance formed in the lungs that helps keep the small air sacs or alveoli from collapsing and sticking together; a low level of this substance in a premature infant contributes to respiratory distress syndrome.

term newborn An infant born between 37 and 42 weeks' gestation.

TORCH screen A set of lab values taken to detect congenital infections, including toxoplasma immunoglobulin G and immunoglobulin M (1:1,024), rubella titers, urine cytomegalovirus titer, viral culture (for herpes), and culture of scrapings from any vesicular lesions.

total anomalous pulmonary venous return A condition in which oxygenated blood returns to the right side of the heart, leading to progressive pulmonary edema.

transient tachypnea of the newborn Transient respiratory distress that lasts a few hours in the newborn and occurs secondary to retained fetal lung fluid.

vacuum caput In a newborn, an accumulation of fluid at the site where a vacuum extractor was used to assist in delivering the newborn.

VATER syndrome A syndrome consisting of multiple birth defects: vertebral anomalies, anal atresia, tracheoesophageal fistula and/or esophageal atresia, and renal and radial anomalies.

volvulus Twisting of the stomach or intestine, which often has the effect of cutting off its blood supply.

Wolff-Parkinson-White syndrome A type of heart disease in which ventricular preexcitation produces a delta wave on electrocardiogram. It is one of the conditions that produces supraventricular tachycardia via an accessory pathway.

CHAPTER 24

Pediatric Emergencies

Matthew Harris, MD, FAAP, FAEMS

OBJECTIVES

After completing this chapter, you will be able to:

1. Explain the anatomic and physiologic differences between adult and pediatric patients (p 1294).
2. Explain the physical and psychosocial growth and development of children (pp 1299–1300).
3. Outline the differences in the general approach to critical care transport patient assessment of adult and pediatric patients (p 1300).
4. Discuss the indications, dosage, and route of administration for medication administration in pediatric patients in the critical care transport environment (p 1312).
5. Describe which special pediatric equipment may be needed in a critical care transport (p 1313).
6. Discuss interfacility transport considerations relating to pediatric critical care transport (p 1313).
7. Explain considerations when parents and caregivers accompany pediatric patients during a transport (p 1314).
8. Explain some of the common medical emergencies in the pediatric population, including their assessment and management in the critical care transport environment (pp 1310–1316).
9. Explain common pediatric trauma emergencies, including their assessment and management in the critical care transport environment (pp 1337–1338).
10. Describe the common invasive and noninvasive methods of assisting ventilation in the pediatric patient during transport (pp 1324–1325).
11. Explain critical care transport considerations for a pediatric patient with suspected abuse or neglect (p 1345).
12. Explain critical care transport considerations for a pediatric patient with hypothermia (p 1346).
13. Explain critical care transport considerations for a pediatric patient who has experienced drowning (p 1347).

Introduction

Interfacility transport of the critically ill or injured child can be challenging in many ways for critical care transport professionals (CCTPs). They may have limited clinical exposure to high-risk pediatric patients, with few opportunities to perform advanced procedures for this unique group; moreover, they may feel cognitive distress while caring for these patients. To care for pediatric patients, CCTPs must understand how they differ physiologically, anatomically, and psychosocially from adult patients, and must remain mindful of the important mantra that “Kids aren’t just small adults.” In fact, the unique physiology and anatomy of children make them vulnerable to pathologies that are distinct from those seen in adults, and the CCTP’s ability to recognize sometimes subtle hints of decompensation is paramount in safely treating and transporting these patients.

This chapter addresses some of the special considerations that will enhance the CCTP’s effectiveness in caring for ill or injured children in the critical care transport (CCT) environment. It discusses the special needs of children, the most common reasons for pediatric CCT, and CCT management for pediatric emergencies.

Anatomy and Physiology

Cardiovascular System

Outside the neonatal period, and absent known anomalies, the basic anatomy of the circulatory system in children is the same as that in adults. An important distinction, however, is the recognition that normal vital signs vary by age and condition. Parameters for pediatric vital signs are presented in **TABLE 24-1**.

TABLE 24-1 Normal Pediatric Vital Signs

Age[a]	Respiratory Rate (breaths/min)
Infant	30–53
Toddler	22–37
Preschooler	20–28
School-age child	18–25
Adolescent	12–20
	Responsive Pulse Rate (beats/min)
Infant	100–180
Toddler	96–140
Preschooler	80–120
School-age child	75–118
Adolescent	60–100
	Systolic Blood Pressure Ranges (mm Hg)

Age[a]	Respiratory Rate (breaths/min)
Infant	72–104
Toddler	86–106
Preschooler	89–112
School-age child	97–115
Preadolescent[b]	102–120
Adolescent	110–131

Note: Values for neonates are provided in Chapter 23, *Neonatal Emergencies*.

[a] Age categories may vary across sources and depending on the value being measured. In general, infant is 1 month to 1 year, toddler is 1 to 2 years, preschooler is 3 to 5 years, school-age child is 6 to 12 years, and adolescent is 12 to 18 years.

[b] The preadolescent category is included for blood pressure values. It includes children ages 10 to 12 years, who are normally included in the school-age category.

Data from The American Heart Association. *Pediatric Advanced Life Support.* 2012.

Vital signs must be considered in the context of the clinical setting. A febrile child may have a heart rate and respiratory rate well outside the normal range, but resulting directly from the fever. Anxiety, crying, and pain can also markedly affect vital signs. Important physiologic phenomena in children are their significant physiologic reserves and healthy vascular tone. Children facing physiologic stressors (eg, sepsis, acute blood loss) will maintain a normal cardiac output (determined by the heart rate multiplied by stroke volume) by increasing their heart rate significantly. This means of compensation is supported by a robust catecholamine reserve; once this reserve is exhausted, acute cardiovascular collapse occurs. The clinical implications of this process are important. Adult patients deteriorate in a predictable fashion, with tachycardia, followed by hypotension, and eventually cardiovascular collapse. Children will maintain a normal blood pressure (BP) late into shock, and the presence of hypotension signals imminent and often irreversible decompensation **FIGURE 24-1**.

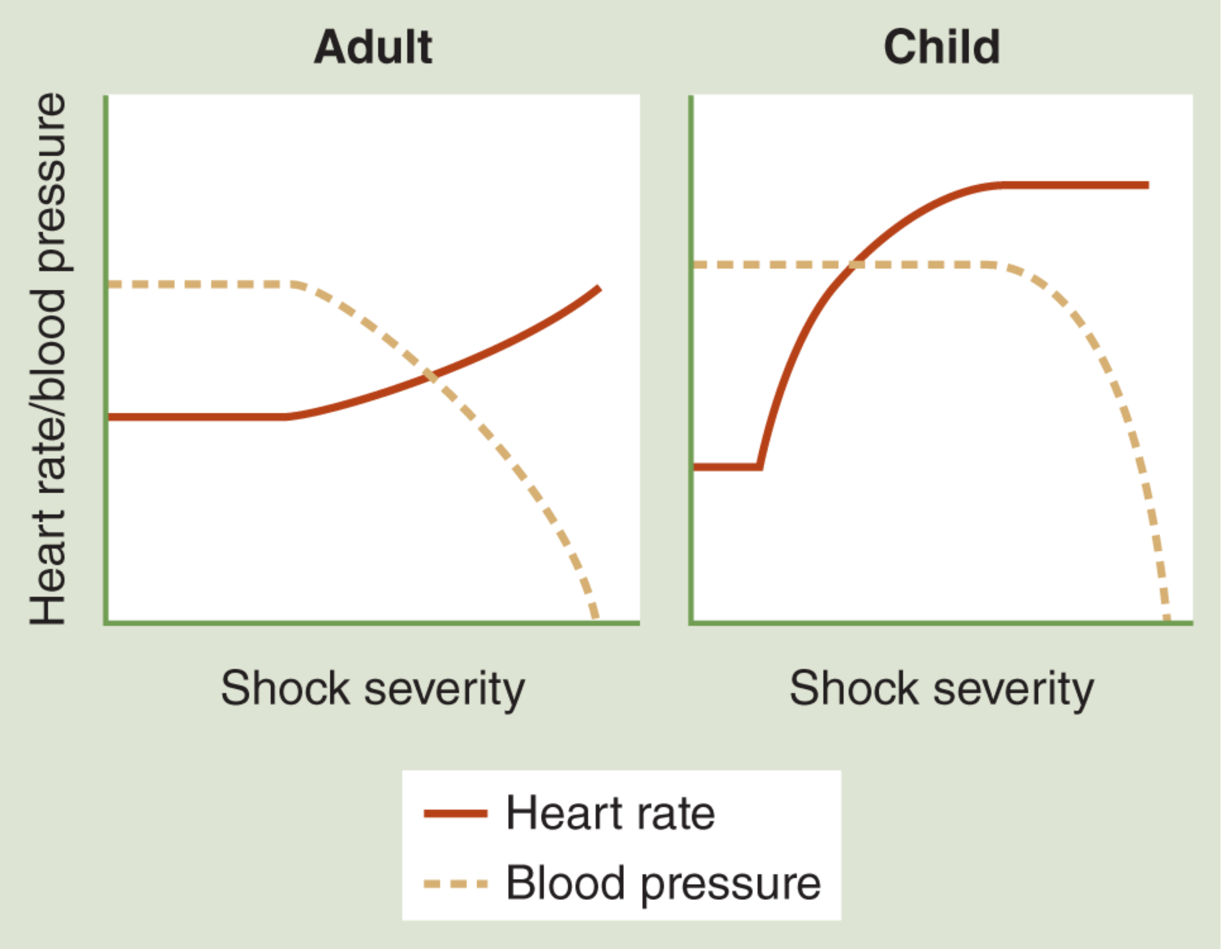

FIGURE 24-1 Blood pressure will not decline in children until they are in the late stages of shock. As cardiac output decreases, vascular resistance increases to maintain the blood pressure. Children do not become hypotensive until they lose a significant percentage of circulating blood volume.

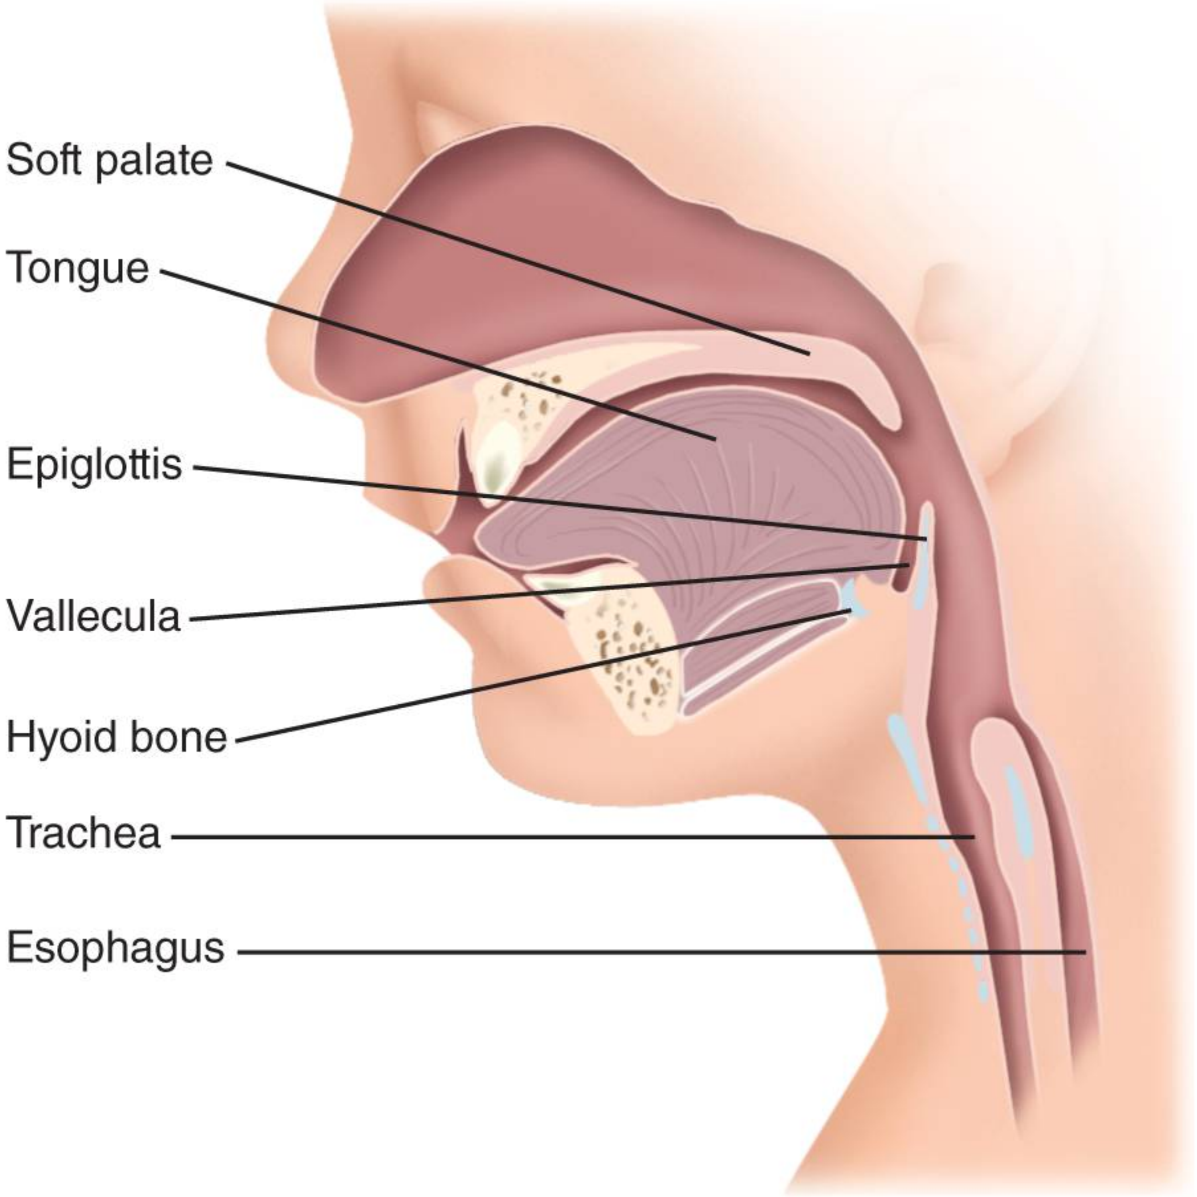
Description

Respiratory System

The respiratory system in children has a number of important physiologic and anatomic differences from an adult's. Central regulation of respirations is immature in infants, which may result in an irregular respiratory pattern, which may or may not be pathologic. Irregular respiratory patterns are especially likely in infants, those born prematurely, and those who sustained perinatal neurologic insults. Children achieve a more regular respiratory rate, depth, and pattern as they approach 1 year of life. Young children are obligate nose breathers, which facilitates breathing while feeding. As such, anatomic abnormalities such as choanal atresia (blockage of the nasal airway by tissue), as well as more benign pathologies such as nasal congestion or rhinorrhea, can lead to significant respiratory distress in young infants.

When assessing a child's airway, the CCTP should consider a number of important anatomic characteristics. As compared to adults, children have a relatively large tongue relative to the size of the oropharyngeal space. In infants and toddlers, the epiglottis is long, floppy, and narrow and tends to extend over the glottis opening more so than in adults **FIGURE 24-2**. The vocal cords are thin and angled, relatively deeper in the larynx, and more anterior than in adult patients. The narrowest part of the young child's airway is the cricoid ring, which provides a degree of anatomic subglottic stenosis. The effects of these airway differences on airway management are discussed later in the chapter.



Soft palate
Tongue
Epiglottis
Vallecula
Hyoid bone
Trachea
Esophagus

FIGURE 24-2 The child's epiglottis and surrounding structures.

© Jones & Bartlett Learning.

The larynx, trachea, and bronchial tree are smaller and less rigid in children than in adults and are therefore more susceptible to obstruction and collapse **FIGURE 24-3**. Smaller airways cause greater resistance to airflow. The airway grows as the child grows, so it is logical that any disease causing narrowing of the airways, such as croup, will be more serious in younger children than in adolescents. The mucosa is less adherent to the airway in younger children and more likely to experience edema, which contributes to increased airway resistance.

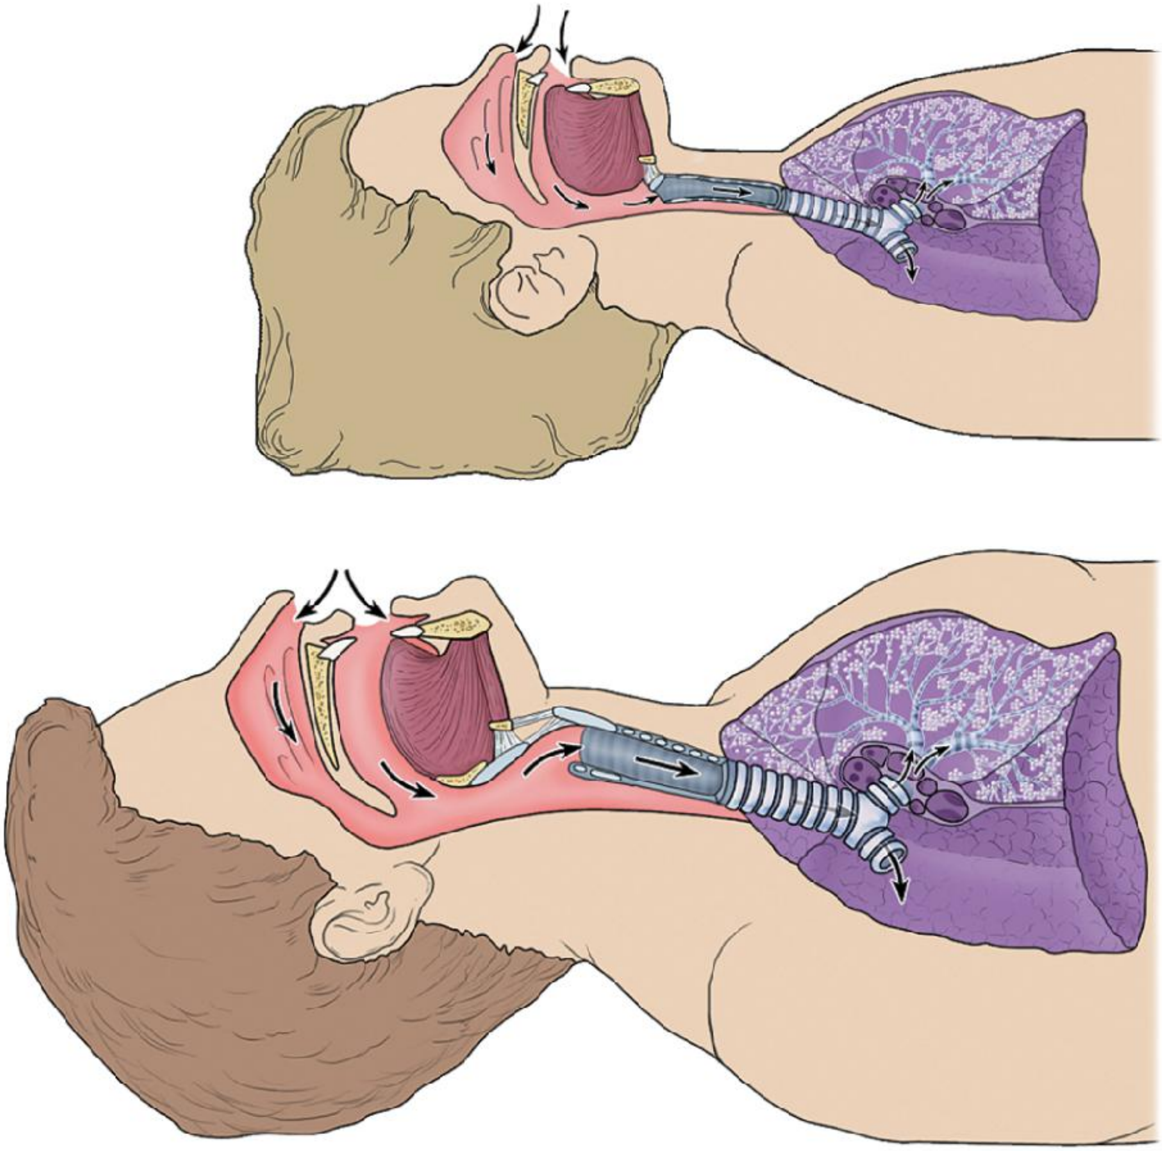


FIGURE 24-3 The anatomy of a child's airway differs in several ways compared with an adult's airway. The tongue is larger and more prominent than in most adult patients. In young children, the glottis is considerably more anterior than in older children or adult patients. There is an anatomic subglottic narrowing in young children, which resolves with growth. The trachea is smaller in diameter and more flexible. The back of the head is larger, and head positioning requires more care.

© Jones & Bartlett Learning.

The airway itself, including the larynx and vocal cords, is lower and narrower in a child than in an adult. The back of the head is larger, and head positioning requires more care. Finally, the mandible is proportionately smaller and the tongue is proportionately larger than in an adult.

At birth, the number of peripheral airways (airways that are less than 2 mm in diameter and consist of small membranous, terminal and respiratory bronchioles, as well as alveolar ducts) is limited. These airways increase in number until about 7 years of age, and they then increase in size through adolescence. Therefore, children up to 3 to 4 years of age are at a relatively higher risk of severe symptoms related to lower airway disease than are older children or adults.

During the first few years of life, alveoli mature from a single cell capillary bed to a double cell bed. The communication between these alveoli, called collateral ventilation, then increases. Because children may not be able to ventilate airways distal to an obstruction, they may be at a higher risk for experiencing **atelectasis** (complete or partial lung collapse).

Finally, infants have highly reactive airways, making them more susceptible to environmental allergens and viral respiratory diseases.

Neurologic System

Key anatomic and physiologic differences in the neurologic system exist between children and adults. The anterior or diamond-shaped fontanelle (sometimes referred to as a “soft spot”) closes at about 18 months of age, and the posterior fontanelle closes by about 2 months of age **FIGURE 24-4**. A normal fontanelle is soft and flat but with a feeling of fullness. These characteristics are important to recognize when assessing children and infants. A sunken or depressed fontanelle may indicate volume loss, most typically from dehydration in this age group. A full fontanelle can be normal in a crying child. However, in an irritable, inconsolable, or ill-appearing infant, a full fontanelle may suggest an infectious process such as meningitis, intracerebral hemorrhage, or obstructive hydrocephalus.

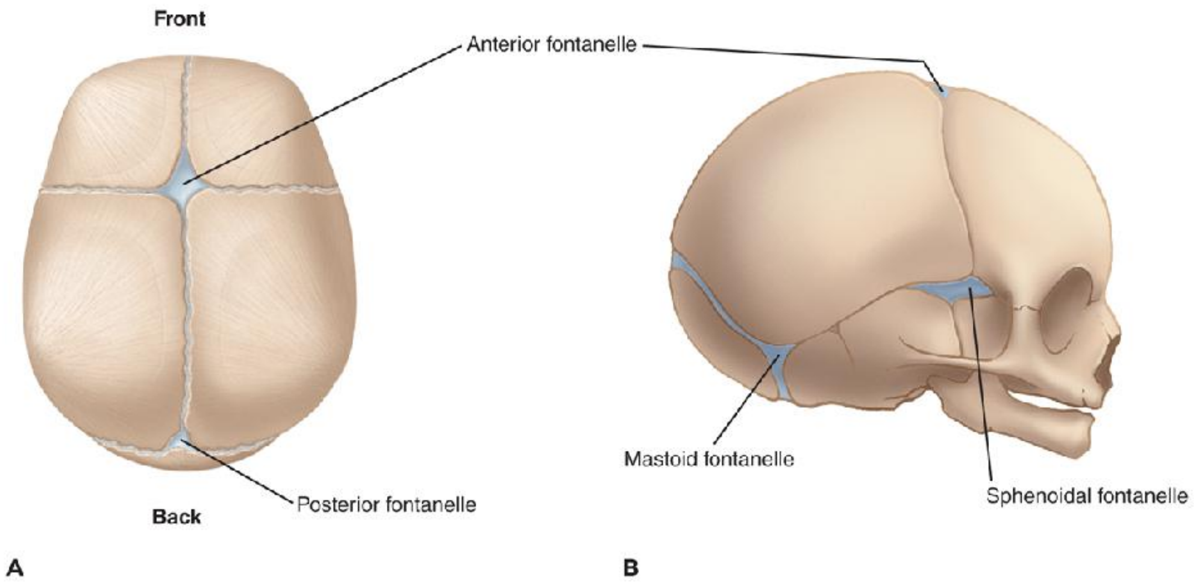

FIGURE 24-4 The fontanelles. **A.** Superior view. **B.** Lateral view.

Description

Children do not have brains that are well compartmentalized, which means their brains have more room to move around within the skull. As a consequence, children are more susceptible to brain injuries, such as diffuse axonal injuries.

CCTPs may encounter children during transfers to a neonatal intensive care unit (NICU). Perinatal birth injuries may be noted during evaluation of the infant's head. For example, a newborn may be born with a **cephalohematoma**, a collection of blood between the bone and subperiosteal space. Although this condition is infrequently seen by the CCTP, it occurs in 1% to 2% of all live births that involve mechanical trauma (forceps or vacuum-assisted delivery). This type of hematoma can occur anywhere on the skull but is found more predominantly in the parietal region of the skull. The hematoma usually resolves in 6 to 8 weeks, and can be associated with linear skull fractures (in 10% to 25% of infants). The CCTP should note the size of the hematoma during the initial assessment and during transport. The swelling does not cross the suture line and may increase in size after birth. Conversely, **caput succedaneum** is merely soft-tissue swelling that usually resolves within 24 hours.

Musculoskeletal System

Several differences exist between the musculoskeletal system of a child and that of an adult. First, children have fewer calcified bones. The immature bones of children are more porous than those of adults and tend to respond to kinetic forces by buckling rather than fracturing. Nevertheless, children do sustain fractures, which often have a morphology distinct from that of the fractures sustained by adult patients. Unique to children, fractures that involve the growth plate (known as Salter-Harris fractures) can affect growth and, when left unmanaged, can result in limb length discrepancies. These epiphyseal–metaphyseal growth plate injuries account for 10% to 15% of fractures in children; however, with reduction and immobilization, most of these injuries have excellent outcomes. Growth plates close in a predictable manner, achieving a mature skeleton in early adolescence.

The ligaments in children are stronger and more resilient to tensile forces, thereby providing strength to the joints. As a result, dislocations are rarely found in pediatric populations compared with adult populations. However, subluxation (partial dislocation) may be seen in infants and toddlers, the classic example being nursemaid’s elbow.

The pediatric spine is characterized by incomplete ossification, epiphyseal growth plates, and hypermobility. As a result, the cervical spine in children is highly flexible, such that young children tend to experience ligamentous injuries more frequently than bone fractures. When fractures occur, they are often avulsion fractures, where a small portion of bone is pulled away from the larger portion of the bone. Compression fractures can be seen with high-impact axial loading injuries. Any vertebral fracture should prompt evaluation for concomitant visceral and spinal cord injuries.

Recognizing Unusual Injuries

Vertebral fractures in the very young should raise suspicion for inflicted injury or underlying bone disorders.

Children have relatively large, heavy heads with weak neck muscles, causing the head to lean forward when they fall. As a consequence, pediatric patients are more susceptible to head injuries. Rapid deceleration injuries resulting in hyperflexion and torsion forces are most commonly seen in children.

The child’s thorax is pliable, meaning it can withstand greater kinetic forces without fracturing. The chest is surprisingly resilient and can absorb a significant amount of energy compared to the child’s size. Rib fractures are uncommon, and should prompt evaluation for internal injuries, especially in small children, where rib fractures are suggestive of child abuse. The pediatric pelvis is more flexible than that of adult patients. Hip laxity in the neonatal period can result in dislocation or subluxation.

Gastrointestinal System

The cardiac sphincter, which is the valve between the esophagus and the stomach, is located above the diaphragm until 6 months of age and does not completely close, which increases the risk for regurgitation. The relatively small stomach capacity combined with poor satiation may potentially result in overfeeding, which further increases the risk of reflux. Children with reflux are at risk of aspiration, though aspiration is less common in term infants and those without neurologic insult. Reflux can present with vomiting, fussiness, and irritability. Sandifer syndrome—that is, arching of the back seen with severe reflux—is often mistaken for a seizure condition.

Because young children eat frequently, the CCTP should obtain a history of recent oral intake. This information can help the CCTP prepare for vomiting that can result from positive-pressure ventilation or endotracheal (ET) intubation.

Liver function is also immature in young children, resulting in fewer glucose stores. As a result, these patients are susceptible to hypoglycemia during periods of poor oral intake or high gastrointestinal or renal losses. Therefore, an essential component of pediatric resuscitation is checking blood glucose levels.

Another key difference between adults and children is that the abdominal muscles are weaker in the younger child, providing less protection to the internal organs. The liver and spleen extend below the costal margin, which renders these organs more susceptible to blunt abdominal trauma.

Renal System

The pediatric renal system has some significant physiologic differences from the adult renal system. Notably, children have a higher percentage of body water compared to adults, making them more susceptible to dehydration. In addition, children are unable to concentrate urine as effectively as adults. They may be more susceptible to electrolyte loss because they have higher clearance rates of blood urea nitrogen (BUN), creatinine, and electrolytes. The minimum urine outputs expected in pediatric patients are as follows:

- Infant: 2 mL/kg/h
- Child: 1 mL/kg/h
- Adult: 0.5 mL/kg/h

Infants younger than 6 months cannot tolerate free water (devoid of electrolytes). Ingesting large volumes of free water in this age group, which can occur when parents dilute baby formula with the aim of making the volume last longer, can lead to life-threatening hyponatremic seizures. Urine output is an important measure of hydration status. A key component of the patient history is the number of wet diapers in the past 12 to 24 hours. Many infants urinate with each feeding and will produce 10 to 12 diapers per day. Parents often have a good sense of their child’s normal urine output.

Thermoregulation

Temperature regulation in infants is not fully developed, making them highly susceptible to hypothermia. Infants have thinner skin and lack a subcutaneous layer of fat. They are unable to shiver and lose heat through the head, which is proportionally larger relative to the body. Low body temperature has numerous manifestations in young children and may be a harbinger of sepsis or hypotension. Young infants' skin may appear mottled and will feel cool to the touch.

Children have a high ratio of body surface area to mass relative to the ratio for adults. This ratio can be advantageous to children when they are exposed to mildly warm environments and during times of intense exercise in mildly cool weather, because they have an increased ability to dissipate heat. However, when this population is exposed to temperature extremes of cold and heat, their ability to dissipate heat can be a disadvantage that leads to environmental emergencies.

Metabolism

The basal metabolic rate is accelerated in the pediatric population, which means children consume glucose and oxygen at a higher rate than adults do. An infant's consumption of oxygen is, in fact, twice that of an adult. In combination with an infant's poor respiratory reserves, this relatively high oxygen demand can lead to earlier hypoxia in response to a respiratory insult. Like the rate of metabolism, the rate of onset of hypercapnia and hypoxemia, with **bradypnea**, is accelerated in this patient population, warranting close monitoring during transport.

While an epidemic of obesity has been noted in the pediatric population in the United States, children generally have less adipose tissue than adults. Because many emergent medications are lipophilic (eg, propofol), and because children have a higher basal metabolic rate than adults, redosing may be required in the pediatric population.

Glucose Requirements

Infants and small children have decreased glycogen reserves and an immature liver that is not capable of stimulating glycogen release when required due to metabolic stressors. When ill or injured, many children refuse to eat and drink. This refusal, coupled with the additional stress on the body from the illness or injury, can increase the risk for hypoglycemic events. The need to assess and reassess glucose levels is paramount while caring for the critical pediatric patient during a transport.

Pediatric patients with hypoglycemia present with a broad spectrum of symptoms. Newborns and young infants may be asymptomatic or may have nonspecific symptoms ranging from irritability to lethargy, pallor to cyanosis, and tremors to seizures. By comparison, older children will have a more classic presentation that mirrors adult symptoms (anxiety, diaphoresis, tachypnea, and weakness).

The treatment regimen for hypoglycemia varies depending on the patient's weight, age, and clinical status. While it is preferable to resolve hypoglycemia with enteral nutrition, critically ill or injured children should be kept on NPO (*nil per os*, Latin for "nothing by mouth") status during CCT. Children require 0.5 to 1 mg/kg/dose of dextrose when hypoglycemic. When translating this into a milliliter per kilogram dose of dextrose solution, the "rule of 50" is useful. Using this rule, the volume to be administered multiplied by the dextrose content equals 50 (Volume × Dextrose content = 50). For example, volume would be calculated as follows for a patient receiving 10% dextrose (D_{10}):

$$\text{Volume} \times 10 = 50$$

$$\text{Volume} = 50/10$$

$$\text{Volume} = 5\text{ mL/kg}$$

Thus, a patient receiving D_5 solution would require a 10-mL/kg bolus, and a patient receiving D_{25} is typically administered a 2-mL/kg bolus. Due to the risk of extravasation, D_{50} is typically avoided in children and adults. If the hypoglycemic episode has been corrected prior to the arrival of the CCTP, then a glucose maintenance infusion should be initiated at a rate of 6 to 8 mg/kg/min or per the standing protocol.

Growth and Development

The CCTP will encounter children at various stages of physical and psychosocial development. In some of these patients, the cognitive ability to recognize and cope with the stressor of acute illness or injury will be limited. Having a foundational understanding of developmental stages can enable the CCTP to engage with the child at an appropriate level. Where young infants are incapable of verbalizing their distress, their crying pattern or their responsiveness to their caregivers can provide a great deal of information about their status. In contrast, older children and adolescents may be acutely aware of the seriousness of their ailment and may respond emotionally, such as with anxiety, fear, or anger.

Additionally, CCTPs must be attuned to the needs of these patients' parents. They are also under enormous stress. The intimate moments during transport are an opportunity to bridge the divide that many parents feel with members of the caregiving team who may be only transiently involved in their child's care.

Physical Growth and Development

One extremely important aspect of pediatric care is an understanding of normal growth and development. Failure to meet normal developmental milestones, such as the ability to walk or talk, may be a sign of an underlying illness, a family crisis, or a neurologic injury (ie, a lack of oxygen or blood flow to the brain that may permanently affect the child's ability to reach normal developmental milestones) **TABLE 24-2**. Knowledge of the child's developmental level also helps to guide safety considerations.

TABLE 24-2 **Developmental Milestones**

Age (months)	Milestone
2	Smiling
5	Rolling over
9	Crawling
10	Grasping small objects
12	Walking
24	Talking

© Jones & Bartlett Learning.

Ideally, the CCTP should have an understanding of the child's developmental level prior to assessment so that appropriate comparisons can be made. Parents and other caregivers are the best source for information about how the child will react under normal circumstances. The parent or primary caregiver may be able to tell you the developmental age of the child, which will guide the manner in which you communicate with the child and explain procedures. Communication techniques for children who do not have language skills include using sign language, observing facial expressions, and having the child move their eyes to the right or left or blink a specific number of times to indicate yes or no. Remember that parents are likely their child's best advocate and can be a tremendous resource in helping guide the child through the stressors of the CCT process.

Psychosocial Growth and Development

Psychosocial concerns for pediatric patients vary tremendously based on the patient's age:

- An infant's primary fear is often separation from the parents, so efforts should be made to minimize the time of separation.

- Toddlers also fear separation from parents or caregivers, and they fear loss of control. Distracting tools such as toys or electronic devices (eg, a parent’s phone) can help alleviate a toddler’s stress and allow the CCTP to complete the exam and interventions.
- Preschoolers also fear loss of control, in addition to bodily injury, the dark, and the unknown. Explain your actions clearly and provide plenty of reassurance.
- Like preschoolers, school-age children fear body injury, so simple and concise explanations should be used to describe procedures as ways to help the child.
- Adolescents and teenagers may fear a loss of control or an alteration to their physical appearance. Encourage the adolescent’s involvement and respect the adolescent’s privacy. Adolescents often demonstrate increased compliance if honest explanations are given and if they are allowed to participate in decision making regarding their health care.

Basic care strategies to address psychosocial concerns span all age groups. Foster trust by addressing the child at eye level, using their first name, and explaining medical procedures using age-appropriate words. Honesty is important, especially regarding painful procedures such as a needlestick. Preschoolers and school-age children fear the unknown. If a procedure will be uncomfortable, prepare the parents and child for this reality, and offer an age-appropriate explanation of how you will attempt to mitigate that discomfort. Encourage a sense of control by offering choices whenever possible, while keeping in mind that bargaining and negotiating may not be possible or appropriate in some situations. At all times, maintaining a calm and confident demeanor can help reassure both the parent and the child.

Approach to Parents and Caregivers

CCTPs should do a self-assessment to ensure they are prepared—academically, technically, and emotionally—to care for pediatric patients. Children of any age may be seriously ill or injured. CCTPs may become distracted by the emotional response of a child or parent. Be mindful of your own emotions, and watch for signs of increased stress in your CCT partners.

Be sensitive to the fact that the child may not be the only person on scene who will benefit from compassionate care; you should also consider the needs of the parents, guardians, or caregivers. Their responses may include guilt for not preventing or recognizing the illness or injury, frustration related to not being the primary caregiver to the child during hospitalization (loss of parenting role), or helplessness from a perceived inability to protect the child. Parents or other caregivers often feel fearful, out of control, and uninformed, so make an effort to keep them informed and actively involved in health care decisions. This often requires that information be repeated, sometimes on numerous occasions. Whenever possible, provide parents or caregivers with written information and involve them in the plan of care.

Pediatric Assessment

Patient assessment for pediatric patients follows the same basic process as for other patients, as described in Chapter 5, *Patient Assessment*. This process begins on receipt of the referral call. CCTPs should collaborate with their call-intake center to identify the crucial clinical information needed to facilitate interfacility transport, without prolonging time from call receipt to arrival at the patient's bedside.

Your primary survey will include an assessment of the patient's airway, breathing, and circulation, using both your clinical evaluation and the available monitoring technology (eg, pulse oximetry, external or invasive cardiorespiratory monitoring). Any abnormal finding indicates a need for immediate treatment and may require deferral of the next step; for example, if the airway is not patent as the result of an airway obstruction, intervention must be immediate.

Obtaining the patient's weight, age, and vital signs can help you evaluate the patient's acuity and form your care plan. Staff at the receiving facility will determine whether a child is weighed during triage or on arrival to the treatment area. At the facility, the actual (not estimated) weight is measured and reported in kilograms. Estimating a weight or reporting it in pounds can result in drug dosing errors. In the CCT setting, you should obtain the child's weight from the parents or caregivers and use a computerized program or printout to identify resuscitation medications, doses, and equipment used in the child's care. In the prehospital setting, providers may use a tool, such as a length-based resuscitation tape, for estimating the child's weight and selecting appropriate medication doses **FIGURE 24-5**.

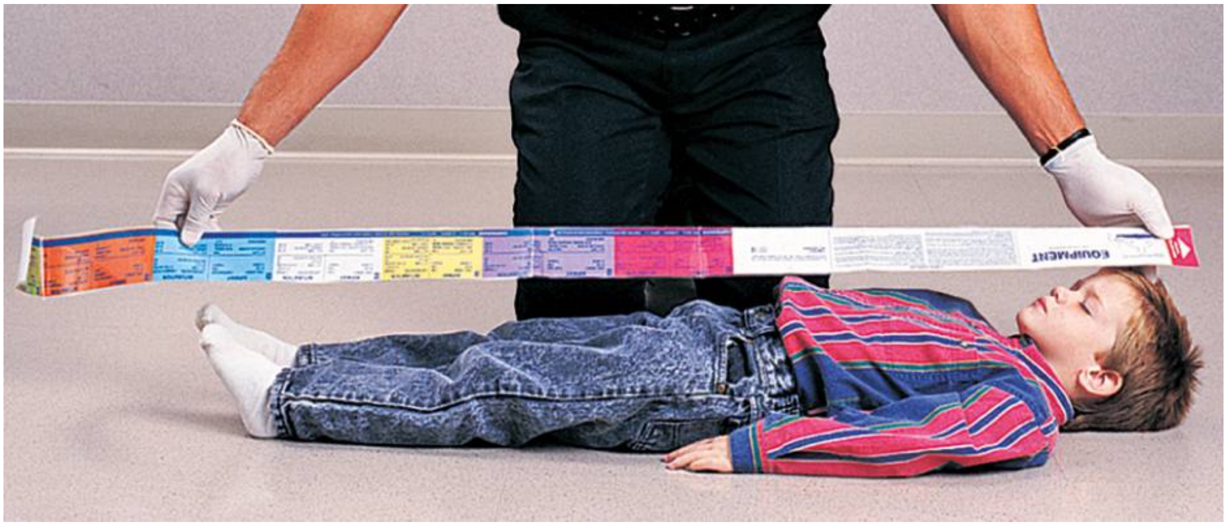

FIGURE 24-5 Using a length-based resuscitation tape helps providers estimate a child's weight and identify the correct size for pediatric equipment and medication doses when an exact weight is not available. Such equipment, due to its limited precision, is not an acceptable tool outside of emergency resuscitation settings.

© Jones & Bartlett Learning.

All pediatric assessments should begin with a general impression that can be accomplished using the **pediatric assessment triangle (PAT)** **FIGURE 24-6**. The PAT is an assessment tool based on the child's appearance, work of breathing, and circulation. Appearance can be assessed using the **TICLS** (tickles) mnemonic: Tone, Interactiveness, Consolability, Look or gaze, and Speech or cry **TABLE 24-3**. The nature of the child's airway sounds and signs of increased breathing effort characterize the work of breathing. Circulation is assessed by observing the child for pallor, mottling, or cyanosis. By combining the three parameters of the PAT, the CCTP can form a general impression of the child's stability and, in conjunction with the chief complaint, can make decisions regarding the need for acute interventions.

TABLE 24-3 **Characteristics of Appearance: The TICLS Mnemonic**

Characteristic	Features

Characteristic	Features
Tone	Is the child moving or resisting examination vigorously? Does the child have good muscle tone? Is the child limp, listless, or flaccid?
Interactiveness	How alert is the child? How readily does a person, object, or sound distract the child or draw the child's attention? Will the child reach for, grasp, and play with a toy or exam instrument, such as a penlight or tongue blade? Is the child uninterested in playing or interacting with the caregiver or CCTP?
Consolability	Can the child be consoled or comforted by the caregiver or the CCTP? Is the child's crying or agitation relieved by gentle reassurance?
Look or gaze	Does the child fix their gaze on a face, or does the child have a blank, glassy-eyed stare?
Speech or cry	Is the child's cry strong and spontaneous or weak and high pitched? Is the content of speech age appropriate or confused or garbled?

© Jones & Bartlett Learning.

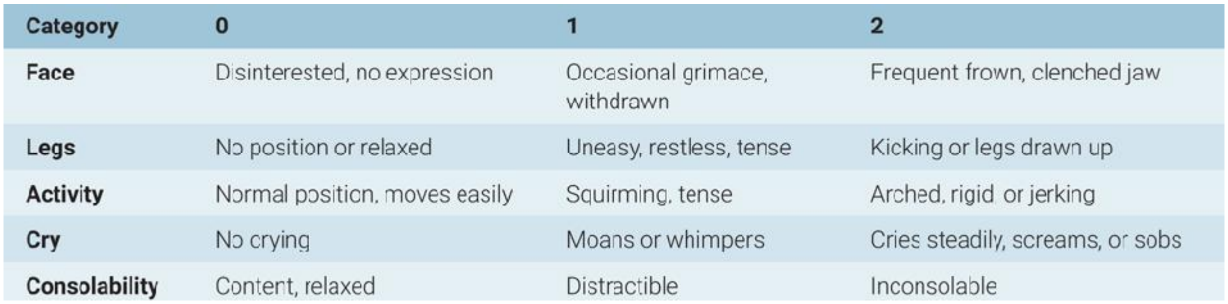
After using the PAT to form a general impression of the patient, perform a primary assessment by evaluating the following items, in this order:

- Airway patency
- Respiratory rate and quality
- Pulse rate and quality
- Skin temperature and capillary refill time
- BP (using age-appropriate equipment)
- Neurologic status

The child's neurologic status can be obtained by forming a general impression and assessing the level of consciousness (LOC) and pupillary reaction. In young infants, an assessment of the patient's suck reflex and axial tone (where appropriate) can often indicate the severity of the child's illness: A poor suck or a decrease in axial tone suggests serious pathology. The neurologic status in older children can be assessed by their ability to interact with the parents or caregivers in an age-appropriate way. Older children should be able to follow commands and answer questions.

All pediatric patients—even the youngest children—should be assessed for pain. The quality of pain can be assessed using a numeric scale for older children and adolescents. Younger children and infants may be assessed using pain scores, such as the **FLACC scale** **TABLE 24-4** or the FACES scale **FIGURE 24-7**. Each of the five categories that make up the FLACC scale—face, legs, activity, cry, and consolability—is scored from 0 to 2, which results in a total score of 0 to 10. The pain assessment should be a dynamic component of any interfacility transport: Assess, intervene, and reassess. The pediatric patient's pain level can be more difficult to determine, and analgesia should be carefully, but adequately, dosed. For children who are intubated and sedated, a number of validated tools can be used to assess the depth and appropriateness of sedation.

TABLE 24-4 FLACC Scale



Category	0	1	2
Face	Disinterested, no expression	Occasional grimace, withdrawn	Frequent frown, clenched jaw
Legs	No position or relaxed	Uneasy, restless, tense	Kicking or legs drawn up
Activity	Normal position, moves easily	Squirming, tense	Arched, rigid or jerking
Cry	No crying	Moans or whimpers	Cries steadily, screams, or sobs
Consolability	Content, relaxed	Distractible	Inconsolable

Scores add up and range from 0 to 10.

Description

Although physiologic abnormalities are more likely to be identified by applying the PAT and performing the primary assessment, the secondary assessment may further identify anatomic or physiologic abnormalities. Sometimes it is not possible to perform this exam prior to the transport because the patient is unstable and needs to be transported immediately. In such a case, the secondary assessment should be conducted en route to the receiving facility. The secondary exam should consist of a detailed head-to-toe exam, with a special focus on the body region or system known to be involved in the underlying pathology, but also with the express purpose of identifying other issues that may need to be addressed. Detection of additional injuries is especially important in the trauma setting.

History

As mentioned previously, the history begins with the initial referral call. While a great deal about the history of the present illness will be obtained during the report from the referring hospital staff, obtaining a baseline history before departure can help the CCT team prepare to care for the child. Once the team is at the bedside, parents or caregivers can provide extensive information regarding the child's history. The history for infants will include the perinatal history, delivery information, gestational age, and gestational weight. A history from the parents is crucial in all pediatric transports, but is especially helpful for chronically ill or technology-dependent children. Many of these children have abnormal vital signs and physical exam findings at baseline; a thorough report from the primary caregiver can help the CCTP to understand the child's acute issue in the context of the underlying medical issues.

Scene or situation information may be useful as well, especially for children with traumatic injuries after a motor vehicle accident where the mechanisms of injury or extent of damage may help providers plan for the child's needs. Scene information is also valuable if there is any concern for nonaccidental trauma or neglect. CCTPs may be able to obtain this type of information from prehospital run sheets or through direct conversation with the responding EMS providers. Information from these sources may include a description of the environment and details about the accident scene, among other important pieces of information. For example, if providers responded to the child's home, they may note that the home was inadequately heated, weapons were visible and within the child's reach, or trash had accumulated on the floor and furniture. If providers responded to a vehicle crash, they may note that the child was buckled into the front passenger seat rather than being properly secured in a car seat in the backseat.

Special Populations

Children with special needs represent a particularly vulnerable group within the pediatric population. Parents and caregivers of these children know their needs well and can contribute significantly to both the history of the present illness and the broader clinical picture. They can describe the child's medications, baseline function, and degree of technology dependence. For example, children with complex congenital heart disease often live in a hypoxic state. It is crucial that the CCTPs obtain this information, as providing too much oxygen to children with complex congenital heart disease can worsen the clinical picture. For children with severe developmental delays, or those who exist on the severe portion of the autism spectrum, parents can describe the child's functional status and suggest ways to support the child during interfacility transport.

Pediatric Medication Delivery

Safely delivering medications to critically ill or injured children is challenging. Nearly all emergent medications are administered as weight-specific doses, and some have age restrictions. There are a number of latent safety issues (ie, flaws in organizational design or culture that contribute to medication errors) related to drug dosing for pediatric patients. Examples include medications prepackaged in adult doses, the need to dilute medications, the need to use pediatric-specific dosing calculations, the use of Buretrol fluid volume limiters, and the need for pediatric- or neonate-specific syringe pumps. Identification of pediatric medication doses often requires the CCTP to perform calculations, which increases the risk of errors. Doses of high-alert medications, such as opioids, heparin, insulin, and potassium chloride, require an independent recheck before they are administered.

Several methods are available for delivery of medications to pediatric patients, including intravenous (IV) push, syringe pump, or infusion pump. Because infusion pumps include safety guards, such as a flow stop, they are routinely used for the administration of fluids and medications. When using a syringe or infusion pump, always follow the manufacturer’s recommendations for flushing and maintenance. The best option for administering resuscitation medications is a vascular access device.

A pediatric resource with a formulary may be helpful in determining the amount and type of diluent required for specific medications. The formulary will also list the time frame for administration. Medications used in pediatric CCT are described in Chapter 8, *Critical Care Pharmacology*.

Most children are kept NPO during CCT. It is important to identify any oral medications that the child may be due to receive during transport, as IV alternatives are often available and can be substituted if necessary; for example, oral levetiracetam has an IV equivalent. If children lose vascular access en route, it is important to consider other methods of administration, as obtaining access during transport can be technically challenging. Many opioids and benzodiazepines, as well as naloxone, glucagon, and ketamine, among other drugs, can be administered via the intranasal route (with use of a mucosal atomizer device). This route is well tolerated, with good absorption, and avoids the pain associated with needlesticks en route. Intramuscular and subcutaneous routes can also be used.

CONTROVERSIES

Pediatric medication errors are a major focus of concern in hospitals. Measuring devices used to calculate emergency drug doses have contributed to errors for hospitalized children. Although use of such measuring devices for estimation is appropriate for initial prehospital and emergency department (ED) encounters, an accurate height and weight must be obtained on hospital admission and used to prepare an individualized dosing list of emergency medications for each child. CCTPs should consider printing a patient-specific medication-dosing document before beginning transport. Using this reference reduces the cognitive stress of performing emergent medical calculations en route. Any medication errors should be reported for evaluation as part of a robust continuous quality improvement initiative for pediatric prehospital medication administration.

Airway

All infants are obligatory nose breathers, meaning they actively breathe through their mouths only if they are crying. Therefore, nasal congestion in an infant can produce significant respiratory distress. Irrigation with normal saline spray and suction with a bulb syringe are often the only interventions necessary to clear the nasal airways. Positioning the infant with the head up at a 30° to 45° angle also aids in keeping the nasal airways clear. Administration of oxygen via a nasal cannula may work well in infants with mild to moderate respiratory distress because a significant amount of tidal volume comes through their noses and they do not tolerate face masks **FIGURE 24-8**.

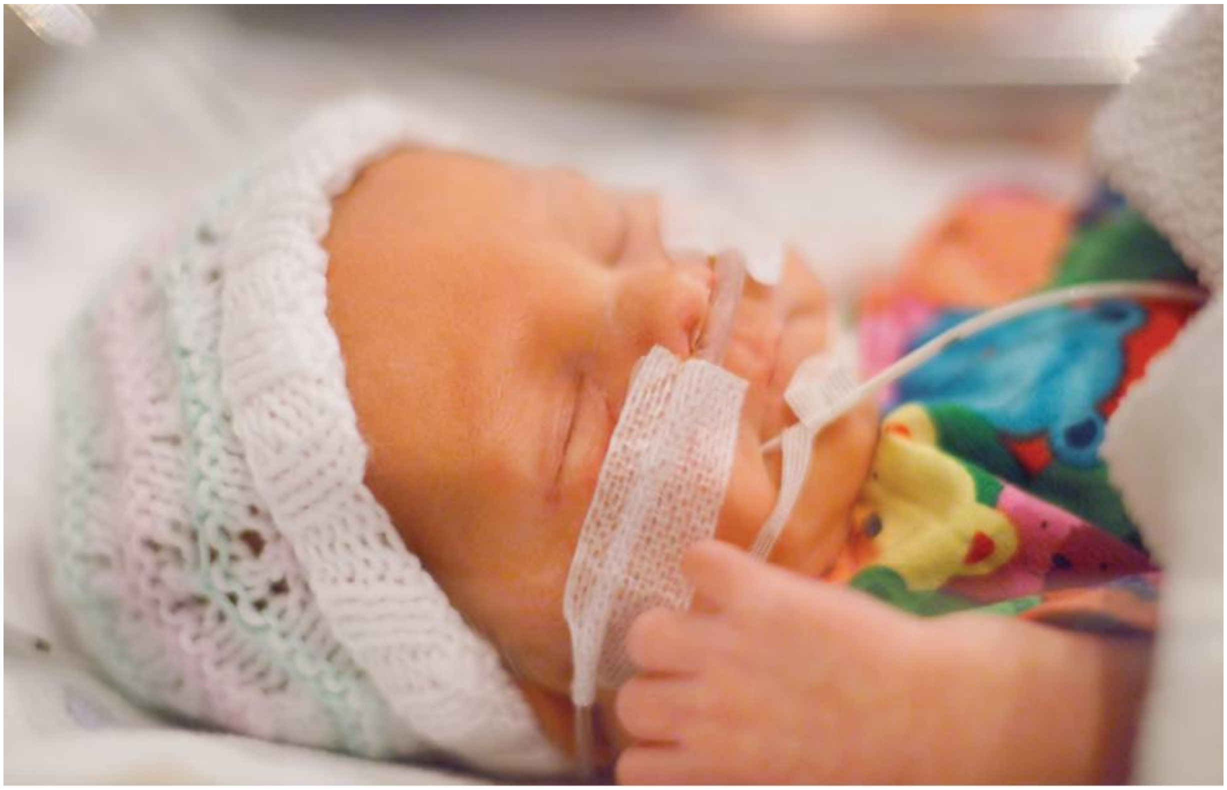

FIGURE 24-8 A nasal cannula may be the most effective way to provide oxygen to an infant in respiratory distress.

© Steve Lovegrove/Shutterstock.

Anatomic considerations are important when planning airway management. As mentioned earlier, children have relatively large tongues in relation to the size of their mouths. Proper choice of blade size, proper positioning, and effective sweeping of the tongue are essential for successful intubation. It is also common to find large tonsils and copious oral secretions in pediatric patients. In most cases, spending the time to properly prepare the child will make securing the airway faster and easier. This approach prevents the tube from getting caught on the angled vocal cords, which are relatively more anterior compared to those of adults. In young children, cartilaginous support for the trachea varies, requiring that providers be especially careful not to compress the pediatric upper airway. Further, providers must avoid hyperextending the neck.

Placing the noninjured child in the sniffing position with the aid of a rolled towel provides optimal positioning **FIGURE 24-9**.

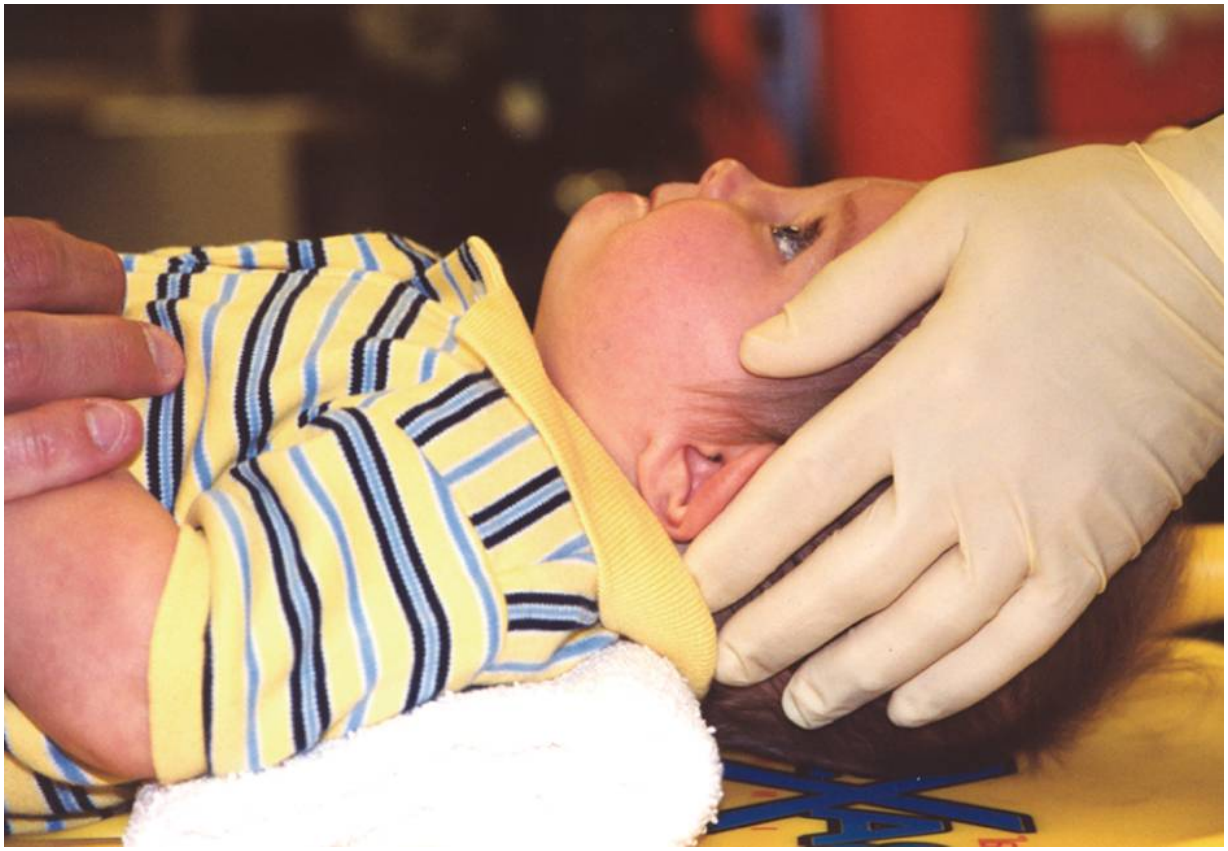

FIGURE 24-9 For an infant who has not sustained traumatic injury, a rolled towel beneath the shoulders helps to maintain the airway in a neutral position.

© American Academy of Orthopaedic Surgeons.

Patency of the pediatric airway may be compromised for numerous reasons, including congenital anomaly, infections, trauma, edema, foreign body airway obstruction, or loss of airway protective reflexes. Foreign body airway obstruction is a particularly high risk in children younger than 5 years. Diminished protective reflexes may result from any condition that causes a decreased LOC, including infection, trauma, neuromuscular disorder, and toxic ingestion.

Clinical signs of upper airway obstruction are those typical of respiratory distress, including tachypnea, nasal flaring, abnormal respiratory sounds, and the use of accessory muscles (retracting).

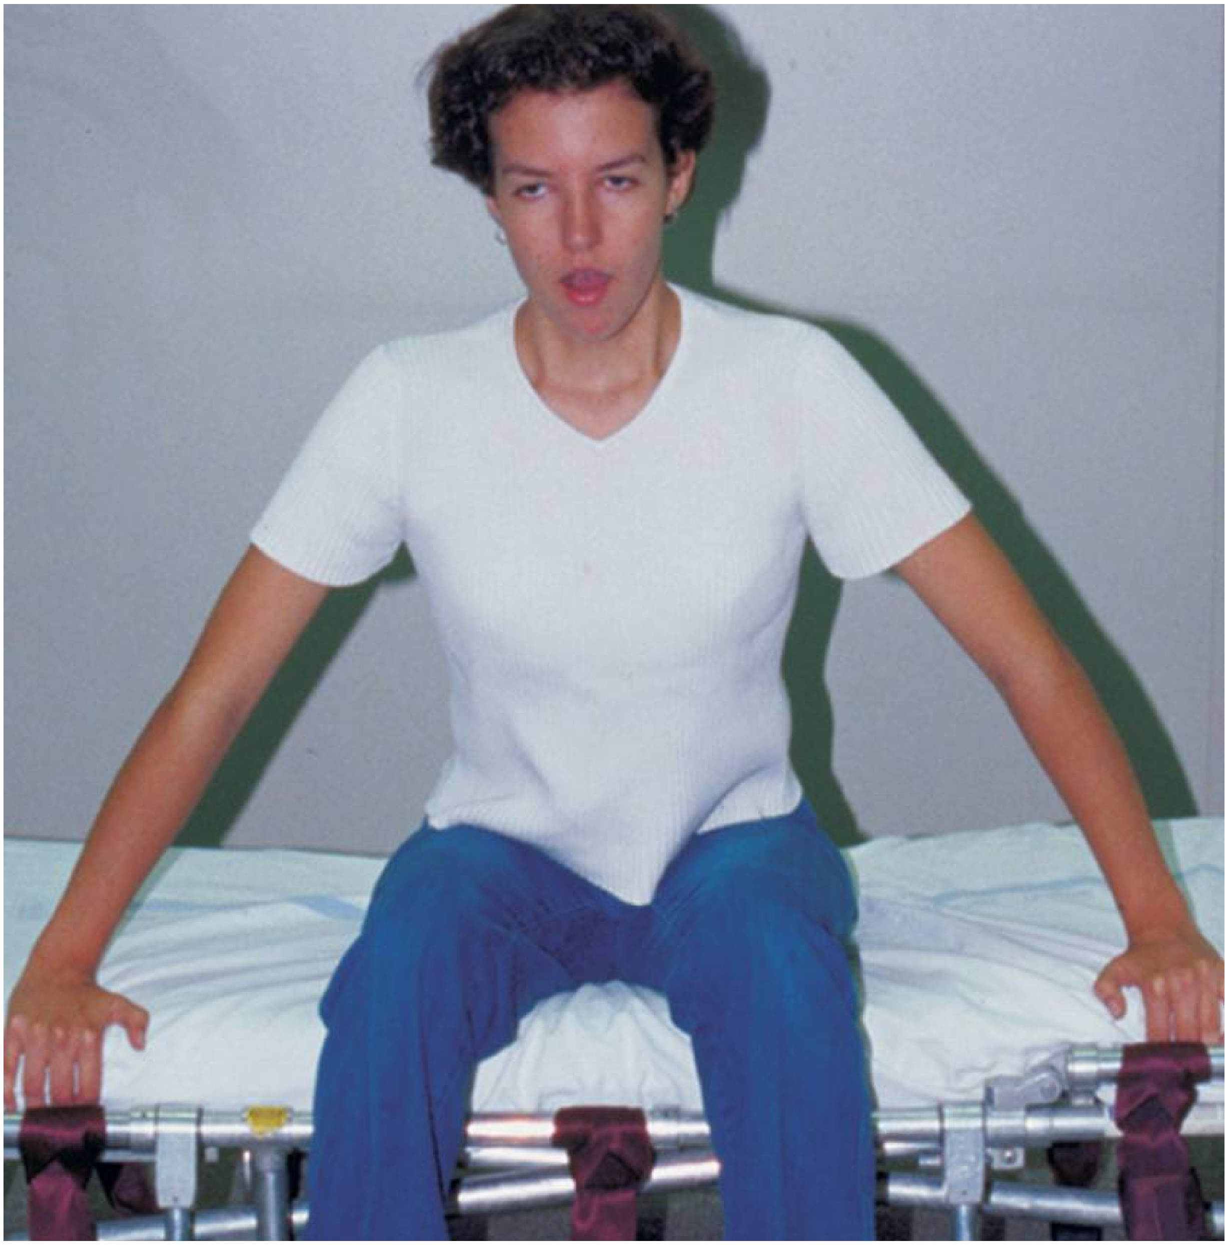
Symptoms more specific for upper airway obstruction include stridor (a high-pitched, primarily inspiratory sound), snoring, poor control of secretions, and biphasic wheezing. Certain infectious upper airway etiologies, such as a peritonsillar abscess, can also present clinically as drooling, difficulty speaking, and trismus (difficulty opening the mouth).

A child with a decreasing LOC may not be able to protect their airway and may require airway management. The loss of protective reflexes occurs in ascending order: The swallowing reflex is lost first, then coughing, then the gag reflex, and finally the corneal reflex. A useful intubation suggestion is to assess the corneal reflex prior to inserting an oral airway or to assess for paralysis related to neuromuscular blocking agents. A child who does not blink when the open eyelids are stroked no longer has a gag reflex. This strategy avoids the need to test the gag reflex with a tongue blade or a suction catheter, which may cause the child to vomit and thus aspirate.

Breathing

Children with difficulty breathing present with a variety of clinical symptoms, depending in part on the child's age and the disease pathology. During the assessment of breathing, the CCT should assess for the rate and quality of breathing. Early signs of distress may include **tachypnea** and use of accessory muscles. It is crucial to expose children during the primary assessment to effectively assess their work of breathing. CCTPs should not be reassured by a normal or slow respiratory rate; this presentation may reflect significant fatigue and, therefore, signal the child is approaching respiratory failure. Infants and young children may have nasal flaring or pursed lips on inspection. These signs may be accompanied by grunting, which occurs when the child is trying to exhale against a partially closed glottis. Such a child is making a physiologic attempt to stent open the distal airways to improve oxygenation and ventilation, a process known as auto-PEEP (positive end-expiratory pressure). Because young infants are obligate nose breathers, the CCTP should assess for the presence of a significant nasal mucus burden, which can be a cause of significant respiratory distress.

Children having respiratory difficulties often assume a tripod position **FIGURE 24-10**, which allows the muscles of the anterior chest wall and neck to facilitate more effective ventilation. Respiratory distress rarely improves when the child is in a supine position. Moreover, as the stomach fills with excessive air (**aerophagia**) secondary to the increased respiratory rate, the child may be at a higher risk of vomiting and subsequent aspiration.



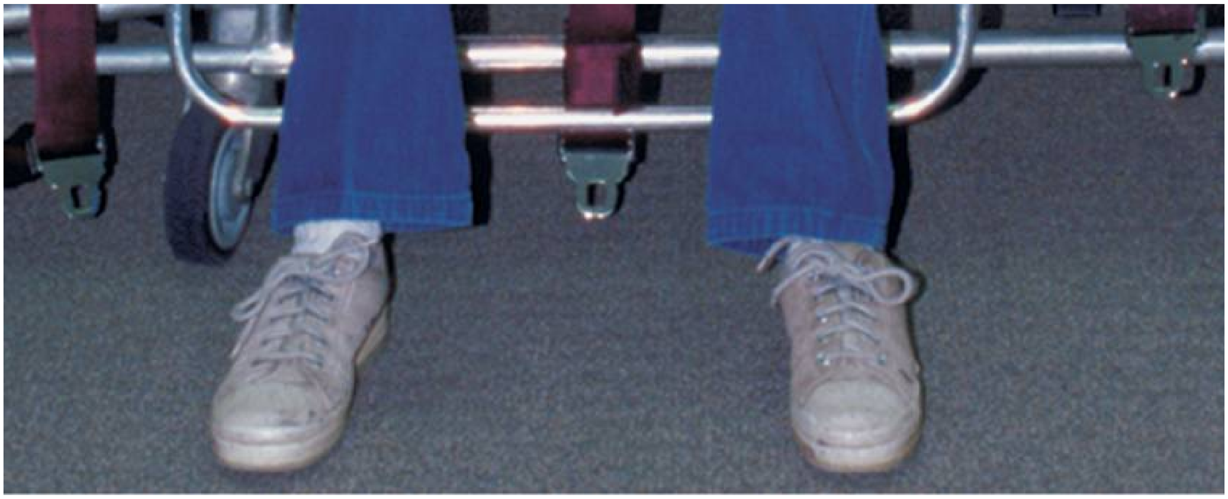


FIGURE 24-10 Children may assume a tripod position to maximize their use of the accessory muscles of respiration.

© American Academy of Orthopaedic Surgeons.

As part of determining the work of breathing, the CCTP may assess for stridor, snoring, retractions, head bobbing, accessory muscle use, tripoding, nasal flaring, wheezing, and grunting. In younger children, the diaphragm is the chief muscle used for ventilation; intercostal and accessory muscles are not fully developed until the child reaches school age. If the diaphragm fails in a young pediatric patient, the child may develop paradoxical breathing. This breathing pattern is best described as a seesaw motion, in which the abdomen and the chest move in opposite directions. As respiratory distress progresses, the respiratory rate may become slower and more irregular. Bradypnea (a slow respiratory rate) is a late sign of respiratory distress and predicts impending respiratory failure. In such a case, immediate interventions are required to prevent complete respiratory and cardiac collapse.

Children have a high metabolic rate and, consequently, a high oxygen demand. Oxygen demand for infants ranges from 6 to 8 mL/kg/min, which is twice that of adults (3 to 4 mL/kg/min). Coupled with their relatively poor reserves, children are at risk of developing hypoxia sooner than adults.

Hemodynamic monitoring (heart rate, pulse oximetry, respiratory rate, and end-tidal capnography) is an important adjunct to the assessment of a child with respiratory distress. However, CCTPs should always couple this information with their findings from the clinical assessment of the child. For example, a child in status asthmaticus for a prolonged period may have a normalization of the respiratory rate during the course of their exacerbation. If the child is speaking more comfortably and is more interactive, this trend is reassuring that treatments are effective. If the child's respiratory rate is decreasing and the child remains lethargic, this may be an ominous sign of impending respiratory failure.

The PAT can be used as a dynamic tool to continuously reevaluate the child's LOC, with particular emphasis being placed on the child's appearance, work of breathing, and circulation. A child with mild to moderate hypoxia may appear agitated and anxious. As the hypoxia progresses and is likely coupled with hypercapnia, the child may become quiet and sleepy. In such a case, do not be falsely reassured that the child is better. Key assessment points include whether the child can maintain and protect the airway. In addition, determine whether the child can maintain the current respiratory effort and determine the likelihood of deterioration en route to the treatment facility. It is imperative for the CCTP to monitor the patient's respiratory rate, pattern, oxygen saturation levels, and electrocardiogram (ECG) waveform for any changes in heart rate (tachycardia or bradycardia) or increased cardiac ectopic foci (premature atrial contraction, premature junctional contraction, or premature ventricular contraction).

Auscultation is the primary tool used to assess the adequacy of a child's respiratory effort. Auscultation begins during the initial assessment, while evaluating for overt signs of respiratory distress. The CCTP should evaluate for grunting, stridor, audible wheezing, and quality of the child's cough (eg, barky, bronchospastic, staccato). Children may exhibit the same adventitious breath sounds as adults, such as fine crackles, coarse crackles, rhonchi, wheezing, or a silent chest. When caring for young children, a common clinical mistake is failure to recognize the presence of transmitted upper airway sounds during auscultation of the chest. CCTPs should auscultate in front of the patient's nose/mouth and neck, progressing downward to the lung exam. The pulmonary exam frequently offers information to guide treatment.

CCTPs should take advantage of the various technological adjuvants that, when coupled with the history and physical exam findings, support the management of critically ill children. Oxygen saturation, as measured by pulse oximetry, and end-tidal carbon dioxide ($ETCO_2$) are ubiquitous measurements in emergency medical services (EMS) practice. Pulse oximetry readings indicate the percentage of hemoglobin molecules that are bound with oxygen, abbreviated SpO_2. As useful as this information is, CCTPs must remember that in some disease states, the SpO_2 value will remain normal even in the presence of significant physiologic abnormalities. A child with profound anemia may have an SpO_2 of 100% because all the hemoglobin molecules are saturated. However, if insufficient hemoglobin molecules are available, the end-organ tissues' needs for oxygen will not be met. Similarly, carbon monoxide poisoning can yield deceptive SpO_2 values. Carbon monoxide's affinity for hemoglobin is greater than oxygen's, so it readily binds to the hemoglobin molecule. Pulse oximeters cannot distinguish between oxyhemoglobin and carboxyhemoglobin, so they will give a falsely normal reading in case of carbon monoxide poisoning. Other factors that can interfere with the reliability of SpO_2 measurements include poor perfusion and coldness of the measured extremity.

Measurement of $ETCO_2$ is the standard of care for assessing adequate respiration in ventilated patients. Measurement of carbon dioxide, the by-product of respiration, is more reliable for measuring adequate gas exchange. $ETCO_2$ monitors are available for tracheal tubes and nasal cannulas. In children with poor mentation, monitoring $ETCO_2$ levels may provide the CCTP with insight into the child's ventilatory status. Normal values for $ETCO_2$ are 35 to 45 mm Hg, similar to the values found in arterial blood gas (ABG) samples.

ABG analysis may be available to the CCT provider. Its results can provide insights into the adequacy of ventilation and oxygenation efforts. However, numerous medications and physiologic states can alter the findings of an ABG analysis, thereby creating diagnostic confusion and leading to inappropriate intervention. The partial pressure values of carbon dioxide in an ABG analysis correlate well with end-tidal values, which are more commonly used by EMS providers. ABG values should be discussed with the medical control physician. Like other adjuvant measurements, they should be assessed as part of the clinical picture and not evaluated in isolation.

Circulation and Vital Signs

Physical assessment of a child's cardiovascular system begins with observing the child's general appearance and LOC. A child who is well perfused will be watching the CCTP and other activity in the room. Observation of the chest may reveal the child's heart beating through the skin (precordial activity); this can be a normal finding in pediatric patients. Assessment of the fingers and toes should be conducted to look for evidence of clubbing. **Clubbing** is the broadening of a child's fingers and toes in response to chronically low oxygen levels for longer than 3 months **FIGURE 24-11**.

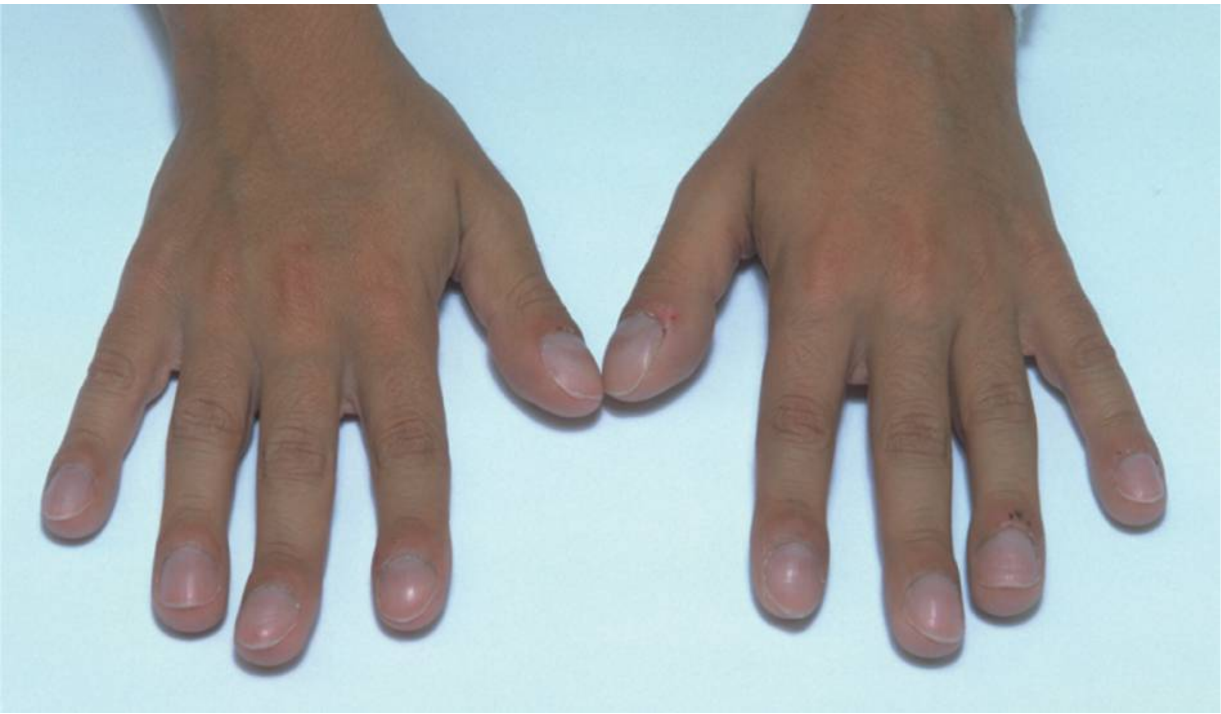

FIGURE 24-11 Clubbing.

As with an adult patient, evaluating respiratory status in a child should include an assessment of the pulse rate and quality, blood pressure, and capillary refill. The position of a child's heart in the thoracic cage is identical to that of an adult. When auscultating the pulse rate of an infant, it may be useful to place the stethoscope over the second intercostal space at the midclavicular line. For older children, auscultation may be easiest over the fourth intercostal space at the midclavicular line. Cardiac sounds should be absent of rubs, murmurs, gallops, and secondary sounds. Keep in mind that heart sounds heard over the apex of the heart represent precordial activity. Patients with poor cardiac output may not have strong peripheral pulses.

In young infants, the heart rate can be palpated by identifying the brachial artery in the medial upper arm or the femoral artery. In older children, assessment of the radial pulse becomes more reliable. Tachycardia may be present in a child with fever, pain, or anxiety but may also be a sign of infection, hypervolemia, or shock. The heart rate should be evaluated in the context of the clinical picture. A fast, thready pulse, coupled with other signs of poor perfusion (eg, mottled skin, prolonged capillary refill), is a worrisome finding.

BP readings should be taken with age- and size-appropriate equipment. Recall that BP will likely be normal even in children experiencing shock until they reach the very latest stages. Children with hypotension resulting from shock are in imminent risk for irreversible deterioration. A child with significant hypoperfusion may present with altered mental status, as insufficient systolic BP (SBP) reduces the cerebral perfusion pressure.

Mean arterial pressure (MAP) [calculated as (2 × diastolic BP [DBP] + SBP) / 3] offers valuable information about the end-organ perfusion and can be measured by invasive arterial line or a noninvasive BP monitor. These parameters ultimately reflect the child's cardiac output. Cardiac output in children, as in adults, is determined by stroke volume and heart rate. Children, especially younger infants, have a limited ability to increase stroke volume; ability to compensate is especially limited in children with volume loss or dehydration. In children, the primary means of increasing stroke volume is an increase in the heart rate. Children will maintain a normal BP because of the robust ability to increase their heart rate during times of physiologic stress. Be wary of the bradycardic child, who is likely in imminent risk for acute deterioration.

Doppler ultrasonography may be useful if the CCTP cannot palpate a pulse; however, if the pulse cannot be palpated, cardiac activity and perfusion are considered inadequate. In addition to assessing the presence and quality of pulses, compare the pulses bilaterally and in the upper and lower limbs. In a child older than 1 year, the pulse rate should be assessed in the carotid, radial, femoral, and dorsalis pedis arteries. To assess a pulse in an infant younger than 1 year, use the brachial and femoral arteries. Palpating carotid pulses in infants is difficult because of their thick, short necks. The carotid pulse is palpated only by hyperextending the child’s neck.

Point-of-care ultrasonography (POCUS) is another method for assessing cardiac function and volume status in the interfacility transport setting. POCUS should be performed only after appropriate training and credentialing by the agency’s medical director.

An evaluation of the child’s skin can provide valuable insights into the child’s circulation and may help identify hypoperfusion. Early compensatory mechanisms shunt blood from the skin to the vital organs. Skin that is well perfused should be warm, dry, and the appropriate color for that individual. As a child becomes hypoperfused, the skin becomes cool, pale, mottled, or cyanotic. If perfusion deteriorates further, the child’s hands and feet will typically be affected first. Clammy or diaphoretic skin may also be present in the child with poor perfusion.

Capillary refill is also an excellent indicator of peripheral perfusion. Normal capillary refill in pediatric patients is usually immediate; however, up to 3 seconds is considered an acceptable limit in a child who otherwise appears healthy. Capillary refill of greater than 4 to 5 seconds represents a significant delay. Keep in mind that ambient temperatures may affect capillary refill time; such differences are seen with hypothermia.

Blood Pressure

Children, at least initially, can maintain a normal BP despite other indicators of shock (eg, disproportionate tachycardia, prolonged capillary refill time, signs of altered mental status). They respond to physiologic stress by releasing catecholamines that cause vasoconstriction, an increased pulse rate, and increased cardiac contractility. As a result, children will maintain a normal BP until their compensatory mechanisms are depleted. For example, in case of hypovolemia, a child can lose as much as 25% to 30% of the total blood volume before hypotension is noted.

A common error when measuring BP in a child is not fitting the cuffs correctly. A cuff that is too large and exceeds two-thirds the length of the child's arm will give a falsely low reading; a cuff that is too small or is less than half the length of the upper arm will give a falsely elevated reading. Often, providers choose to measure BP in a lower extremity, because it is well tolerated by children. BP values obtained from the lower extremities have been shown clinically to correlate well with values obtained from upper extremities; however, it is advised that both upper- and lower-extremity BP values be documented to ensure correlation. Always consider the child's normal range and clinical condition. Pain, fear, and anxiety often increase a child's BP.

Where available, invasive arterial monitoring allows for precise BP measurements and may better identify trends than intermittent BP readings. For some disease processes, such as traumatic brain injury (TBI), the MAP may be a more important measurement than BP in guiding treatment. The MAP may be a better measure of end-organ perfusion and may be measured by either an arterial line or a noninvasive BP monitor.

Fluid Volume and Access

Understanding circulating blood volumes for children is useful for quantifying volume loss and calculating fluid replacements. An estimate of 80 mL/kg of body weight for a child's circulating volume is appropriate.

In a child in critical condition, any trauma or medical condition that causes fluid losses, such as bleeding, vomiting, urination, or insensible losses (those that cannot be quantified), requires IV access for volume replacement. IV access can be obtained via a peripheral or central route. The use of intraosseous (IO) access has become common in infants and children requiring urgent interventions with fluids, blood, or medications, in whom rapid venous access cannot be obtained. The most common site for IO insertion is the anterior tibia **FIGURE 24-12**. Alternative sites include the distal femur, medial malleolus, and anterior superior iliac spine. In adolescent patients, a humeral head location can be considered. Contraindications to IO access include, but are not limited to, **osteogenesis imperfecta** (also called brittle bone disease or Lobstein syndrome), **osteopetrosis**, evidence of infection at the potential insertion site, and fractures of the ipsilateral (same side) extremity.

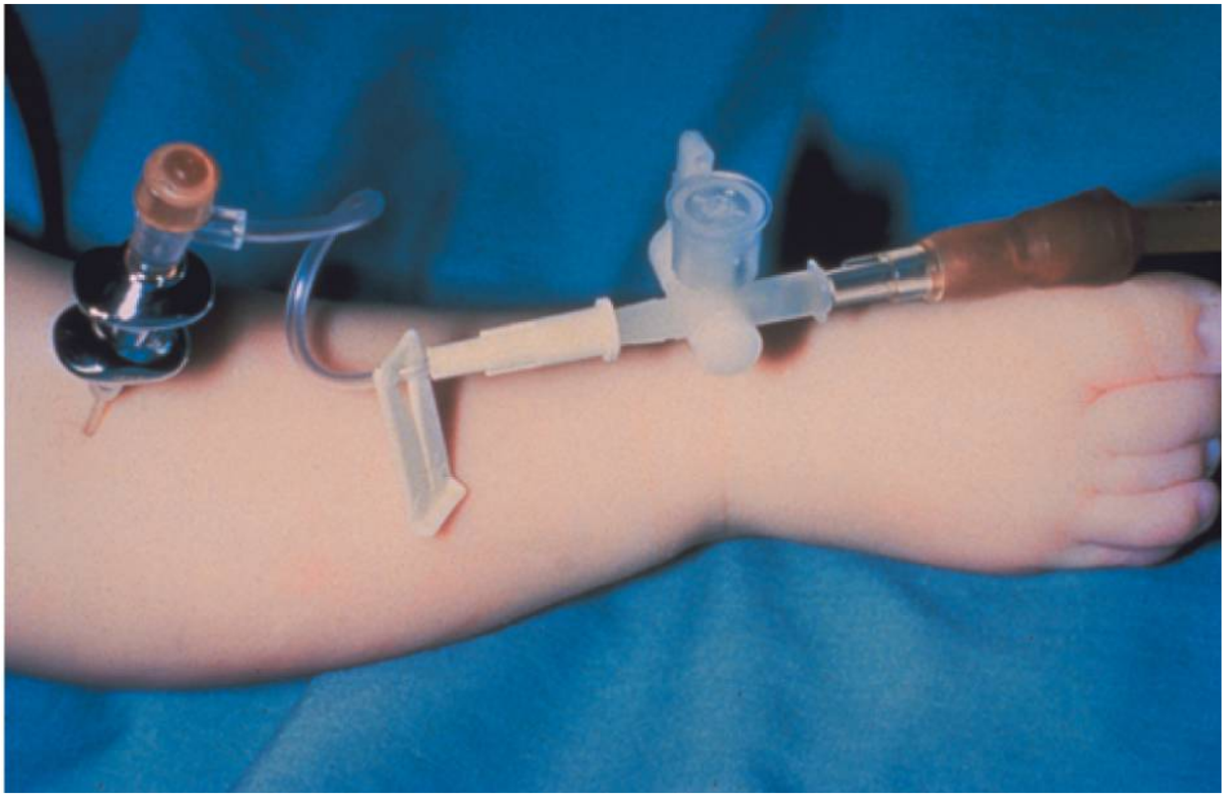

FIGURE 24-12 Standard pediatric intraosseous needle.

© American Academy of Orthopaedic Surgeons.

Additional IO devices include the EZ-IO and the Bone Injection Gun (BIG). The EZ-IO features a hand-held battery-powered driver, to which a special IO needle is attached **FIGURE 24-13**. This device is used to insert an IO needle into the proximal tibia of adults and children when IV access is difficult or impossible to obtain. The battery-powered driver of the EZ-IO is a standard piece, but different sizes of needles are available for adults and children. Providers should use IO insertion in children younger than 6 months, because higher rates of failure are associated with use of the EZ-IO in this age group.

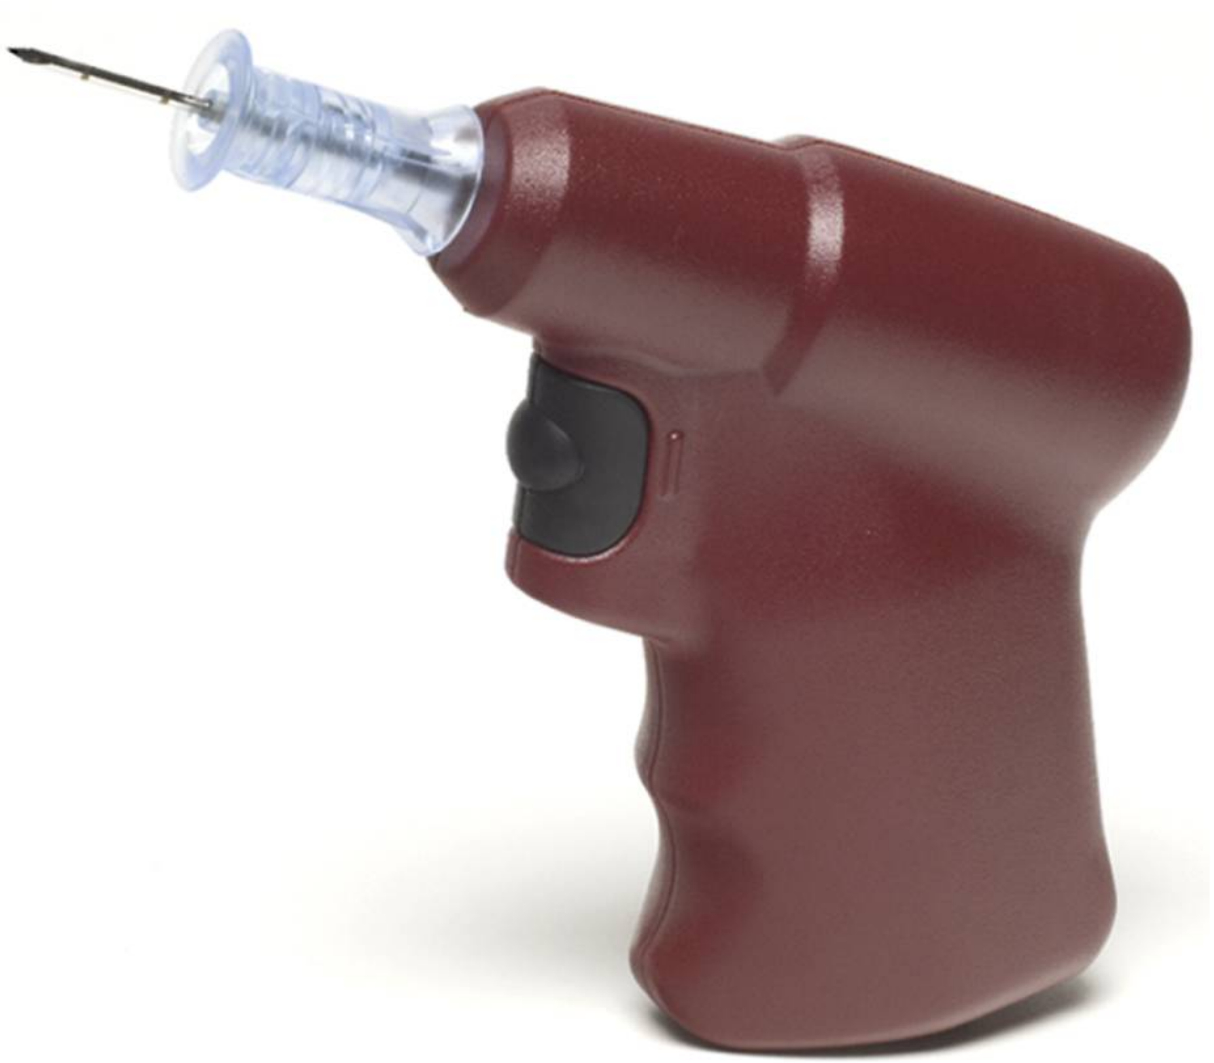

FIGURE 24-13 EZ-IO intraosseous infusion system.

The BIG is a spring-loaded device that is used to insert an IO needle into the proximal tibia of adult and pediatric patients. It comes in an adult size and a pediatric size **FIGURE 24-14**, although both versions offer the same operational features.

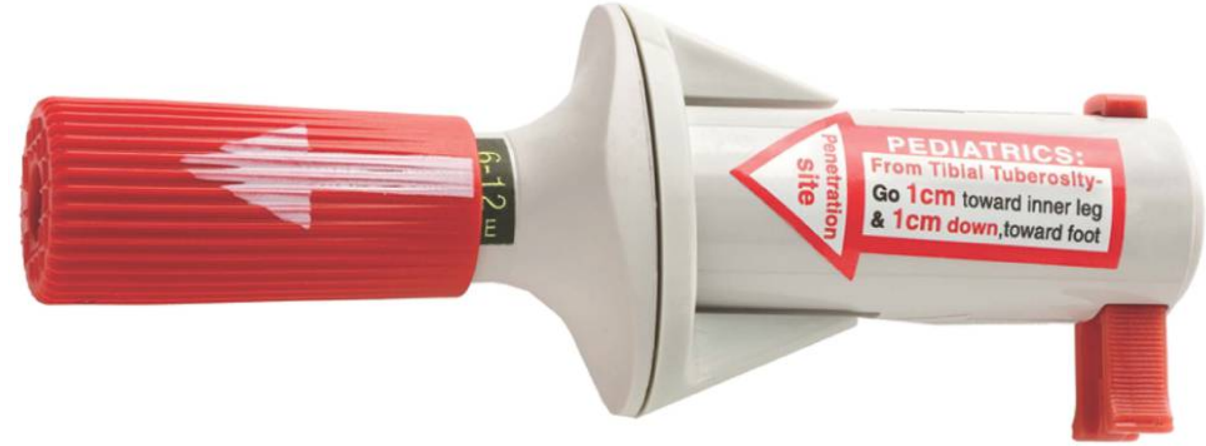

FIGURE 24-14 Pediatric Bone Injection Gun.

If the child shows any signs of hypovolemia, a 20-mL/kg bolus of normal saline should be given, and repeated as necessary, up to 60 mL/kg during transport. It is important to clinically reassess children after volume resuscitation, especially if the child has a history of cardiac disease or if providers suspect cardiac pathologies (eg, myocarditis, heart failure). This reassessment should include an evaluation for hepatomegaly and for the new presence of crackles, both of which may suggest right-side volume overload. In children with evidence of fluid-refractory shock, vasoactive medications should be considered, including boluses of epinephrine or phenylephrine, or initiation of vasoactive infusions.

In patients who have sustained trauma and have signs of refractory hemorrhagic shock, it is reasonable to initiate blood products after 40 mL/kg of volume resuscitation. This approach allows for ongoing volume resuscitation while minimizing the potential for coagulopathy associated with the nonjudicious use of normal saline during resuscitation of trauma patients. Blood replacement is typically administered in aliquots of 5 to 15 mL/kg. CCTPs should follow local protocols and guidance regarding the initiation of blood products during interfacility transport.

Urine output can be an objective guide when assessing pediatric circulatory status and the effectiveness of volume replacement. Signs of poor kidney perfusion include a low urine output. In children wearing diapers, low urine output is considered fewer than 4 to 6 wet diapers in a 24-hour period. In children with a urine catheter in place, it is considered less than 0.5 to 1 mL/kg/h. An adequate urine output is typically 1 to 2 mL/kg/h. An accurate assessment of urine output in the critical care setting can be made by comparing the weight of wet to dry diapers. This may be impractical in the transport environment, but attention to diapers provides information about renal perfusion.

Neurologic Assessment

As with other assessments of the pediatric patient, the neurologic evaluation will be age dependent. During the primary assessment, evaluate the infant's general appearance. Neonates' appearance can be deceptive, and a focused neurologic assessment can identify a potentially critically ill child. How is this child responding to the environment: is the child responsive or unresponsive, awake or lethargic?

Assessment of the fontanelles is important. A sunken fontanelle may indicate dehydration. A tense or bulging fontanelle may indicate increased intracranial pressure (ICP); that is, as the ICP rises above normal limits, the fontanelle allows for expansion.

Infants retain a number of intrinsic reflexes early in life. Chief among them is a strong suck. The sucking reflex can be evaluated by placing a gloved fifth digit into the infant's mouth with the palmar surface facing up. Healthy infants have a strong, well-coordinated suck. Absence of this reflex suggests a neurologic problem.

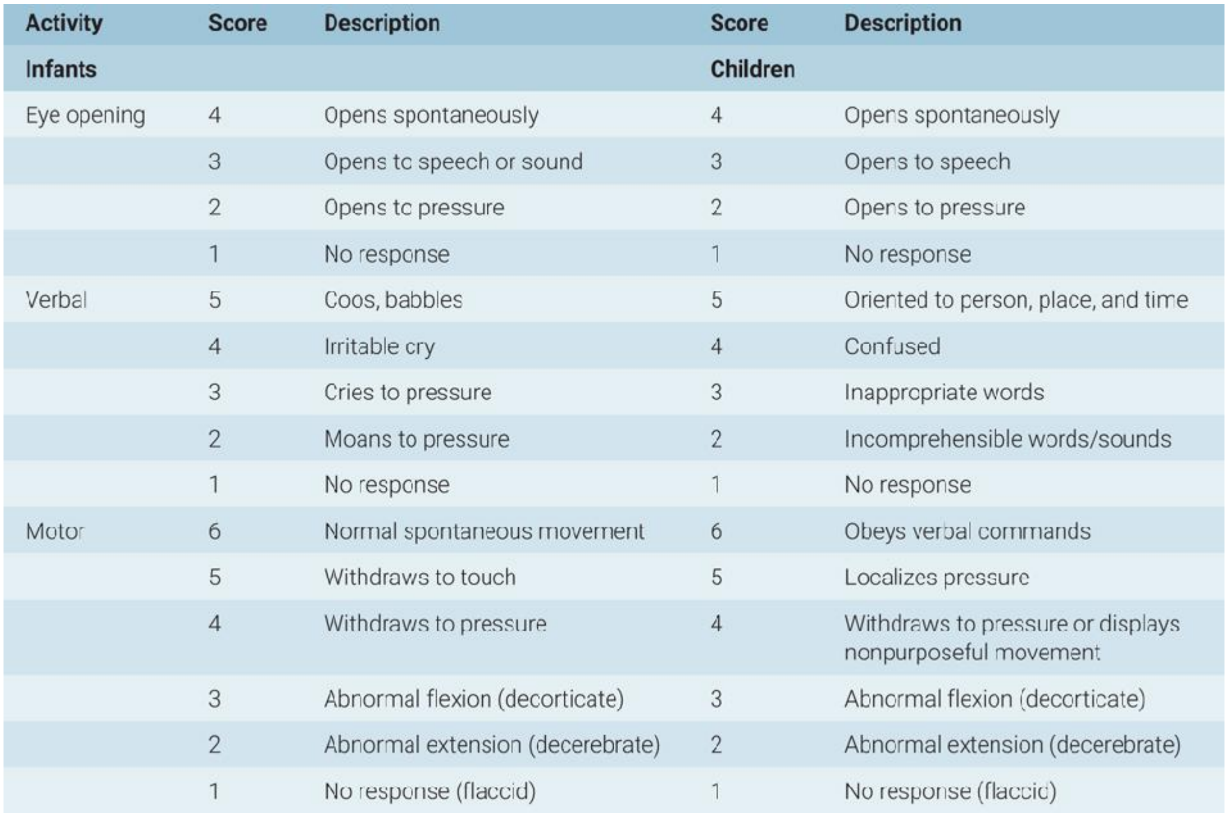
Healthy infants should have rigorous axial and peripheral tone. Axial tone can be evaluated by lifting the infant from under the armpits while supporting the head. Healthy infants will maintain this position; in contrast, children with poor axial tone will "slip like a fish" through the provider's hands, with arms extending upward. Regarding extremity tone, infants normally have flexed elbows and knees. Completely flaccid extremities are an abnormal finding. Another measure of motor function is the presence of normal reflexes, such as the **Moro reflex**, which occurs when the infant jumps or is startled in response to a loud noise. The **stepping reflex** occurs when an infant is held up in the air and moves the legs up and down as if marching.

In a toddler or school-age child, motor function is assessed by observing gross motor function and the degree to which the patient interacts with the surrounding world. Healthy children move all four extremities, with symmetric strength and ability. Minimal movements, especially in response to a noxious stimulus, should raise a concern for neurologic impairment. The assessment of an adolescent very much parallels that of an adult patient.

Mental status in children is determined by observing for age-appropriate behaviors and thought processes. Infants 1 month or older can typically track with their eyes and will begin to have a social smile. For toddlers, providers should observe the degree to which they interact with the caregivers, make eye contact, and respond appropriately to stimuli (positive and negative). School-age children can be evaluated in a similar fashion as adults, with questions that are tailored to their age.

The **Glasgow Coma Scale (GCS)** is a sensitive indicator of mental status and offers providers a convenient means to communicate a patient's status to other caregivers; it can also be used to guide treatment. While this scale was originally validated for trauma patients, use of the GCS as a dynamic evaluation of pediatric patients with serious medical problems has become commonplace in the CCT setting. The GCS is modified when examining infants and children **TABLE 24-5** or children who are intubated.

TABLE 24-5 **Glasgow Coma Scale**



Activity	Score	Description	Score	Description
Infants			**Children**	
Eye opening	4	Opens spontaneously	4	Opens spontaneously
	3	Opens to speech or sound	3	Opens to speech
	2	Opens to pressure	2	Opens to pressure
	1	No response	1	No response
Verbal	5	Coos, babbles	5	Oriented to person, place, and time
	4	Irritable cry	4	Confused
	3	Cries to pressure	3	Inappropriate words
	2	Moans to pressure	2	Incomprehensible words/sounds
	1	No response	1	No response
Motor	6	Normal spontaneous movement	6	Obeys verbal commands
	5	Withdraws to touch	5	Localizes pressure
	4	Withdraws to pressure	4	Withdraws to pressure or displays nonpurposeful movement

Description

Another important component of the neurologic assessment is checking the child’s pupil size and response to light. As with adults, very constricted or pinpoint pupils are consistent with opioid overdose. A single dilated pupil is consistent with brain injury.

In a child with a decreased LOC, the presence of protective reflexes can determine whether a child needs ET intubation for airway protection. The loss of protective reflexes occurs in ascending order—swallow reflex, cough reflex, gag reflex, and, finally, corneal reflexes. The cough and gag reflexes can be assessed by using a suction catheter to elicit a response.

Renal Assessment

Assessment of the renal system typically begins with evaluation of hydration status. The patient’s history is key to this assessment. Parents or caregivers can offer information about the amount of intake by the child and the number of wet diapers, voids, stools, and frequency of emesis.

Physical assessment of the child may include assessment of the fontanelles (for an infant), assessment of skin turgor, the presence or absence of tears when crying, and sunken eyes. The measurement of wet diapers may be somewhat subjective because parents may change diapers that are not completely saturated. A good question to ask caregivers is whether the diapers are *different* from the normal pattern. A more objective measurement is weighing diapers: 1 mL of urine equals 1 g of weight. Daily weights are also an objective measurement because they may be an early indication of fluid loss. Acute weight loss may be an early indication of fluid loss.

Fluid overload is much less common in children than in adults; however, it may occur in patients with congenital heart defects or renal insufficiency; in children undergoing aggressive volume resuscitation, especially in the context of capillary leak secondary to sepsis; or in children with hypo-albuminemia, as is seen in the context of nephrotic syndrome or protein-losing enteropathy. Signs of fluid overload in children may be vague and initially have a more subtle presentation than in adults. For example, in children with pulmonary edema, hypoxia and grunting are two early signs. Other early signs, such as tachypnea, a cough, and increased oxygen needs, may be discounted as having other etiologies because of their vague presentations. Later signs, which are more obvious, may include crackles and pink, frothy sputum associated with pulmonary edema. Pulmonary edema can be confirmed by plain radiography of the chest or, in the hands of a skilled practitioner, by point-of-care transthoracic ultrasonography, as discussed in Chapter 9, *Laboratory Analysis and Diagnostic Studies*. Additional signs of fluid overload include weight gain, edema, and history of intake greater than output.

Exposure Considerations

Temperature regulation is a concern in all patients, but especially in children. Environmental concerns regarding hypothermia or hyperthermia need to be addressed during the assessment. Because of an infant’s physiologic differences and inability to shiver, resuscitation of infants and children must include measures to maintain body temperature, while being careful not to overwarm the patient. The infant’s disproportionately large head represents a large percentage of body surface area, making infants particularly susceptible to hypothermia.

Hyperthermia is related to increased oxygen consumption. Children left in vehicles during hot, humid weather for extended periods are at increased risk for hyperthermia. Other risk factors include physical exertion (ie, athletics) and intoxication with drugs and alcohol, which impair heat dissipation. Hyperpyrexia, defined as body temperature of 106.2°F (41.2°C) or greater, is associated with severe viral or bacterial disease.

To minimize heat loss, replace blankets on areas of the child that have been assessed and increase the temperature in the transport vehicle. Be sure to leave heating/cooling measures in place in transport units while the patient is being prepared for transport.

Transport Considerations

Dedicated pediatric specialty teams are ideal for transporting the ill or injured child, but they may not always be available or fiscally feasible. Essential knowledge for CCTPs caring for children includes understanding differences in pediatric physical assessment, airway management, ventilator management, vascular access, fluid and medication administration, and specific illnesses and injuries that are common in children. Essential skills include pediatric hemodynamic monitoring, ICP monitoring, mechanical ventilation, and use of thermoregulation devices. It is helpful to practice any new skills using the equipment found on the vehicle in which you will be working. In addition, although didactic education is required, it cannot substitute for hands-on pediatric experience including, but not limited to, routine pediatric care, critical pediatric care, and experience with pediatric intubations. Professionals who anticipate caring for critically ill or injured children should consider partnering with professional colleagues who care for pediatric patients on a regular basis.

Equipment

The CCT team must ensure appropriate equipment is available when transporting pediatric patients **FIGURE 24-15**. Significant variation among agencies and states has existed regarding the requirements for pediatric-specific equipment. In 2021, the National Association of EMS Physicians released a position statement and accompanying resource document describing the recommended equipment for basic life support (BLS) and advanced life support (ALS) ambulances; however specific equipment recommendations for CCT ambulances are limited. ECG monitoring with pulse oximetry and end-tidal capnography is the standard of care for all intubated pediatric patients. It is important to carry various sizes of ECG leads, pulse oximetry probes, and BP cuffs to ensure accuracy when obtaining vital signs.

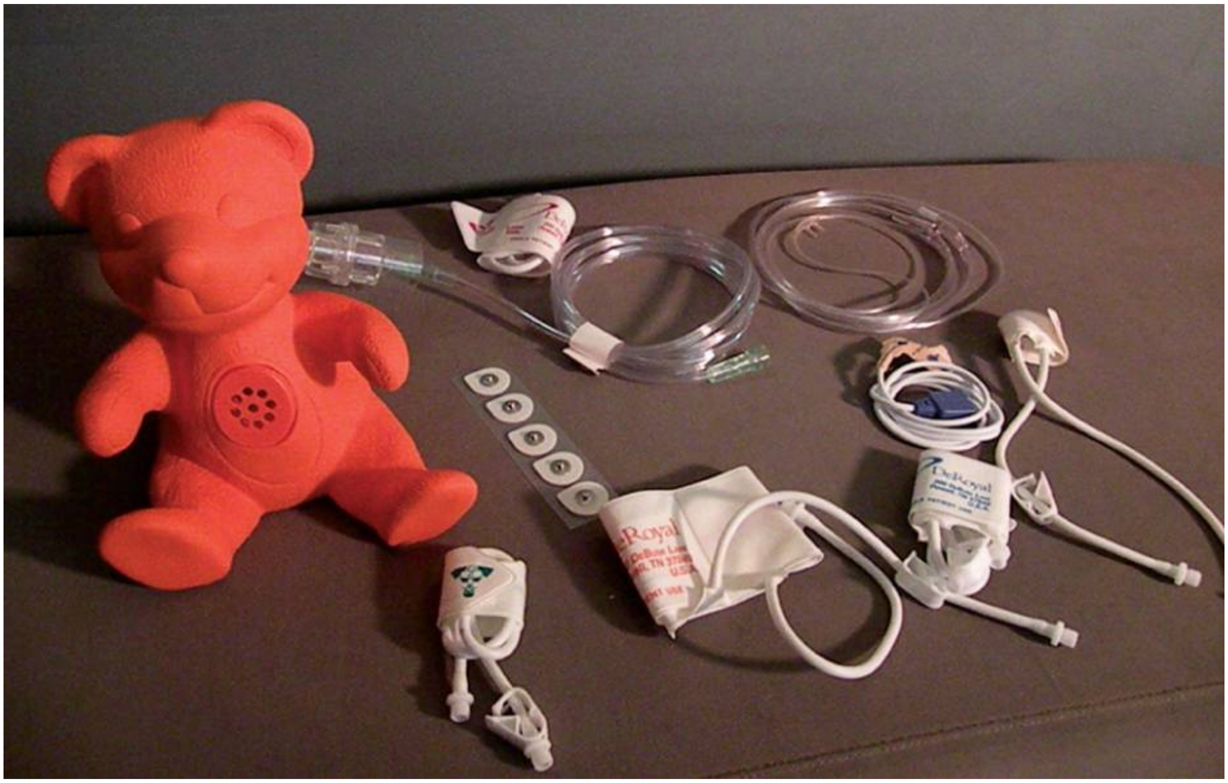

FIGURE 24-15 Appropriate-size equipment should always be accessible for transport of pediatric patients.

© Jones & Bartlett Learning.

IV fluid administration in pediatric patients should be done with an infusion pump that delivers medication infusions at a rate calibrated to at least one decimal place. Buretrol devices should be avoided because they are inaccurate and represent a latent safety threat. Fluid boluses and medications for resuscitation should be delivered with a syringe and stopcock technique. Fluid and medication formulas should be standardized and calculated prior to transport. It is also important to carry equipment for thermoregulation, such as a disposable gel-heated mattress or an incubator. Finally, know the capabilities of the transport ventilator for your service. Common requirements for ventilating children include pressure modes of ventilation, capacity for pediatric ventilator settings, and pediatric circuits.

CCTPs should consider maintaining a supply of single-use toys to help reduce anxiety during transport or to distract the patient, when appropriate, during procedures. Consider also the value of tablet devices for distraction of young patients.

Interfacility Transport Considerations

When you are conducting an interfacility transport, several important pieces of information will help to determine the mode of transport, the team configuration, and any specialized equipment that is needed. This information includes the age and weight of the patient, diagnosis, reason for transfer, physical exam findings, lab and other diagnostic test results, IV access, and consent. It is helpful to develop a standardized intake form that the transfer team can use in determining the need for airway management or other procedures to stabilize the patient for transport. For example, for patients with an altered mental status, ask the sending facility for the patient's GCS score and information on the presence of cough and gag reflexes to determine the need for emergent airway management. Any treatment recommendations must be recorded on the transfer documentation.

Once the CCTPs arrive at the sending facility, it is important to assess the patient immediately to determine the need for additional procedures prior to preparing the patient for transfer. Although it is important to ensure all lines and tubes have been secured and to double-check all fluid and medication rates, a standardized team approach to the patient care handoff is best. Using communication tools such as SBAR (situation, background, assessment, and recommendation) helps to standardize the exchange of information so that each provider has an expectation for what is to be discussed, even if the transport is time critical. This method can also be used to frame the conversation with other providers. Finally, a predeparture safety checklist ensures that the CCTP team has evaluated for potential safety threats (eg, equipment failure) and has had an opportunity to discuss any concerns for transport with either the referring physician or the receiving physician.

Mode of Transport

To ensure their safe transport, pediatric patients must be adequately restrained in the event of a motor vehicle (or flight) crash. Children should *never* be transported in the arms of a parent, guardian, or provider.

Particular attention must be paid to the positioning and placement of child passenger safety restraints. Devices for restraining infants and young children include an Isolette or similar product with attached straps to maintain body temperature, a child safety seat or a similar product that can be secured to the ambulance stretcher, and a pediatric immobilization device or backboard, although pediatric immobilizers are not approved by the Federal Aviation Administration.

While there are no federally approved standards for pediatric safety equipment, the National Highway Traffic Safety Administration has provided guidance and made recommendations for the safe ground and air transport of children. For young children, five-point restraints are recommended. For children older than 4 years, the standard stretcher straps may be used. Generally, a child who requires resuscitation should be positioned supine and secured to the stretcher. If there is no likely threat to physiologic stability, the child should be transported in an upright, secured position **FIGURE 24-16**.

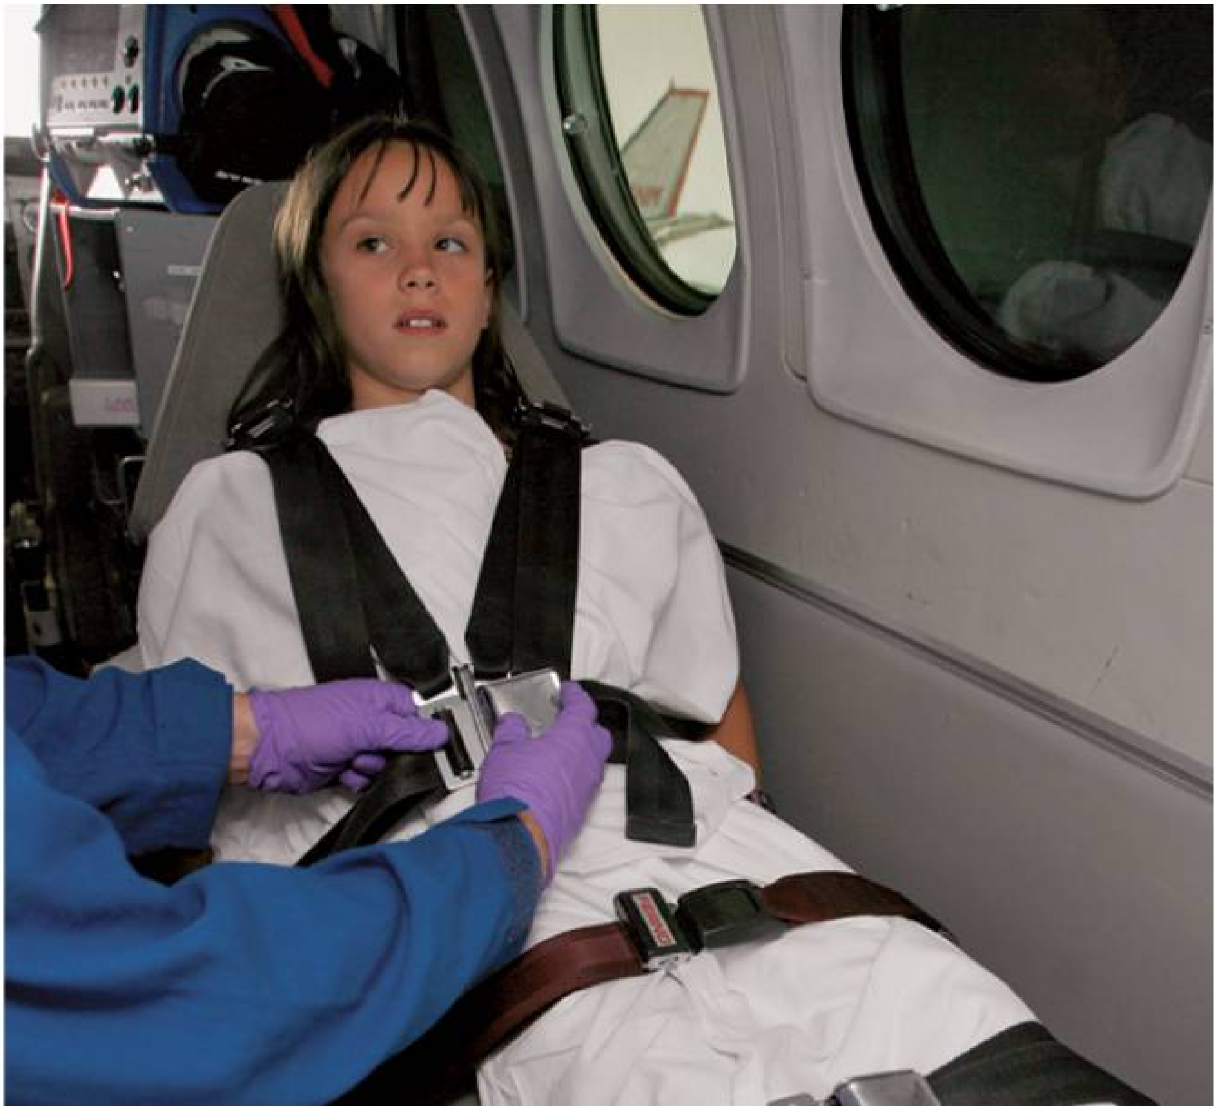

FIGURE 24-16 Transport the child in an upright, secured position if there is no likely threat to physiologic stability.

© Jones & Bartlett Learning.

Accompanying Parents and Caregivers

The decision to transport parents or caregivers along with a child should be discussed, and guidelines should be put in place long before a child needs transport. In general, the presence of a parent or caregiver decreases a child's anxiety and emotional distress, which may also have a positive physiologic effect. For example, if a child in respiratory distress becomes more anxious and upset because of separation from a caregiver, the child’s respiratory effort may increase and their physiologic status may deteriorate. The safe transport of the child has priority, however, and the caregivers’ comfort level and the potential for disruption of care during transport must be taken into account. Consideration must be given to the seating of the parent or caregiver, and guidelines should be discussed with the caregiver prior to transport—particularly the need to remain seated and restrained in a vehicle restraint. No child should ever be held on a caregiver’s lap for any reason while a vehicle is in motion.

Airway Management Devices

Several oxygen delivery adjuncts are used with pediatric patients in the critical care environment. These include devices commonly used in the prehospital environment, such as the nasal cannula, simple mask, partial rebreathing mask, nonrebreathing mask, Venturi mask, oxygen tent, and bag-mask device. Flow-inflating bags, self-inflating bags, and oxygen hoods are less commonly encountered in the prehospital environment and are discussed here for that reason. Supraglottic devices and ET tubes are the advanced airway management devices most commonly used in children. Shortened tracheal tubes and blade options for children are also discussed.

The American Academy of Pediatrics (AAP), in its Pediatric Advanced Life Support course, recommends that self-inflating bags be used for resuscitation. Therefore, most of this discussion focuses on self-inflating bags; however, a brief review of flow-inflating bags is provided as well.

Flow-Inflating Bag

Flow-inflating bags have been routinely used for anesthesia. These devices require an outside gas source to inflate them, and they have a pressure gauge port, a flow inlet dial, and an overflow port **FIGURE 24-17**. The volume of flow-inflating bags is 500 mL for infants and 600 to 1,000 mL for children. When these bags are inflated fully, providers can provide PEEP for the patient even without ventilations.

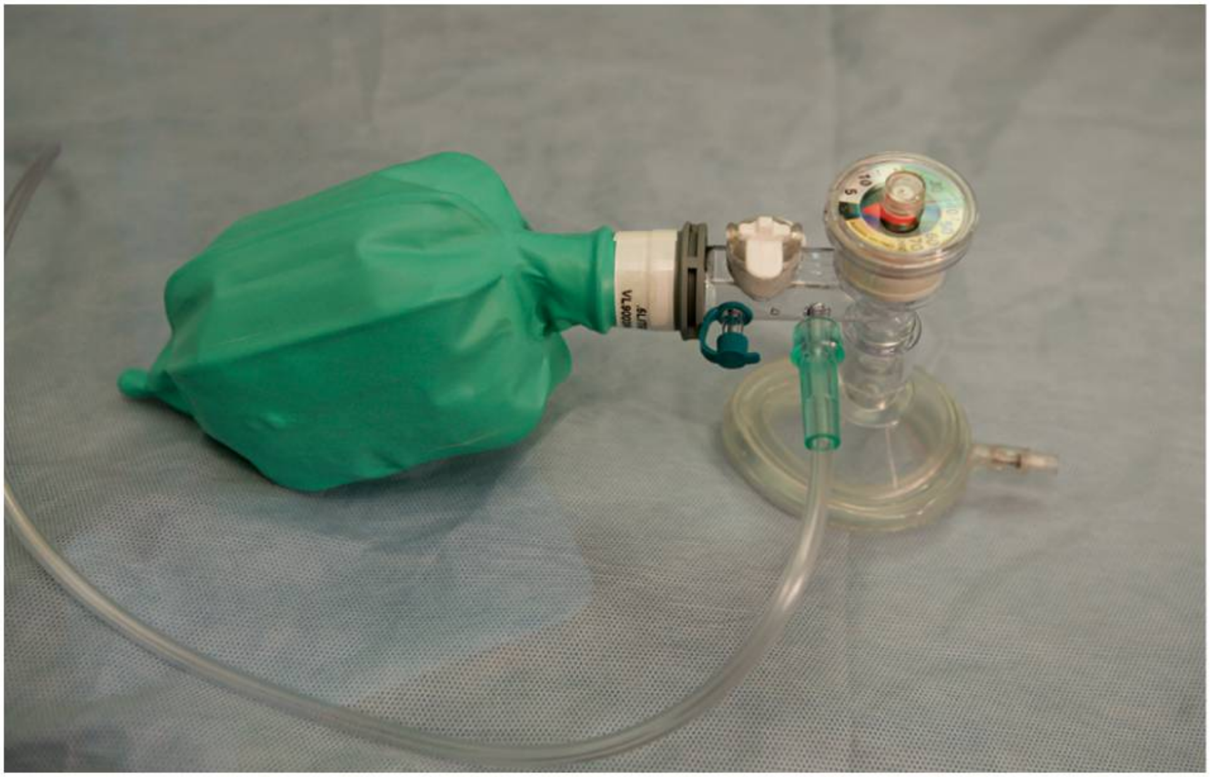

FIGURE 24-17 A flow-inflating bag.

© Jones & Bartlett Learning.

Self-Inflating Bag

Safe and effective ventilation is possible with self-inflating bags, although they require more experience and more manipulation of the equipment to achieve adequate ventilation **FIGURE 24-18**. Consequently, these devices are not recommended for resuscitation of infants and children unless the health care professional has received extensive training in their use.

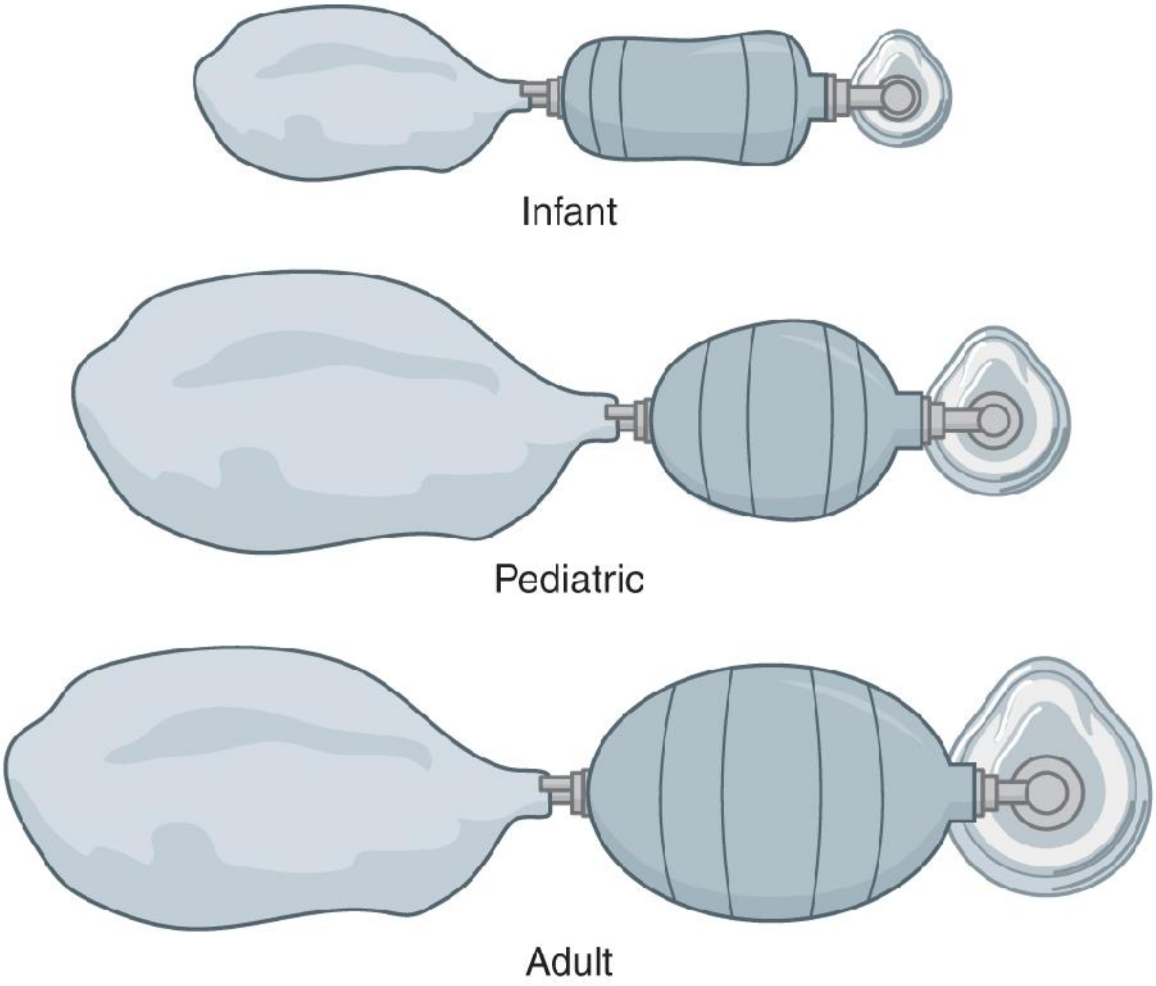

FIGURE 24-18 Self-inflating bags.

© Jones & Bartlett Learning.

Self-inflating bags come in different sizes to accommodate the various pediatric populations. A neonatal ventilation bag has a volume of 250 mL. Be cautious when using this device because the small tidal volume may be inadequate for term newborns and infants. As an alternative, CCTPs may use a pediatric ventilation bag, which has a minimum volume of 450 to 500 mL and a maximum volume of 750 mL.

Self-inflating bags do not require a compressed gas source and can deliver a free flow of oxygen. They have a pressure release valve (pop-off valve), a safety feature that releases gas when the pressure exceeds 40 cm H_2O. This helps to prevent excessive airway pressures while ventilating children and minimizes the complication of a pneumothorax.

When providing positive-pressure ventilation with a bag-mask device, use of a PEEP valve will help augment oxygenation and limit barotrauma. Additionally, pressure-relief valves (also called pop-up valves) are available on some bag-mask devices; these valves also reduce the risk of iatrogenic barotrauma. When the clinical situation requires higher pressures (eg, pulmonary edema), the pressure-relief valve can be released.

Oxygen Hood

An oxygen hood is an oxygen delivery system used in infant populations **FIGURE 24-19**. Children older than approximately 1 year are physically too big to fit in the oxygen hood. The hood allows for delivery of oxygen concentrations of 80% to 90% as well as humidified and warmed air. Oxygen delivery is reliable and allows for easy access of the child’s body. An oxygen hood is a passive form of oxygen delivery.

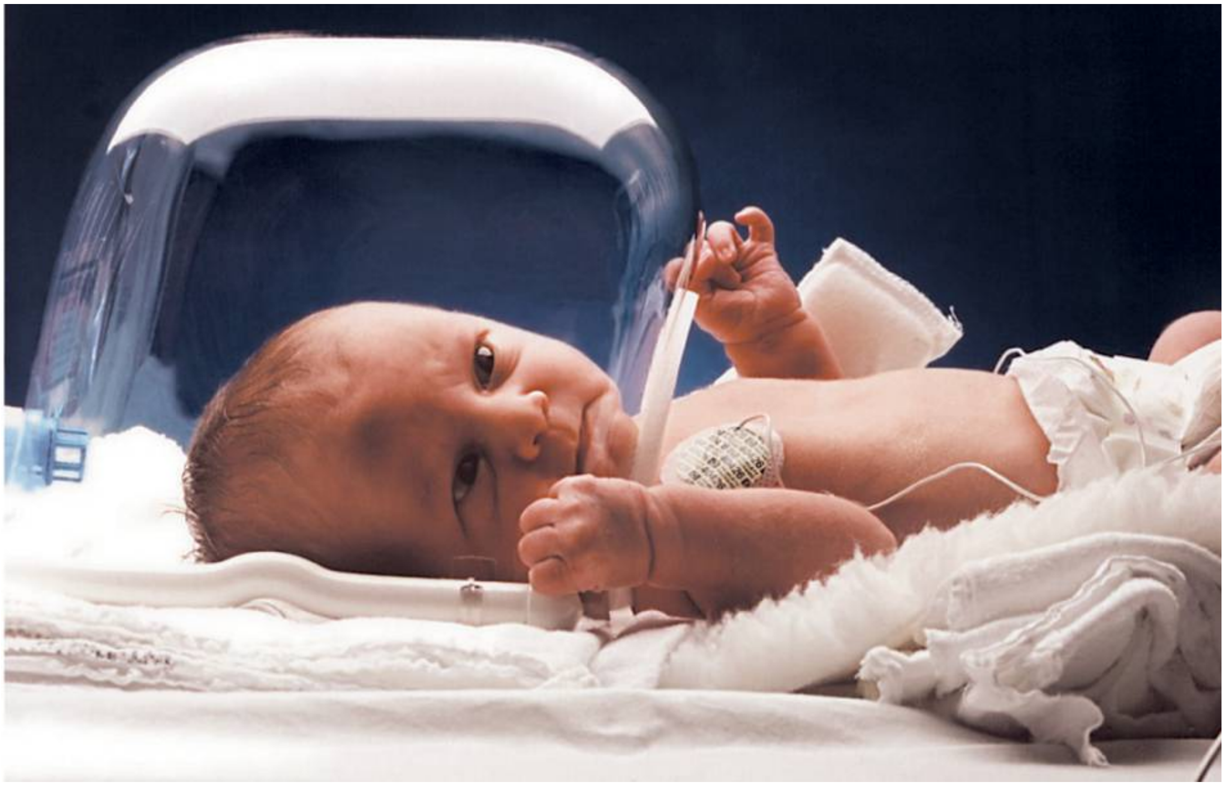

FIGURE 24-19 An oxygen hood.

Disposa-Hood™ Infant Oxygen hood. Courtesy of Utah Medical Products, Inc., Midvale, Utah.

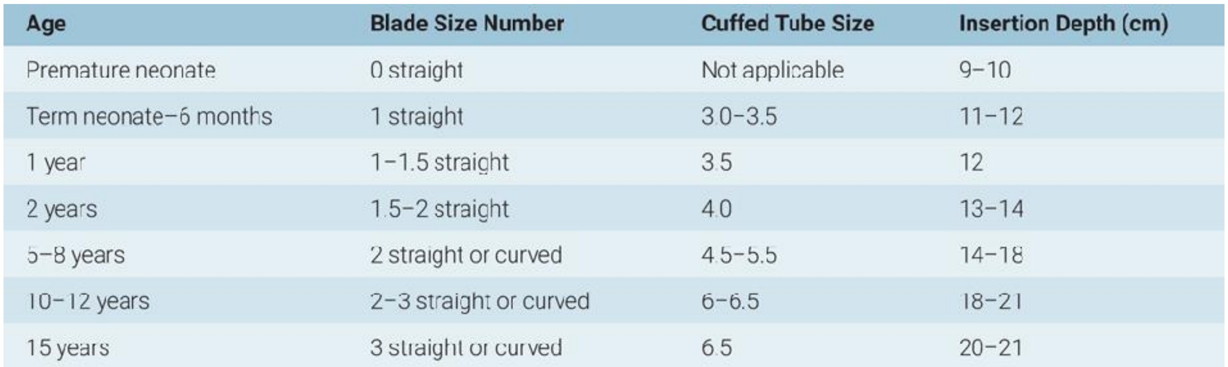
Blade Options

The laryngeal blade is available in two shapes: Miller and Macintosh.

- The Miller blade is a straight blade and usually the first choice for infants and younger children. A straight blade is preferred in these patients because the epiglottis is cephalad in position and the glottic opening is more anterior. Therefore, the straight blade allows better visualization for these anatomic considerations.
- The Macintosh blade is curved in shape and fits into the vallecula. This blade may be the preferred choice for older children and adolescents because it better displaces the relatively large tongue, thereby allowing better visualization of the glottic opening.

Actual blade size selection depends on the child's size, as opposed to age. **TABLE 24-6** offers some guidance on size selection.

TABLE 24-6 **Pediatric Laryngeal Blade Sizes**



Age	Blade Size Number	Cuffed Tube Size	Insertion Depth (cm)
Premature neonate	0 straight	Not applicable	9–10
Term neonate–6 months	1 straight	3.0–3.5	11–12
1 year	1–1.5 straight	3.5	12
2 years	1.5–2 straight	4.0	13–14
5–8 years	2 straight or curved	4.5–5.5	14–18
10–12 years	2–3 straight or curved	6–6.5	18–21
15 years	3 straight or curved	6.5	20–21

Description

ET Tubes

There are limited uses for uncuffed ET tubes for children. While some NICUs continue to use them in preterm infants, this practice is diminishing. It is preferable to place an appropriate-size cuffed ET tube when invasive ventilation strategies are warranted. Providers capable of advanced airway management in children during CCT should consider the following precautions:

- Where possible, secure the airway prior to departure from the referring site.
- Consider alternative airways and rescue airway devices (eg, supraglottic airway devices).
- Restrict airway attempts to the most skilled and experienced provider.

Respiratory Conditions

Respiratory illness is a common reason for pediatric transport. Respiratory compromise or failure can be caused by any airway, pulmonary, or neuromuscular disease that interferes with oxygen and carbon dioxide exchange. Respiratory conditions are often classified as either respiratory distress or respiratory failure.

Respiratory distress is characterized by a noted increase in the work of breathing. The dyspneic child is recognized by an increased rate (tachypnea) and possibly depth of breathing. Nasal flaring, retractions, and accessory muscle use are usually noted. Although the amount of effort to breathe is dramatically increased, the child may still have adequate gas exchange of oxygen and carbon dioxide. In addition, this change in the respiratory pattern may represent physiologic compensation to an underlying metabolic derangement. For example, in diabetic ketoacidosis, an increased respiratory rate and depth (Kussmaul breathing) is necessary to clear excessive amounts of carbon dioxide.

Respiratory failure is characterized by inadequate oxygen intake or inadequate exchange of oxygen and carbon dioxide. No specific definition of respiratory failure exists because this diagnosis depends on the child’s baseline respiratory function. Intervention to prevent respiratory and subsequent cardiac collapse is paramount for this patient population. If known risks are identified for respiratory failure in the patient prior to departing the referring facility or if the patient’s signs and symptoms worsen while en route to the receiving facility, the CCTP should take all measures (per protocol) to maintain and preserve a patent airway and hemodynamic status. It is possible for a patient to experience respiratory failure without signs of respiratory distress. For example, a child who is unconscious and apneic after a traumatic head injury will not demonstrate increased work of breathing but rather inadequate or absent breathing.

Respiratory conditions that lead to respiratory failure can be classified as an upper airway condition, a lower airway condition, parenchymal disease, or disordered breathing. Upper airway obstructions are most commonly caused by foreign body aspiration or infection and are characterized primarily by inspiratory stridor. Obstructions at the level of the vocal cords may lead to biphasic stridor, and obstructions in the trachea may have an expiratory component. Partially obstructed airways cause turbulent airflow. The obstruction can be above or can include the glottis, pharynx, and trachea. In such a case, the child’s voice will be muffled or hoarse. If the obstruction is subglottic or subtracheal, stridor will be present but the child’s voice may sound normal.

Lower airway disease may include the trachea and main stem bronchi as well as the peripheral airways. Lower airway aspiration most commonly occurs in children younger than 3 years. A diagnosis of lower airway disease is often made after aspiration, with the presentation potentially ranging from mild coughing and wheezing to severe respiratory distress.

Peripheral airway diseases that are common indications for transport include asthma, bronchiolitis, and bronchopulmonary dysplasia.

Croup

Croup (laryngotracheobronchitis) is a common viral infection of the upper airway that affects the larynx but may also extend into the trachea and bronchi. Symptoms include a low-grade fever and a hoarse, “barking seal” cough that often becomes worse at night. Children may also present with inspiratory stridor. Stridor at rest is particularly concerning for severe disease. Croup is most common in children younger than 3 years. In these children, the diameter of the cricoid area is at its smallest, so swelling may cause severe symptoms. Children most commonly present with mild distress, but severe respiratory effects have also been reported. The CCTP should be familiar with the hallmark sign of croup—namely, the harsh, “barking seal” cough.

Management of croup depends on the severity of the child's symptoms. A child in mild distress may be best managed by maintaining a calm environment. Humidified oxygen is the initial therapy. Allow the parents to sit next to the child to hold the humidified oxygen to the child's face using a mask or blow-by method.

For children with stridor at rest, a continuous barky cough, and/or signs of respiratory distress, racemic epinephrine (2.25% with 2.0 to 3.5 mL of normal saline) administered via a nebulizer usually improves airflow. The following dosages may be given:

- Age <6 months: 0.25 mL
- Child: 0.5 mL
- Adolescent: 0.75 mL

Racemic epinephrine is subtly different in chemical makeup from epinephrine, and it stimulates both alpha and beta adrenergic receptors, with a preference for the beta-2 adrenergic receptors that cause bronchodilation. The vasoconstrictive effects of racemic epinephrine are temporary, however, and persist only until the drug is metabolized, a factor that should be considered with long transport times. Once the drug is metabolized, the swelling ("rebound worsening") may return to the same level as before or may worsen. Services that do not carry racemic epinephrine may instead use L-epinephrine (1 mg in 1 mL), dosing it at 0.5 mL/kg (maximum dose, 5 mL) and combining it with 2 mL of normal saline for nebulization.

Children with refractory croup may benefit from Heliox, a gas that combines helium and oxygen. Heliox reduces turbulent airflow through narrowed airways. It is typically delivered in one of two mixtures: 80% helium and 20% oxygen, or 70% helium and 30% oxygen. CCTPs should be aware that the 80:20 mixture is a *hypoxic* mixture and should be used with caution in patients with borderline saturations. Additionally, the CCTP should consider noninvasive positive-pressure ventilation methods, such as continuous positive airway pressure (CPAP) or bilevel positive airway pressure (BPAP), to support the patient. A special consideration with CPAP or BPAP is the ability to provide in-line nebulization for continued administration of racemic epinephrine.

Signs and Symptoms

Croup

- Low-grade fever
- Hoarse, “barking seal” cough
- Mild distress
- Stridor

Differential Diagnosis

Croup

- Acute laryngeal fracture
- Allergic reaction/anaphylaxis
- Angioneurotic edema
- Arnold-Chiari deformity
- Bacterial tracheitis
- Burns or thermal injury
- Dandy-Walker syndrome
- Diphtheria
- Epiglottitis
- Extrinsic obstruction by a vascular ring
- Foreign body
- Laryngeal papillomatosis
- Laryngomalacia
- Neoplasm or hemangioma
- Peritonsillar abscess
- Retropharyngeal abscess
- Smoke inhalation
- Subglottic stenosis
- Viral croup
- Vocal cord paralysis

Transport Management

Croup

- Administer humidified oxygen using a mask or blow-by method.
- Consider corticosteroids (if not previously administered).
- For more severe obstruction, administer racemic epinephrine via a nebulizer.
- Consider Heliox for refractory croup.
- Apply noninvasive positive-pressure ventilation strategies.
- If the child is no longer able to protect the airway, consider oral intubation.

Early administration of systemic corticosteroids reduces the severity and duration of croup. Dosing of dexamethasone is usually 0.2 to 0.6 mg/kg (maximum dose, 16 mg), and this medication can be administered orally, intramuscularly, or IV. In children with severe disease and those requiring intubation, scheduled steroids should be considered. Alternative steroids include prednisolone, prednisone, and methylprednisolone.

In the rare circumstance in which the obstruction is so severe that the child is no longer able to protect their own airway, oral intubation may be considered. When you suspect that the airway is edematous, the size of the ET tube chosen may be one-half to one size smaller than the tube typically used.

Epiglottitis

Epiglottitis (also called supraglottitis) is most commonly caused by a bacterial infection with *Haemophilus influenzae*. Historically, this infection occurred most commonly in children ages 3 to 5 years. With the approval of the *H influenzae* type b (Hib) vaccine in 1991 and its widespread administration to infants, epiglottitis is now seen primarily in adults. Symptoms include rapid onset of fever, stridor, and pronounced signs of toxicity. The patient may appear anxious, have a muffled voice, and be in a tripod position with pronounced drooling because of supraglottic swelling and excess secretions. Remember the four Ds for epiglottitis: dysphagia, dysphonia, drooling, and distress. Patients with epiglottitis are at a tremendous risk of acute and complete airway obstruction. Invasive procedures should be kept at a minimum so as not to aggravate and increase the child's work of breathing.

Management of suspected epiglottitis in the prehospital setting is controversial because this condition can worsen rapidly, leading to a complete airway obstruction. The use of racemic epinephrine with this condition is contraindicated because it can cause additional swelling of the affected inflamed tissues. There is consensus that a calm environment should be maintained so as not to precipitate complete obstruction. There is also agreement that a definitive airway should be secured prior to transport. However, children with epiglottitis are often difficult to intubate and may require specialized teams or specialized techniques, such as retrograde intubation, direct bronchoscopy, or possibly tracheostomy, if intubation is unsuccessful. Therefore, the decision to attempt definitive airway management in the prehospital setting is multifactorial, with key considerations including EMS protocols, the skill and experience of the CCT team, and the time and distance of the transport. If intubation needs to be performed, it should be carried out by the most skilled practitioner. Ideally, intubation will occur in the operating room by a subspecialist with the expertise to perform a surgical airway.

Signs and Symptoms

Epiglottitis

- Rapid onset of fever
- Stridor
- Pronounced signs of toxicity
- Distress
- Muffled voice
- Drooling
- Tripod position

Differential Diagnosis

Epiglottitis

- Bacterial tracheitis
- Foreign body ingestion
- Mononucleosis
- Anaphylaxis
- Croup or laryngotracheobronchitis
- Pertussis
- Pharyngitis
- Pneumonia
- Peritonsillar abscess
- Retropharyngeal abscess
- Caustic ingestion

Transport Management

Epiglottitis

- Maintain a calm environment.
- Secure a definitive airway prior to transport.
- Ensure early antibiotic therapy

Foreign Body Airway Obstruction

Foreign body airway obstruction remains a significant source of morbidity and mortality in pediatric populations. Its onset may be dramatic, posing an immediate life threat or having varying severity.

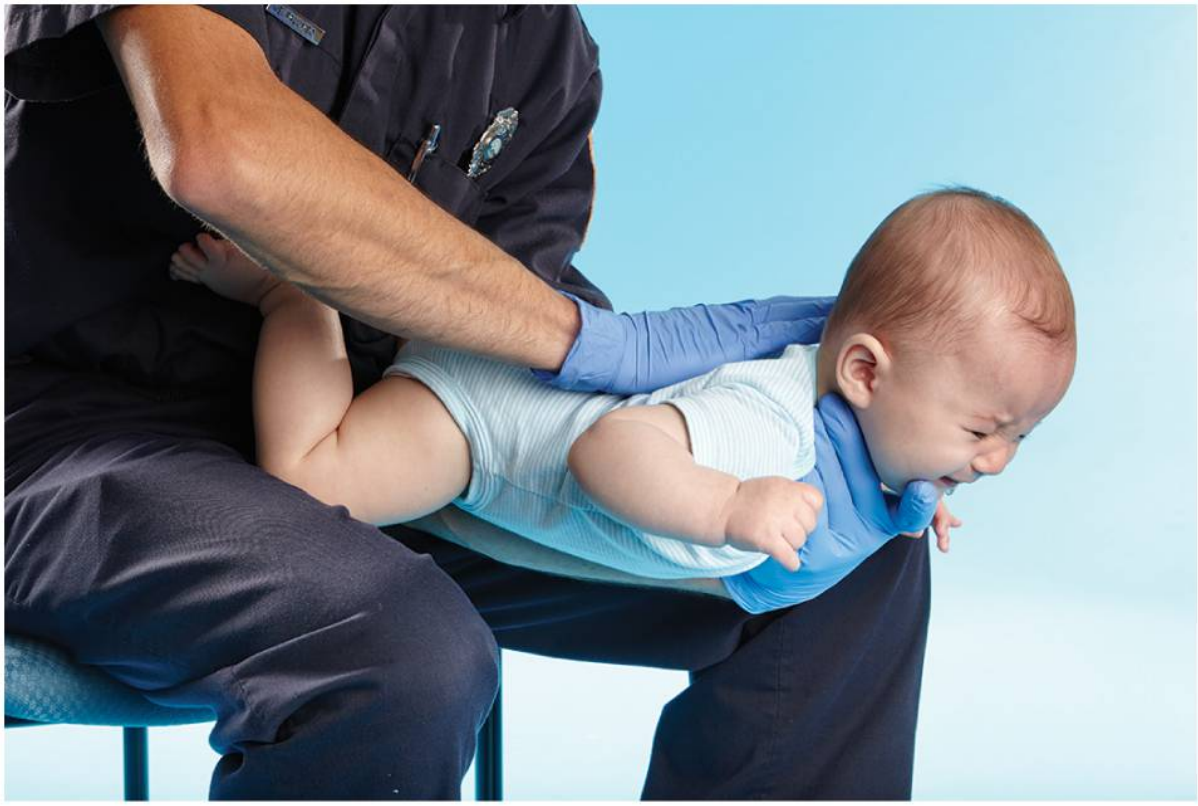
Removal of the foreign body should be attempted only in the prehospital setting by following the guidelines set forth by the American Heart Association (AHA) and AAP. These guidelines include the use of chest thrusts in infants and abdominal thrusts in older children, leading to direct laryngoscopy with Magill forceps to remove the foreign body. Specific algorithms should be followed **FIGURE 24-**

20. Direct visualization of the trachea and removal of the foreign body should be considered only in the event of impending respiratory failure.

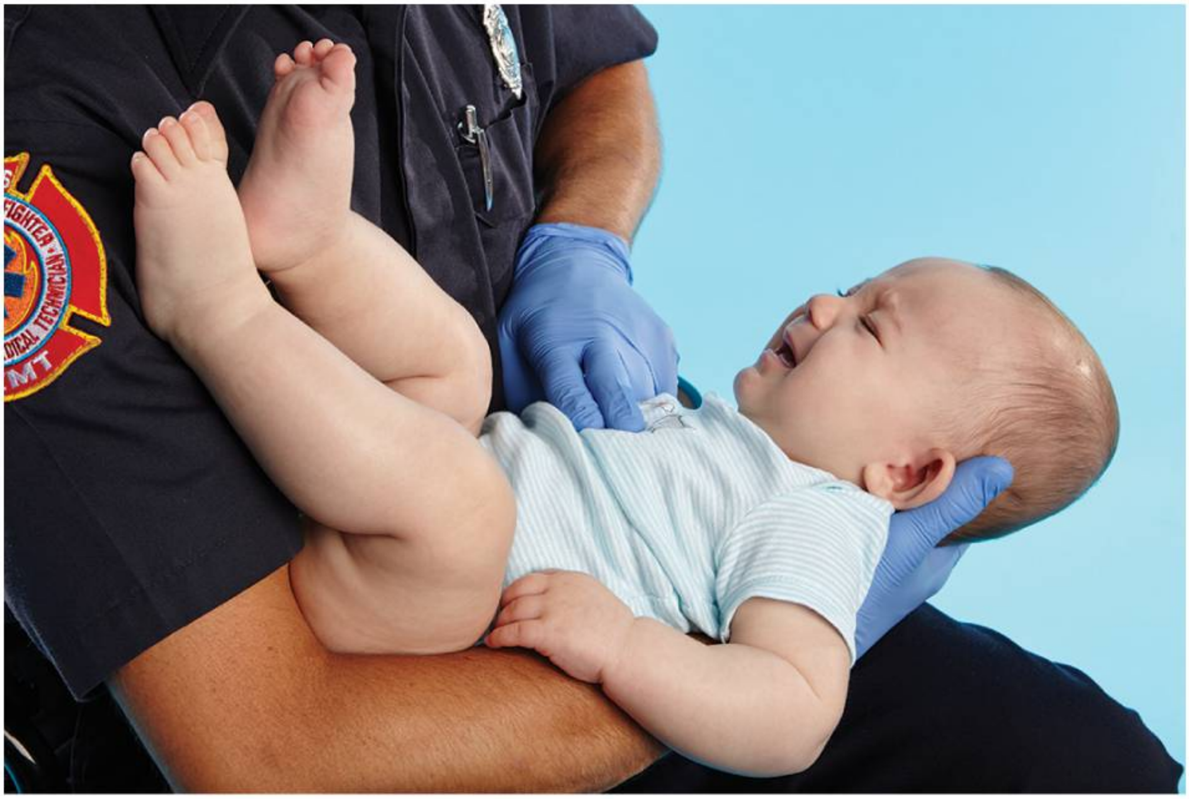
CONTROVERSIES

Some organizations have suggested the initial use of back blows in adults with a foreign body airway obstruction and an ineffective cough. However, this recommendation is weak and supported by only low-certainty evidence. Some experts argue against the use of back blows in larger patients due to the simple impracticality of this procedure: The provider can hold an infant with the head downward while giving back blows, allowing gravity to help draw the object out of the airway. The provider cannot likely position an adult in an inverted position while giving back blows, meaning that as the back blows dislodge the object, gravity may pull it downward, deeper into the airway.

Always follow your local protocols and contact medical control for direction when needed.



A



B

FIGURE 24-20 Back blows are typically recommended for infants (children younger than 1 year). **A.** Hold the infant facedown with the body resting on your forearm. Support the jaw and face with your hand, and keep the head lower than the rest of the body. Give the infant five back blows between the shoulder blades, using the heel of your hand. **B.** Give the infant five quick chest thrusts, using two fingers placed on the lower half of the sternum.

© Jones & Bartlett Learning.

Signs and Symptoms

Foreign Body Airway Obstruction

- Choking or gagging when the object is first inhaled or swallowed
- Sudden onset of coughing or cough that gets worse
- Stridor
- Wheezing
- Inability to speak
- Pain in the throat or chest
- Hoarse voice
- Blue around the lips
- Not breathing
- Unconscious

Differential Diagnosis

Foreign Body Airway Obstruction

- Asthma
- Croup
- Myocardial infarction
- Anaphylaxis
- Acute epiglottitis

Transport Management

Foreign Body Airway Obstruction

- Removal of the foreign body is attempted only following AHA and AAP guidelines: chest thrusts in infants or abdominal thrusts in older children.
- Direct laryngoscopy with Magill forceps.
- Back blows for infants younger than 1 year.
- Direct visualization of the trachea and removal of the foreign body only in the event of impending respiratory failure.

Inflammation

Generalized inflammation of the upper airway may be a result of inhalation burns or allergic and/or anaphylactic reactions. These airway insults are often precipitous in their presentations; early recognition and intervention are imperative to lessen morbidity and mortality. Therapeutic measures to treat all upper airway obstructions include the basics of ensuring a calm environment, administering supplemental humidified oxygen, providing a position of comfort, and preparing for deterioration of the airway status.

Bronchiolitis

Bronchiolitis is an inflammatory condition of the lower respiratory tract that results from viral infections, most commonly from the respiratory syncytial virus (RSV). Bronchiolitis begins with a viral upper respiratory tract prodrome (ie, nasal congestion, rhinorrhea, and often fever). Significant mucus production and edema in the nasal passages progress to involve the lower respiratory tract. Although wheezing is common initially in children younger than 2 years with bronchiolitis, this condition can also present with retractions, noisy breathing, and poor feeding.

The treatment for bronchiolitis is mainly supportive. Patients who are hypoxic or tachypneic may benefit from supplemental oxygen delivered via low-flow or high-flow nasal cannula and may require positive-pressure ventilation. Aggressive pulmonary toileting (ie, methods used to clear mucus from the airway) can be helpful, with saline and nasal suctioning as the mainstay treatments. Deep suctioning of the trachea or lower airways has fallen out of favor and may be harmful.

Bronchiolitis is a pathology of mucus production and inflammation. As such, the wheezing sometimes noted is not bronchospastic. Generally, there is no role for bronchodilators or steroids in patients with bronchiolitis. However, in children older than 18 months who have a strong family history of asthma or atopy, a trial of albuterol may be appropriate. If there is no significant improvement with albuterol therapy, further bronchodilators should not be attempted. Dehydration is common with bronchiolitis, and patients frequently require IV fluids.

Signs and Symptoms

Bronchiolitis

- Mild wheezing
- Tachypnea
- Noisy breathing
- Nasal flaring
- Retractions

Differential Diagnosis

Bronchiolitis

- Asthma
- Gastroesophageal reflux
- Foreign body aspiration
- Vascular ring
- Enlarged adenoids
- Heart failure
- Chronic lung disease

Transport Management

Bronchiolitis

- Administer supplemental oxygen and fluids.
- Provide aggressive pulmonary toileting.
- Suction as needed.
- Assess the child’s work of breathing before and frequently during transport.

Asthma

Wheezing is common in young children, especially those with hyperreactivity of the lower airways in response to stimuli such as allergens, exercise, infections, and exposure to cold air. This symptom, over time, may become suggestive of asthma, a chronic inflammatory condition that produces significant inflammation, bronchospasm, and edema in the lower airways. Recurring episodes present with shortness of breath, wheezing, and chest tightness. Asthma frequently occurs in parallel with eczema and allergies, a presentation known as the atopic triad.

Reactive airway disease (RAD) is a term often used synonymously with asthma in younger children. RAD occurs in children younger than 3 years; in 30% of children with RAD, the condition will progress to asthma. As of 2018, nearly 5.5 million children in the United States, or 7.5% of the pediatric population, had asthma. Asthma exacerbations are a frequent reason for EMS calls, ED visits, and admission to the hospital and intensive care unit for children.

Asthma is described as intermittent or persistent. Persistent asthma is further differentiated as mild, moderate, or severe, based on the frequency of symptoms and the need for controller medications.

Parents of children who experience chronic exacerbations of asthma are usually successful at treating the symptoms or preventing rapid deterioration while at home. Typically, when CCTPs are needed to transport a child with an exacerbation of asthma, traditional treatments have failed and more advanced therapies are required. In such a case, the CCTP should obtain a history from the child and parents or caregivers at the referring facility if they are available, and also obtain a detailed report from the transporting EMS crew (if available), the bedside nurse, and/or the referring physician. For example, if a child has a history of requiring numerous intubations for severe asthma, the child should receive all available treatments during rapid transport to the hospital.

Care for a child with an asthma exacerbation includes oxygen therapy because this condition is characterized by a significant ventilation/perfusion mismatch. Bronchodilators are the mainstay of treatment. By definition, asthma is marked by wheezing that is responsive to bronchodilators. Beta agonists such as albuterol result in the activation of sympathetic nerve receptors that act directly to stimulate bronchodilation within the smooth muscle of the bronchial tree. In contrast, ipratropium bromide works as a parasympatholytic agent that causes bronchodilation by inhibiting the typically tonic muscles that encircle the bronchi. For children in mild to moderate distress, these medications can be delivered with equal efficacy either by nebulizer or by metered-dose inhaler with an appropriate aerochamber device. Children in more severe distress may benefit from nebulizer administration earlier in the course.

Corticosteroids are the cornerstone of anti-inflammatory therapy for asthma; they are used to manage both acute and chronic episodes. The effects of corticosteroids are often not seen for approximately 4 to 6 hours, so they should be administered early in the course of an acute exacerbation of asthma. Corticosteroid use should not replace aggressive beta-2 agonist therapy, but rather should complement it. Monitoring end-tidal capnography is useful in assessing the degree of obstruction and the response to therapy (or lack thereof).

Also available to the CCTP treating a child with an asthma exacerbation are medications that act on the bronchi and their associated musculature. These medications include magnesium sulfate, epinephrine, and terbutaline. In extreme cases, Heliox can be used to deliver nebulized medications to help improve laminar flow in the distal bronchioles.

Signs and Symptoms

Asthma

- Shortness of breath
- Wheezing
- Chest tightness

Differential Diagnosis

Asthma

- Airway obstruction with a foreign body
- Bronchitis
- Pneumonia/bronchiolitis
- Cystic fibrosis
- Bronchopulmonary dysplasia (in premature infants)
- Dysmotile cilia syndrome
- Alpha-1 antitrypsin deficiency
- Heart failure
- Immunodeficiencies

Transport Management

Asthma

- Administer a bronchodilator, commonly a beta-2 agonist.
- Administer corticosteroids early in an acute exacerbation.
- Consider administering magnesium sulfate, epinephrine, and/or terbutaline.
- Consider Heliox.
- Apply noninvasive positive-pressure ventilation strategies.

Pneumonia

Pneumonia is a type of parenchymal lung disease that occurs in the lung itself and can result from viral infections, bacterial infections, or a combination of the two. While children with pneumonia frequently have focal physical exam findings such as diminished lung sounds and crackles, it can be clinically difficult to differentiate pneumonia from other etiologies such as viral pneumonitis. As such, the clinical diagnosis of pneumonia is typically confirmed by plain radiography or ultrasonography. Transport treatment includes a vigilant assessment of the patient's work of breathing and hydration status. Antibiotic therapy is frequently required and may have begun at the initial facility prior to transport.

Signs and Symptoms

Pneumonia

- Fever
- Grunting
- Cough
- Congestion
- Irritability
- Decreased feeding
- Shortness of breath
- Sweating
- Shaking and chills
- Pleurisy
- Headache
- Muscle pain
- Fatigue

Differential Diagnosis

Pneumonia

- Airway foreign body

- Bronchiectasis
- Bronchitis
- Cystic fibrosis
- Gastroesophageal reflux
- Heart failure
- Human immunodeficiency virus
- Pertussis

Transport Management

Pneumonia

- Be vigilant in assessing the child’s work of breathing and hydration status.

Acute Respiratory Distress Syndrome

The presentation of acute respiratory distress syndrome (ARDS) is similar in children and adults. Regardless of the underlying cause, the cardinal determinant of ARDS is intrapulmonary shunting that shows minimal or no response to oxygen therapy. Typically resulting from an acute pulmonary infection, sepsis, or profound exposure to a toxic irritant, ARDS is caused by the loss of surfactant, an increase in pulmonary vascular permeability, and the loss of aerated tissue. This diagnosis also includes the presence of bilateral opacities on chest imaging **FIGURE 24-21**. In addition to treating the underlying etiology, management is primarily supportive, including mechanical ventilation with the use of judicious PEEP and cardiovascular support.

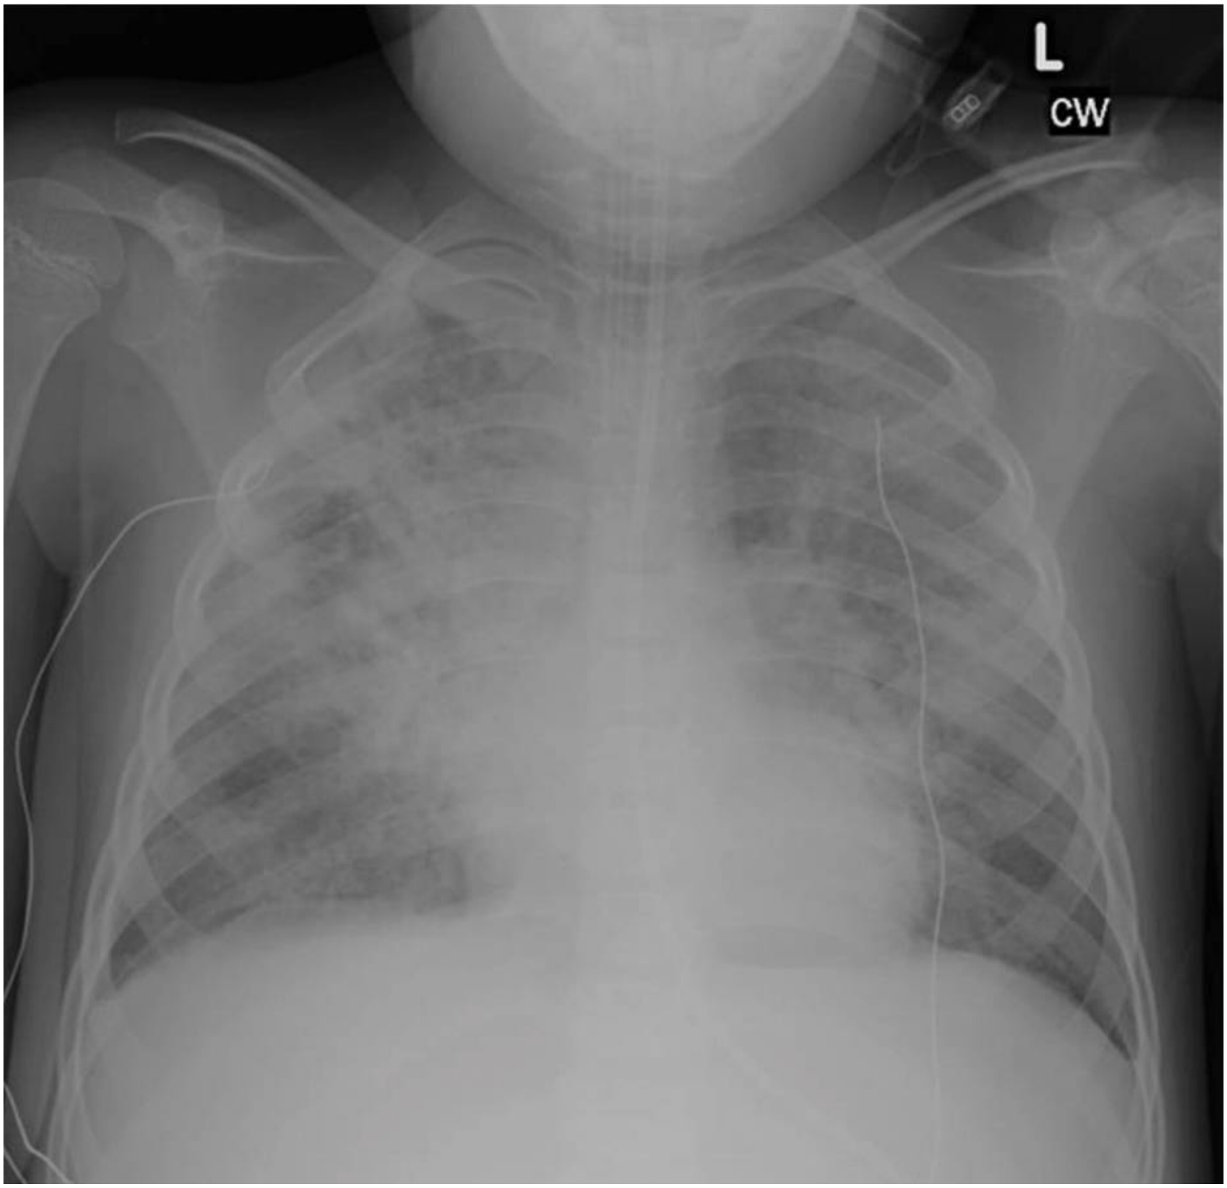

FIGURE 24-21 AP plain radiograph of the chest shows several areas of dense opacification involving multiple lung segments.

Signs and Symptoms

Acute Respiratory Distress Syndrome

- Shortness of breath
- Rapid breathing
- Cough
- Fever
- Low BP
- Confusion
- Extreme tiredness

Differential Diagnosis

Acute Respiratory Distress Syndrome

- Goodpasture syndrome
- Hypersensitivity pneumonitis
- Multisystem organ failure from sepsis
- Pneumonia
- Respiratory failure
- Bacterial sepsis
- Septic shock
- Hemorrhagic shock
- Toxic shock syndrome

Transport Management

Acute Respiratory Distress Syndrome

- Provide support, including mechanical ventilation.

Mechanical Ventilation

Noninvasive Mechanical Ventilation

Noninvasive methods of mechanical ventilation or support have become increasingly popular in recent years. As providers have recognized the resilience of pediatric physiology and the deleterious effects of ET intubation in unseasoned hands, noninvasive strategies have become commonplace in the prehospital, hospital-based, and interfacility settings. Noninvasive methods include heated high-flow nasal cannula (HHFNC), CPAP (including “bubble CPAP” for infants), BPAP, and nasal noninvasive positive-pressure ventilation (essentially BPAP with a respiratory rate). These modalities offer a therapeutic option for children with significant hypoxic or hypercapneic respiratory failure who are maintaining their airway and for whom ET intubation is not yet warranted.

HHFNC requires the use of humidified oxygen and can provide support ranging from 2 to 60 L/min. This method can ensure a fraction of inspired oxygen (F_{IO_2}) level of 0.21 to 1.00, and while it provides a small degree of PEEP, the amount is limited and varies between ventilators. Depending on the flow rate, limiting factors for providing ventilation via HHFNC are the type of ventilator available to the CCTP and the available oxygen supply. At high rates, HHFNC can quickly exhaust the oxygen supply on standard ambulances and air medical units. Providers can use mathematical equations to predict the available oxygen supply based on flow rate, transport time, and size of the oxygen tank, as discussed in Chapter 7, *Ventilation*. HHFNC requires specialized nasal prongs that are generally shorter and wider than those found on standard nasal cannula.

CPAP has become more ubiquitous in prehospital and interfacility protocols for managing respiratory distress. For patients with the ability to maintain their own airway but who require significant respiratory support, CPAP is the first in the array of noninvasive strategies available for children. This ventilation method provides pressure to continuously stent open distal airways. This effect is particularly helpful in patients with pneumonia, asthma/RAD, bronchiolitis, and other pathologies that cause distal airway collapse caused by bronchoconstriction, inflammation, or mucus burden. CCTPs can titrate both the F_{IO_2} and the flow pressure and can optimize patient oxygenation and support, to some extent, the work of breathing.

BPAP ventilation provides two levels of pressure: one during inspiration and the other during exhalation. This method provides a greater degree of ventilatory support than CPAP does. BPAP is typically triggered by a patient's respiratory effort, but a backup rate can provide a minimum number of breaths per minute. When a rate is set using BPAP, this modality is sometimes referred to as noninvasive positive-pressure ventilation.

Both CPAP and BPAP require specialized nasal prongs or face masks, which have variable degrees of tolerance by pediatric patients.

Invasive Mechanical Ventilation

The CCTP may be called upon to perform ET intubation in children who require invasive ventilation strategies. Pediatric ET intubation programs should be supported by education and clinical opportunities to manage airways in a controlled environment such as an operating room. Continuous education, supported by a robust quality improvement program, are hallmarks of high-functioning CCTP pediatric intubation programs. Skilled providers should anticipate the challenges associated with difficult airways, including the need for rescue devices and medications to facilitate rapid sequence intubation. Further, CCTPs should be familiar with different strategies for ventilating the patient, once intubated.

A target tidal volume of 7 to 10 mL/kg is recommended. Tidal volumes of less than 7 mL/kg may result in hypoventilation and atelectasis. Tidal volumes of greater than 10 mL/kg may result in overdistention of alveoli, compressing the pulmonary capillary bed and causing barotrauma.

The initial peak inspiratory pressure (PIP) should be the lowest possible value that results in adequate chest excursion. Most children should be adequately ventilated with a PIP of 20 to 30 cm H_2O, although children with lung disease may require higher PIP values—specifically, in the range of 30 to 39 cm H_2O. PIP levels greater than 40 cm H_2O increase the risk of barotrauma, especially pneumothorax. Many CCTPs will consider an alternative type of mechanical ventilator if the pediatric patient requires a PIP of more than 40 cm H_2O. **TABLE 24-7** lists age-appropriate ventilator settings.

TABLE 24-7 Age-Appropriate Ventilator Settings

Setting	Infant	Child
FIO_2	0.21–1.0	0.21–1.0
I time, s	0.5–0.8	0.6–0.8
I:E ratio	1:2 to 1:3	1:2 to 1:3
Tidal volume, mL/kg	7–10	7–10
PEEP, cm	5	5
PS, cm	5–15	5–20
Rate, breaths/min	25–30	20 (neonates: 30–50)

Abbreviations: FIO_2, fraction of inspired oxygen; I time, inspiratory time; I:E, inspiratory to expiratory; PEEP, positive end-expiratory pressure; PS, pressure support

© Jones & Bartlett Learning.

Physiologic PEEP for infants and children is 3 to 5 cm. Higher levels of PEEP may help with alveolar recruitment and improve oxygenation. Higher levels of PEEP also increase intrathoracic pressure, resulting in decreased venous return to the heart. This decreased venous return may cause hypotension in children with decreased intravascular volume status or cardiovascular instability.

PEEP levels of 8 to 12 cm H_2O increase the risk of barotrauma and spontaneous pneumothorax. Many CCTPs will consider an alternative type of mechanical ventilator if the pediatric patient requires PEEP values of greater than 12 cm H_2O.

The use of pressure support is most helpful in patients who are best ventilated with a spontaneous respiratory pattern and in patients who are being weaned from mechanical ventilation. Increasing pressure support increases the tidal volume of the patient's spontaneous breaths. This intervention may be helpful in patients who have an adequate spontaneous rate but an inadequate tidal volume. A patient with status asthmaticus, for example, generally is more effectively ventilated with a spontaneous pattern such as pressure support. The initial rate is set based on age-appropriate values and then titrated based on blood gas findings and exhaled carbon dioxide values.

In infants and children with severe lung disease, an alternative for the type of ventilator is an oscillator. An oscillator delivers smaller tidal volumes with very rapid respiratory rates (60 to 1,000 breaths/min) that reduce the risk of barotrauma and pneumothorax. The availability of an oscillator may be the reason for transporting the child to another facility.

Ventilator Setting Changes

Ventilatory strategies are aimed at optimizing oxygenation and ventilation. Consultation between the referring hospital and the intensive care team at the accepting hospital will help identify the optimal strategy for the specific patient. The CCTP may be called upon to make modifications to the ventilatory settings in response to clinical changes in the patient's condition, mainly the arterial partial pressure of oxygen and $ETCO_2$.

In pressure- and volume-cycled ventilation, increasing FIO_2, inspiratory time, and PEEP will all improve oxygenation. Increasing PIP and tidal volume within the target range will also improve oxygenation. Ventilation, as assessed by the $ETCO_2$ level, is predominantly rate driven. Increasing the respiratory rate may result in the desired decrease in retained carbon dioxide, but care must be taken when implementing this change. The expiration phase of respiration must be sufficiently long to allow gas exchange to occur. Increases in the respiratory rate above a certain threshold will result in diminished expiratory times, which may worsen ventilation.

For example, consider a patient with an inspiratory time of 0.8 second and a respiratory rate of 12 breaths/min. The total time for each breath cycle is 5 seconds. This time frame is determined by dividing 60 seconds by the rate of 12. The expiratory time is calculated by subtracting the inspiratory time from the total time for each breath cycle. In this case, 5 seconds – 0.8 second = 4.2 seconds. If the rate is increased to 15, then the total time for the breath cycle is 4 seconds. The expiratory time is now 3.2 seconds, which leaves the patient plenty of time for adequate expiration.

Now consider a patient with an inspiratory time (I) of 0.8 second and a respiratory rate of 30 breaths/min. In this case, the total time for each breath cycle is 2 seconds. The expiratory time is 2 seconds – 0.8 second = 1.2 seconds. This gives the patient an I:E ratio of 1:2. If the ventilatory rate is increased to 33, then the total time for the breath cycle is 1.8 seconds. This changes the expiratory time to 1 second, and the I:E ratio changes to 1:1.25. In this case, increasing the respiratory rate would worsen ventilation because it decreases the time available for exhaling carbon dioxide. For this patient, increasing PIP or tidal volume is a better strategy. The CCTP might also consider decreasing the rate or the inspiratory time to lengthen the time available for expiration. This strategy is particularly helpful in patients with bronchospasm, in whom elevated carbon dioxide levels might be a result of air trapping.

Cardiac Conditions

Pediatric cardiac conditions that have an effect on the circulatory system are common indications for transport. These conditions range from acquired conditions, such as hypovolemia related to trauma, to congenital conditions, such as structural heart defects (addressed later in this chapter). The CCTP will routinely be involved in care of children with four types of heart disease or conditions: a known cardiac defect, an unknown or suspected cyanotic defect (based on patient presentation), a cardiac arrhythmia, and some form of shock (cardiogenic, septic, hemorrhagic, neurogenic, or anaphylactic).

Cardiac Anomalies

Some children with congenital heart defects may need immediate medical management or surgical intervention to repair the defect. These children typically have ductal-dependent lesions, meaning they rely on the patency of the ductus arteriosus for survival, as described in this section. Survival with a good neurologic outcome depends on early recognition, the initiation of IV prostaglandin to maintain the patency of the ductus, and transport to a pediatric facility with the surgical and medical expertise to manage these lesions.

Congenital cardiac anomalies may not be diagnosed until a neonate is 1 to 2 weeks of age because the ductus arteriosus remains patent and allows adequate mixing of oxygenated and deoxygenated blood. Once the ductus closes, children with ductal-dependent lesions can present with a broad spectrum of symptoms, but often exhibit an ill appearance, pallor, and poor feeding cyanosis. These symptoms can also be seen in the setting of sepsis, trauma, and inborn errors of metabolism, which may delay the diagnosis of complex congenital heart disease. In a neonate who has a relatively small lesion and a more subtle presentation, diagnosis of such an anomaly may not be made until the child reaches 2 to 8 weeks of age, when the characteristic murmur may be heard or when the child develops signs of heart failure.

The development of both palliative and curative surgical approaches has created generations of patients (both young and old) with complex repairs that include artificial shunts, single-ventricle pathology, and support from continuous medications such as milrinone and technology such as left ventricular assist devices. The depth of knowledge needed to manage these children exceeds the scope of this text. The CCTP should consult with medical control and accepting subspecialists to identify those complications that may be encountered or anticipated during interfacility transport of these medically fragile patients.

Acquired anatomic diseases are not as common as they once were. In recent years, incidence of cardiac disease related to rheumatic fever (ie, mitral valve disease) and Kawasaki disease (ie, coronary artery aneurysms) has declined.

Pediatric ECG Interpretation

The interpretation of an ECG rhythm in children differs from that in adults. To decrease the amount of respiratory artifact, it is helpful to avoid placing the ECG leads at the level of the diaphragm. Specifically, the leads may be placed on the lower abdomen or on the pediatric patient’s thighs. A 12-lead ECG is not as commonly used in children but may be obtained for children with abnormal findings on the rhythm strip, arrhythmias, congenital heart disease, acquired heart disease, chest trauma, or suspected cardiotoxic ingestions **FIGURE 24-22**.

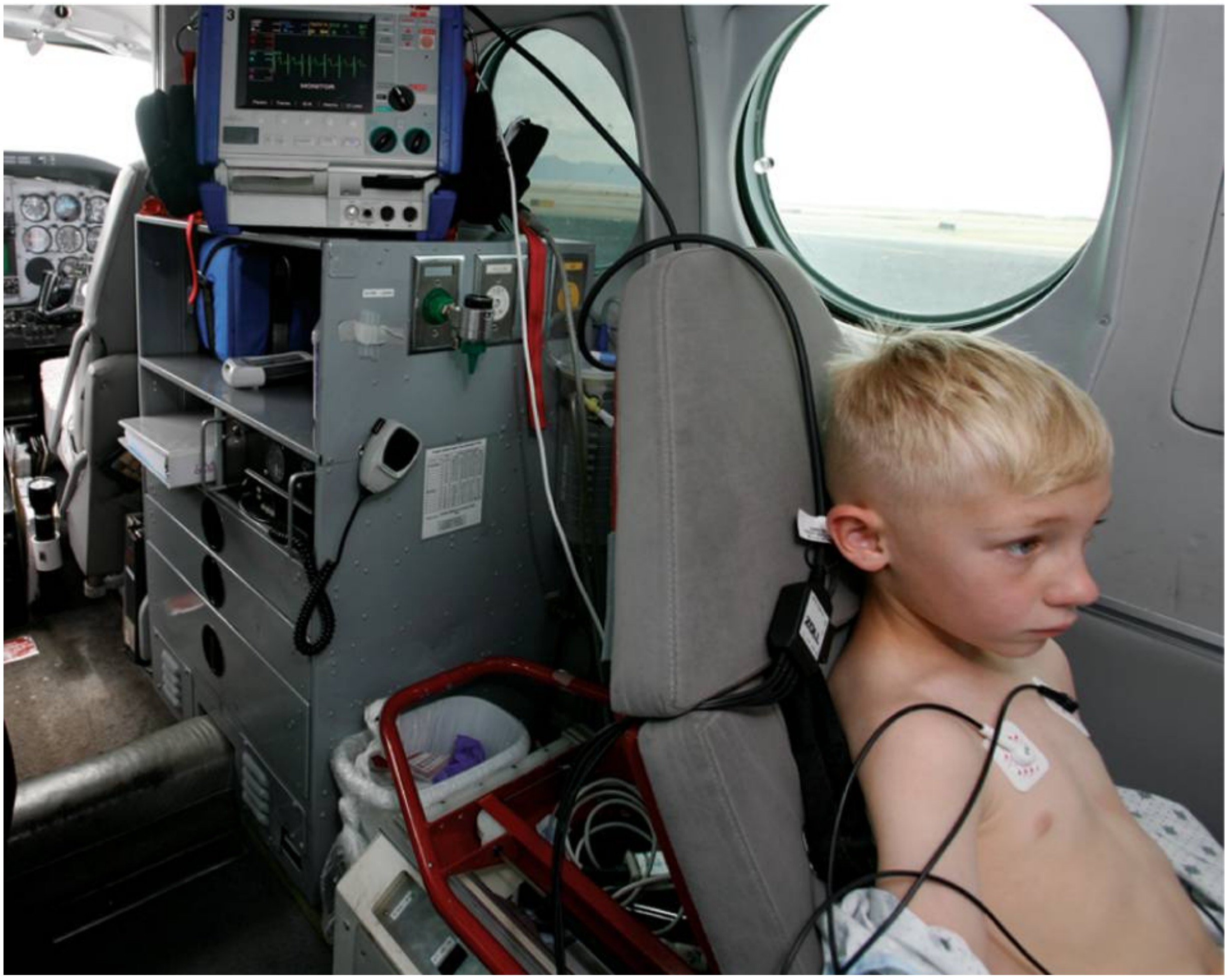

FIGURE 24-22 A pediatric critical care transport patient with ECG leads placed. A 12-lead ECG is not as commonly used in children as it is in adults.

© Jones & Bartlett Learning.

The first aspect of rhythm strip interpretation is assessing whether the rate is appropriate for the child's age. The next step is evaluating the components of the rhythm, including the PR interval and the width of the QRS complex. Normal values for these components vary with age. A general guideline for children is that the PR interval should be 0.16 second or less and the QRS complex should be 0.08 second or less. A PR interval of greater than 0.20 second indicates a first-degree heart block. A QRS complex of greater than 0.08 second indicates a wide complex arrhythmia.

In patients with tachyarrhythmia, it may be helpful to increase the ECG monitor sweep speed (typically 25 mm/s) to assess for the presence of a P wave. By increasing the ECG monitor sweep speed, the CCTP can identify subtle nuances in the components of the ECG (P, QRS, T wave).

Pediatric Arrhythmias

Similar to adults, pediatric patients can have both bradyarrhythmias and tachyarrhythmias. Bradyarrhythmias are uncommon in neonates and young children. First-degree heart block is sometimes identified incidentally during the evaluation of complaints such as syncope or chest pain. As in adults, first-degree heart block in children is of little clinical consequence. Symptomatic bradycardia should raise the suspicion for sepsis, myocarditis, Lyme disease, or poisoning. Third-degree heart block has occasionally been identified in patients with Lyme carditis and infrequently in neonates born to mothers with systemic lupus erythematosus. Symptomatic children should be treated in accordance with the AHA guidelines for pediatric advanced life support.

Narrow complex tachycardias, typically supraventricular tachycardias, are more frequently encountered in children. While school-age children and adolescents may present with the more prototypical story of palpitations, younger children and infants frequently present with nondescript symptoms such as fussiness or poor eating. As young children can tolerate tachyarrhythmias longer than adults can, they may present later and often do so with signs of heart failure. Ventricular tachyarrhythmias are uncommon in children, except those with a history of cardiac surgery. A child who experiences a cardiac arrest from a ventricular arrhythmia may have familial disorders of electrolyte transport, otherwise known as channelopathies. Long QT syndrome can also precipitate torsades de pointes and other ventricular arrhythmias, although this scenario is uncommon in children.

The CCTP should be familiar with the range of normal heart rates in children. Misunderstanding what is normal for a given age group is a frequent contributor to errors in diagnosing tachyarrhythmias.

Cardiac Arrest and Death During Interfacility Transport

Cardiac arrest during pediatric interfacility transport is uncommon; nonetheless, discussion with the referring and receiving physicians may identify patients at highest risk for cardiac arrest. This consultation might lead providers to change the mode of transportation. For example, performing compressions in a helicopter is more challenging than in a ground ambulance. In children who have experienced cardiac arrest prior to transport, the CCT team should discuss both anticipated medical challenges and goals of care.

In the event of cardiac arrest during ground transport, providers should stop the ambulance in a safe location to safely facilitate high-quality cardiopulmonary resuscitation. If resuscitation does not rapidly result in return of spontaneous circulation, providers should follow preestablished agency policies that direct the ambulance to the closest hospital. Likewise, if cardiac arrest occurs during air medical transfer, all attempts should be made to resuscitate the patient prior to landing. Agencies offering helicopter or fixed-wing transport should develop contingency plans for these events; these plans should designate, among other considerations, available airports and landing zones, and the resources available to intercept the patient for transfer to a hospital.

Advance Directives for Pediatric Patients

Although less common in pediatric patients than in adults, children with complex and long-standing medical problems that are known to be life limiting may have an advance directive; the CCT team will need to ascertain this information from the referring facility.

Shock

Shock is a state of poor perfusion and can result from various precipitating events. Due to their unique physiology, children will manifest the signs and symptoms of shock differently than adults do. The CCTP must understand these differences to recognize shock in a sick child and to intervene appropriately.

Shock is broadly categorized as compensated or uncompensated. A child in early or even moderate stages of shock is able to maintain perfusion. Because children typically have strong cardiovascular systems, they are able to compensate for inadequate perfusion by increasing the pulse rate and peripheral vascular resistance more efficiently than adults can. Hypotension is, therefore, a late and ominous sign in an infant or a young child, and urgent intervention is needed to prevent cardiac arrest. As a result, BP should not be the only parameter that the CCTP uses to assess for shock. Other indicators, such as the child's LOC, heart rate, skin temperature, respiratory rate and pattern, capillary refill time, and urinary output, are also valid markers of hemodynamic stability and fluid status.

Signs and Symptoms

Shock

- Light-headedness
- Tachycardia
- Decreasing BP
- Confusion or loss of consciousness (coma)
- Chest pain
- Diarrhea
- Kidney failure
- Pale, clammy skin

Transport Management

Shock

- Assess airway, breathing, and circulation.
- Attempt to control obvious bleeding with direct pressure.
- Obtain a finger-stick blood glucose level to ensure hypoglycemia is not present.

- Administer oxygen.
- Administer IV fluids and medications per protocols.

Hypovolemic Shock

Hypovolemic shock is the most common cause of shock in pediatric populations and is characterized by inadequate intravascular volume. Young children experiencing respiratory illnesses tend to eat and drink less. Given their relatively poor fluid reserves, as compared to adults, they are susceptible to severe dehydration. Dehydration is marked clinically by poor urine output. Coupled with vomiting and/or diarrhea, the volumes of which are difficult to quantify, severe dehydration can insidiously lead to hypovolemic shock in children.

Volume loss related to blood in children is most commonly associated with trauma. Another form of fluid loss is excessive urination, like that seen in children with diabetes. Finally, shock resulting from severe allergic reactions may be related to increased capillary permeability that results in third spacing, as well as to distributive shock states that result in decreased peripheral vascular tone.

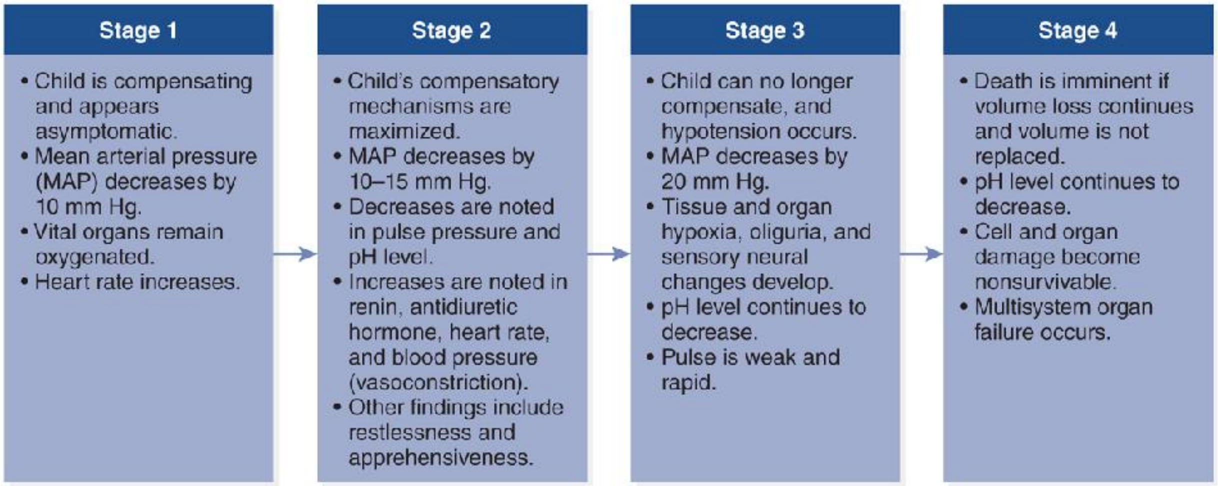
When intravascular volume falls, there is inadequate venous return and decreased cardiac output. Cardiac output is a primary factor in end-organ perfusion. Inadequate volume may be related to a deficit in the circulating fluid volume, resulting in insufficient volume for perfusion.

Hypovolemic shock is categorized into four stages **FIGURE 24-23**:

- Stage 1: The child appears asymptomatic.
- Stage 2: The child attempts to accommodate for volume losses but compensatory mechanisms are being maximized. BP may still be compensated at this time, but the child is dangerously close to decompensating if interventions are not rapidly applied.
- Stage 3: The child is no longer able to compensate and hypotension occurs. In addition to traditional signs of shock, the child demonstrates mental status changes and significantly

decreased urine output. Many children require blood transfusions at this point for resuscitation to be successful.

- Stage 4: Death is imminent without cessation of the volume loss and aggressive volume replacement, including crystalloids and blood products.



Stage 1

- Child is compensating and appears asymptomatic.
- Mean arterial pressure (MAP) decreases by 10 mm Hg.
- Vital organs remain oxygenated.
- Heart rate increases.

Stage 2

- Child's compensatory mechanisms are maximized.
- MAP decreases by 10–15 mm Hg.
- Decreases are noted in pulse pressure and pH level.
- Increases are noted in renin, antidiuretic hormone, heart rate, and blood pressure (vasoconstriction).
- Other findings include restlessness and apprehensiveness.

Stage 3

- Child can no longer compensate, and hypotension occurs.
- MAP decreases by 20 mm Hg.
- Tissue and organ hypoxia, oliguria, and sensory neural changes develop.
- pH level continues to decrease.
- Pulse is weak and rapid.

Stage 4

- Death is imminent if volume loss continues and volume is not replaced.
- pH level continues to decrease.
- Cell and organ damage become nonsurvivable.
- Multisystem organ failure occurs.

FIGURE 24-23 Progression of hypovolemic shock.

Abbreviation: ADH, antidiuretic hormone

Description

Regardless of the etiology of the volume loss, the principles of resuscitation for patients are identical:

1. Stop the source of volume loss, whether it involves bleeding, vomiting and diarrhea, or vasodilation.
2. Replace the volume loss. Fluid resuscitation for children consists of 20 mL/kg of crystalloid solutions. Fluid boluses of crystalloid solution may be repeated up to three times for a total of 60 mL/kg. If losses are ongoing, such as occurs in severe gastroenteritis (ie, cholera), the child should continue to receive replacement fluids. If a child has a cardiac history or concurrent cardiogenic shock, fluid boluses should be administered at a rate of 10 mL/kg. Ultimately, the child may receive up to three boluses of 20 mL/kg but in

smaller increments. Children with volume loss related to trauma will benefit from early administration of blood products, including packed red blood cells, fresh frozen plasma, and platelets. Often blood products are preceded by 40 mL/kg of crystalloid fluids. Caution should be taken with continued administration of crystalloid fluids, as emerging evidence indicates that these fluids may precipitate coagulopathy in severely injured children.

Transport Management

Hypovolemic Shock

- Stop the source of volume loss (ie, bleeding, vomiting, diarrhea, and vasodilation).
- Replace the volume loss with fluid boluses and blood products.

Successful resuscitation is measured by a return to a normal heart rate, respiratory rate, BP, improved mental status, and improved skin condition.

Cardiogenic Shock

Causes of cardiogenic shock include, but are not limited to, congenital cardiac defects, drug toxicity, metabolic causes, hypovolemia, myocarditis, and arrhythmias. Congenital defects are much more likely to be the cause of cardiogenic shock compared to the other etiologies. The child with cardiogenic shock will present with traditional signs of shock, including tachycardia, tachypnea, hypoxia, mental status changes, and changes in skin condition. Such a patient also often presents with pulmonary congestion resulting in crackles heard on auscultation and jugular venous distention. A chest radiograph may reveal cardiomegaly.

Treatment principles concentrate on improving cardiac function with fluid resuscitation and inotropic support, to include dopamine, dobutamine, epinephrine, milrinone, and norepinephrine. Primary pathologies or impedances are treated, and cardiac function may be supported pharmacologically until myocardial function returns.

Signs and Symptoms

Cardiogenic Shock

- Traditional signs of shock, including tachycardia, tachypnea, hypoxia, mental status changes, and changes in skin condition
- Pulmonary congestion resulting in crackles heard on auscultation
- Jugular venous distention

Transport Management

Cardiogenic Shock

- Resuscitate with fluids if needed to ensure normovolemia.
- Provide inotropic support, including dopamine, dobutamine, epinephrine, milrinone, and norepinephrine.
- Treat primary pathologies or impedances.
- Support cardiac function pharmacologically until myocardial function returns.

Distributive Shock

The major treatment goals for **distributive shock** include stopping the vasodilation, returning volume to the intravascular space, and improving tissue perfusion. Types of distributive shock include neurogenic shock, anaphylactic shock, and septic shock.

Neurogenic Shock

Neurogenic shock, also known as spinal shock, often presents with significant hypotension without tachycardia due to the loss of spinal cord–mediated vascular tone. Treatment for neurogenic shock may include administration of vasoactive medications; however, volume replacement with crystalloids must occur first. The principle of “fill the tank first and then make the container smaller” is the cornerstone of treatment. Neurogenic shock may respond to norepinephrine.

Transport Management

Neurogenic Shock

- Replace volume with crystalloids.
- Administer vasoactive medications.

Anaphylactic Shock

Children in **anaphylactic shock** often present with increased general body edema, hypotension, rash, urticaria, anxiety, and warm, flushed skin. Bronchospasm and laryngeal edema may also be life threatening.

Management of anaphylactic shock involves removal of the allergen, volume replacement, and epinephrine. Epinephrine dilates the bronchioles, relaxes the smooth muscle, causes vasoconstriction, and decreases vascular permeability, thereby inhibiting more volume loss. Adjuncts such as antihistamines (ie, diphenhydramine) and corticosteroids are controversial, though their use remains common practice.

Systemic Inflammatory Response Syndrome and Septic Shock

Systemic inflammatory response syndrome (SIRS) and **sepsis** are both distributive shock syndromes characterized by inflammation, vasodilation, significantly increased microvascular permeability, and accumulation of leukocytes resulting in hypoperfusion and end-organ dysfunction. Early recognition and aggressive resuscitation are key to good outcomes with these conditions.

Signs and Symptoms

Anaphylactic Shock

- General body edema
- Hypotension
- Rash
- Urticaria
- Anxiety
- Warm, flushed skin

- Bronchospasm
- Laryngeal edema

Transport Management

Anaphylactic Shock

- Remove the allergen.
- Replace fluid volume loss.
- Administer epinephrine.

As in adults, SIRS in pediatric patients is an inflammatory response that may result from injury (trauma) or infection. Hallmarks of SIRS are altered thermoregulation (hyperthermia or hypothermia), tachycardia, tachypnea, and age-specific alterations in white blood cells (WBCs). WBCs may be increased (usually a WBC count greater than 20,000/mm^3 is indicative of infection) or decreased (a WBC count less than 4,000/mm^3, referred to as *leukopenia*, is most often due to low numbers of neutrophils, a condition called **neutropenia**). In addition, **bandemia** is often present, meaning that certain bands of immature WBCs are released into the bloodstream in excess (more than 10% of the total WBC population).

Sepsis is SIRS that occurs in tandem with a known or suspected infection. Normally, the body has a balanced immune response to infection, mounting an immune assault that results in elimination of the pathogens and full recovery. In some instances, however, the immune system becomes exhausted during the usual response, leading to impaired immunity. If the pathogens were contained prior to the onset of impairment, secondary infection may ensue, leading to increased morbidity or mortality. If the pathogens were not contained, morbidity or mortality may result from the primary infection. Alternatively, for reasons that remain poorly understood, excessive inflammation or SIRS can occur, the consequences of which are potentially more injurious than the original insult. Early and targeted antibiotic therapy should be initiated to combat the suspected infectious agent. Some evidence indicates that early and judicious administration of fluids reduces morbidity and mortality related to sepsis.

Renal Conditions

Acute kidney injury (AKI) is defined as profound deterioration of renal function associated with increasing levels of solute (BUN or creatinine). Actual urine volume in such cases can vary from normal urine output to oliguria. Causes of AKI are generally divided into three categories **TABLE 24-8**:

- **Prerenal acute kidney injury** is caused by decreased perfusion of an intact nephron.
- **Intrarenal acute kidney injury** is caused by damage of an actual nephron.
- **Postrenal acute kidney injury** is caused by downstream obstruction with initially intact nephrons.

TABLE 24-8 Common Causes of Acute Kidney Injury

Type of Failure	Causes	Example
Prerenal (decreased perfusion of an intact nephron)	Hypovolemia	Hemorrhagic shock Dehydration (gastrointestinal losses and diabetic ketoacidosis) Insensible losses (prematurity, burns) Sodium and water losses (renal, adrenal, endocrine) Hypoproteinemia
	Hypotension	Heart failure Decompensated shock Congenital heart disease
	Renal vessel injury with obstruction	Not applicable

Type of Failure	Causes	Example
Intrarenal (damage of the actual nephron)	Primary parenchymal disease	Hemolytic uremic syndrome Post-strep (acute) Glomerulonephritis Lupus erythematosus Henoch-Schönlein purpura Pyelonephritis Malignant hypertension
	Acute tubular necrosis	Ischemia (prolonged prerenal acute kidney injury) Nephrotoxins (heavy metals, uric acid, nonsteroidal anti-inflammatory drugs, angiotensin-converting enzyme inhibitors, aminoglycoside antibiotics, beta blockers, diuretics, radiocontrast, myoglobin, organic solvents)
	Large-vessel occlusion	Renal vein thrombosis Renal artery stenosis Thrombosis or emboli
	Congenital abnormalities	Renal agenesis Infantile polycystic kidney disease Bilateral multicystic kidneys
	Neoplasm	Not applicable
Postrenal (downstream obstruction with initially intact nephrons)	Obstructive uropathy	Posterior urethral valves Prune belly syndrome Neurogenic bladder Ureteropelvic junction syndrome Tumor Nephrolithiasis Renal calculi Trauma to the collecting system Ureterocele

© Jones & Bartlett Learning.

Prerenal Disorders

Prerenal causes of AKI are the most common in children and are primarily related to dehydration and decreased renal perfusion.

Dehydration results from fluid loss or acute blood loss. The patient may present with a range of signs and symptoms—nausea, vomiting, diarrhea, diabetic ketoacidosis, all forms of shock, and burns. A decreased circulating blood volume results in decreased renal perfusion.

Other causes of decreased renal perfusion may be related to any cardiac condition that results in decreased cardiac output, such as heart failure. In patients with sepsis or burns, there may actually be sufficient or increased extracellular fluid volume as a result of increased vascular permeability, but the intravascular volume is greatly depleted. AKI from volume loss is frequently corrected with volume resuscitation.

Intrarenal Disorders

Intrarenal or parenchymal causes of AKI are diverse; all of these etiologies, however, lead to nephron damage and loss of glomerular function as a result of damage to the glomerular basement membrane. Damage to the arterioles and glomerular capillaries may be the result of coagulation, inflammation, barotrauma, or prolonged ischemia.

The proximal tubular cells of the kidneys have high metabolic demands, which render them more susceptible to ischemic insults. Nephrotoxins cause sloughing and necrosis of cells in the proximal tubule and ascending loop of Henle, which results in obstruction of tubular blood flow and leakage of fluid into the peritubular space and plasma.

Occlusion of the renal arteries from emboli or thrombosis may cause infarction as a result of decreased renal blood flow. Vascular congestion and hemorrhagic necrosis may also occur as a result of renal vein thrombosis.

Hemolytic Uremic Syndrome

Hemolytic uremic syndrome (HUS) is one of the major causes of AKI in infants and children younger than 4 years. Its hallmarks include the classic triad of microangiopathic hemolytic anemia, thrombocytopenia, and acute injury to the kidney. Classification of HUS has traditionally been divided into diarrhea-positive and diarrhea-negative forms. Diarrhea-positive HUS is caused by Shiga toxin–producing *Escherichia coli* (STEC) infections, which are responsible for 90% of HUS cases and typically affect children 5 years or younger, and occasionally by *Shigella dysenteriae* type 1 infection. All other types of HUS are considered atypical and labeled as diarrhea-negative HUS.

The primary pathology in HUS is thought to be related to endothelial cell injury in the renal cortex that leads to localized vascular coagulation and fibrin deposits. As the red blood cells (RBCs) pass through the fibrin strands in the renal vasculature, they become fractured and cause microangiopathic anemia. Thrombocytopenia is the result of localized intravascular coagulation-consuming platelets.

The presentation of HUS typically follows a gastroenteritis-type illness, with symptoms including vomiting, abdominal pain, and bloody diarrhea. As the gastrointestinal symptoms subside, the child again becomes acutely ill, presenting with irritability, pallor, and a petechial rash. This presentation is often, but not always, accompanied by signs of fluid overload including peripheral edema, pulmonary edema, and hypertension.

Laboratory studies show fragmented RBCs, thrombocytopenia, and evidence of AKI, including elevated BUN and creatinine levels, hyperkalemia, and metabolic acidosis. Urine studies show proteinuria and hematuria with or without anuria.

Treatment of HUS is primarily supportive and includes fluid and metabolic balance, control of hypertension (treatment of DBP greater than 120 mm Hg with labetalol, nifedipine, or hydralazine), transfusion of packed RBCs and platelets if required, and aggressive treatment of AKI with possible dialysis or continuous renal replacement therapy (CRRT) when the BUN exceeds 80 mg/dL. The prognosis is usually excellent when aggressive treatment is initiated early.

Signs and Symptoms

Hemolytic Uremic Syndrome

- Gastroenteritis-type symptoms: vomiting, abdominal pain, and bloody diarrhea
- After the gastrointestinal symptoms subside: irritability, pallor, signs of fluid overload, including peripheral and pulmonary edema, hypertension, and petechiae

Transport Management

Hemolytic Uremic Syndrome

- Support fluid and metabolic balance.
- Control hypertension.
- Transfuse packed RBCs and platelets if required.

Acute Glomerulonephritis

Acute glomerulonephritis (AGN) is a histopathologic diagnosis that is associated with edema, hypertension, and hematuria. AGN results from the deposition of circulating immune complexes in the kidney basement membrane, which ultimately reduces the glomerular filtration rate. This syndrome can be induced by infection with a variety of organisms, but especially group A beta hemolytic streptococci.

Acute postinfectious glomerulonephritis (APIGN) or AGN following an acute infection can occur after a skin infection or a pharyngeal infection. Most typically caused by infection with group A *Streptococcus*, APIGN occurs most commonly in school-age children and more frequently in boys than in girls. Its pathology is thought to involve activation of the complement pathway leading to inflammation, which then causes glomerular damage through immune complex deposition in the basement membrane of the glomeruli.

Symptoms of APIGN typically manifest 1 to 2 weeks after infection, with a classic symptom being gross hematuria with brown urine. The severity of presentation runs the spectrum from mild and not requiring hospitalization, to severe oliguria with symptoms of overload including heart failure, peripheral and pulmonary edema, and hypertension.

Laboratory urinalysis values in patients with APIGN reveal RBCs and proteinuria. WBCs represent glomerular inflammation in such cases, rather than pyelonephritis (inflammation of the kidney linings). In addition, expected evidence of renal insufficiency includes elevated BUN and creatinine levels, hyperkalemia, hyponatremia, and acidosis. Elevated antibody titers (ie, measurements of the presence and amount of antibodies in the blood) of streptococci confirm APIGN after streptococcal infection.

Treatment of severe APIGN is primarily supportive and includes fluid restriction of IV solutions to avoid promoting peripheral and pulmonary edema. Loop diuretics are useful in treating mild hypertension, edema, and fluid overload. The prognosis is good, and full recovery is expected in more than 98% of all children.

Signs and Symptoms

Acute Postinfectious Glomerulonephritis

- Gross hematuria with brown urine
- Heart failure
- Peripheral and pulmonary edema
- Hypertension

Transport Management

Acute Postinfectious Glomerulonephritis

- Restrict fluids.
- Administer loop diuretics.

Acute Tubular Necrosis

Acute tubular necrosis (ATN) is a condition that results in damage to the tissue of the kidneys’ tubules. Like most renal pathologies, it can have numerous etiologies; however, the most common cause is renal ischemia precipitated by severe hypovolemia. Tubular damage can also occur following a toxic insult, such as heavy metal poisoning, or as a result of myoglobin or hemoglobin accumulation in the tubules following a severe crush injury, burn, or hemolytic crisis.

In patients with ATN, the renal tubular cells die when they do not get enough oxygen or if they are exposed to a toxic drug. Injury to the tubular cells is most prominent in the straight portion of the proximal tubules and in the loop of Henle. In addition to decreased filtration being noted, a buildup of casts and debris obstructs the tubule lumen, such that filtrate leaks through the damaged epithelium. In addition, decreased perfusion leads to diminished production of vasodilators such as nitric oxide, resulting in further vasoconstriction and hypoperfusion.

ATN is clinically defined as proceeding in three phases:

- *Phase 1: oliguric phase.* Severe oliguria lasts approximately 10 days. Renal recovery from ATN is highly unlikely if the oliguria or anuria persists longer than 3 to 6 weeks.
- *Phase 2: diuretic phase.* Passage of large volumes of isothenuric urine containing sodium levels of 80 to 150 mEq/L occurs.
- *Phase 3: recovery phase.* Signs and symptoms resolve rapidly as a result of regeneration of tubular epithelial cells, although polyuria may be present for days to weeks. The mechanism of this diuresis is not completely understood.

Signs and Symptoms

Acute Tubular Necrosis

- Severe oliguria lasting approximately 10 days
- Diuretic phase: passage of large volumes of isothenuric urine
- Recovery phase: signs and symptoms resolve rapidly
- Polyuria

Transport Management

Acute Tubular Necrosis

- Replace fluids and electrolytes.

Transport treatment usually consists of fluid and electrolyte replacement. Ultimately, dialysis is required to remove the toxins.

Postrenal Disorders

Postrenal or obstructive failure has numerous etiologies. In most cases, unilateral obstructive abnormalities do not result in AKI. Flank or abdominal pain is often present. Prolonged, unrelieved obstruction causes irreversible parenchymal damage because of infection and increased hydrostatic pressure. Obstruction of urine outflow in the renal system causes an increase in hydrostatic pressure at the proximal tubule and glomerulus, resulting in a decrease in glomerular filtration and renal function. Large nephrolithiases (renal stones), anatomic abnormalities, or obstruction from malignancy can all lead to postrenal disorder.

Complications of AKI

Several potentially life-threatening events can occur in patients experiencing AKI.

Electrolyte Imbalances

Electrolyte imbalances such as hyponatremia, hypocalcemia, and hyperkalemia may occur in patients with AKI.

Hyponatremia is most often dilutional (low sodium levels as a result of excessive fluid intake) secondary to volume overload, is asymptomatic, and is simply treated with fluid restrictions. Severe hyponatremia may cause seizures and is managed by infusing a hypertonic (3%) saline solution.

Hypocalcemia is caused by hyperphosphatemia and is not usually treated unless symptoms such as tetany, seizures, or decreased cardiac contractility are present. Rapid correction of hypocalcemia may result in the deposition of calcium salts in body tissues. Treatment includes oral dosing of calcium carbonate or, in emergent cases, cautious administration of IV calcium gluconate (10%) at a dose of 50 to 100 mg/kg. Hypocalcemia can manifest clinically with a prolonged QRS complex on ECG.

Hyperkalemia has the potential to cause life-threatening arrhythmias by producing membrane excitability. ECG changes may include peaked T waves, widened QRS complexes, and eventually bradycardia. An elevated serum potassium level is treated based on lab values and the presence of ECG abnormalities. Management may include careful monitoring, the removal of potassium chloride from IV fluids, pharmacologic treatments, and, in rare circumstances, dialysis. The following medications may be administered:

- Sodium polystyrene sulfonate resin: This ion-exchange resin acts in the colon or ileum. Usual dosing is 1 g/kg every 2 to 4 hours, and the medication may be mixed with sorbitol. Recent studies suggest this medication may be of questionable benefit.
- Calcium gluconate: This drug has no direct effect on the serum potassium but stabilizes the myocardial membrane and ventricular rhythm by changing the cell’s action potential. When it is administered, the CCTP should monitor the patient’s heart rate and stop the infusion if the child’s pulse rate drops by more than 20 beats/min. In patients with cardiac arrest secondary to hyperkalemia, the CCTP should substitute calcium chloride.
- Glucose and insulin: Potassium can be moved into the intracellular space by administering insulin (usually by infusion) with a glucose infusion of 5% dextrose in water or 5% dextrose and normal saline and a concurrent insulin infusion. The goal is to maintain the glucose level between 120 and 300 mg/dL. This has the effect of rapidly lowering the serum potassium level;

however, careful assessment of glucose blood levels is necessary to prevent hypoglycemia.

- Sodium bicarbonate: This drug can be used even in the absence of acidosis. Calcium gluconate is not compatible with $NaHCO_3$, however, so IV lines must be flushed prior to administering this medication.
- Albuterol: Massive doses of nebulized albuterol cause a shift of extracellular potassium into the cell and can lower the serum potassium by 1.0 to 1.5 mEq/L. Albuterol also helps to protect against insulin-induced hypoglycemia.

Hypertension and Hypertensive Encephalopathy

Hypertension that may progress to hypertensive encephalopathy is also a life-threatening complication in patients with AKI. Hypertension is usually caused by sodium and water retention. Hypertensive encephalopathy is hypertension associated with neurologic symptoms such as nausea, vomiting, headache, visual changes, seizures, and mental status changes. As with any hypertensive crisis, it is important to aim for a MAP reduction of 15% to 25%. A more precipitous or pronounced drop in MAP that returns the child to normal BP parameters may lead to hypoperfusion of the end organs.

Meningitis

The presentation of the pediatric patient with meningitis depends largely on the child’s age, the type of infectious organism, and the child’s current health. Bacterial meningitis is uncommon, especially among children who are fully vaccinated against this disease. The onset of symptoms is typically abrupt, with hallmark signs including fever, chills, nuchal rigidity, vomiting, photophobia, headache, back pain, and seizures in older children. Infants and young children may present with some of the same symptoms as are noted in older children, but also may experience poor feeding, marked irritability and agitation, and a characteristic high-pitched cry with bulging fontanelles.

Viral meningitis is more common than bacterial or fungal meningitis. Fungal meningitis occurs only in immunocompromised patients or in geographic areas where such infections are endemic. In young children, viruses such as enterovirus are a common cause of viral meningitis. In young infants, the toxic-appearing infant with meningitis may have an infection with herpesvirus. If unrecognized, meningitis caused by herpesvirus is frequently fatal. Bacterial meningitis in young infants can result from infections from group B *Streptococcus*, *E coli* (as the result of urosepsis/bacteremia), or, infrequently, *Listeria*. Infection with the *Neisseria meningitidis* bacterium is exceedingly rare, and vaccinations for serogroups A and B are ubiquitous around the world.

On arrival to the patient’s bedside, the CCTP may inquire whether the patient with meningitis has a positive **Brudzinski sign** or **Kernig sign**. To test for the Brudzinski sign, the patient lies supine and the examiner flexes their head and neck in an attempt to touch the chin to the chest. An abnormal response includes flexion of the legs and hips during this process (positive Brudzinski sign). Testing for this condition should not be performed if a cervical spine injury is suspected. To evaluate for the Kernig sign, the patient lies supine with the legs flexed at the hip and the knees flexed at a right angle; the CCTP then tries to extend the knees. An abnormal response is present if there is pain and resistance to knee straightening (positive Kernig sign). If pain and resistance are present bilaterally, then meningeal irritation is likely present.

The neonate patient with meningitis may be extremely difficult to assess; moreover, it is difficult to make the diagnosis of meningococcal infection in a neonate because the symptoms are usually vague in nature and challenging to differentiate from other septic etiologies. The CCTP should inquire about the infant's feeding and sucking ability. The infant with meningitis may also present with a poor cry, decreased muscle tone, jaundice, weight loss, hypothermia, apnea, cyanosis, and seizure activity.

Signs and Symptoms

Meningococcal Infections

- Fever
- Chills
- Nuchal rigidity
- Vomiting
- Photophobia
- Headache
- Back pain
- Seizures

Infants and Young Children

- Poor feeding
- Marked irritability and agitation
- Characteristic high-pitched cry with bulging fontanelles
- Poor cry
- Decreased muscle tone
- Jaundice
- Weight loss
- Hypothermia
- Apnea
- Cyanosis

- Seizure activity

Transport Management

Meningococcal Infections

- Ensure standard universal precautions are followed.

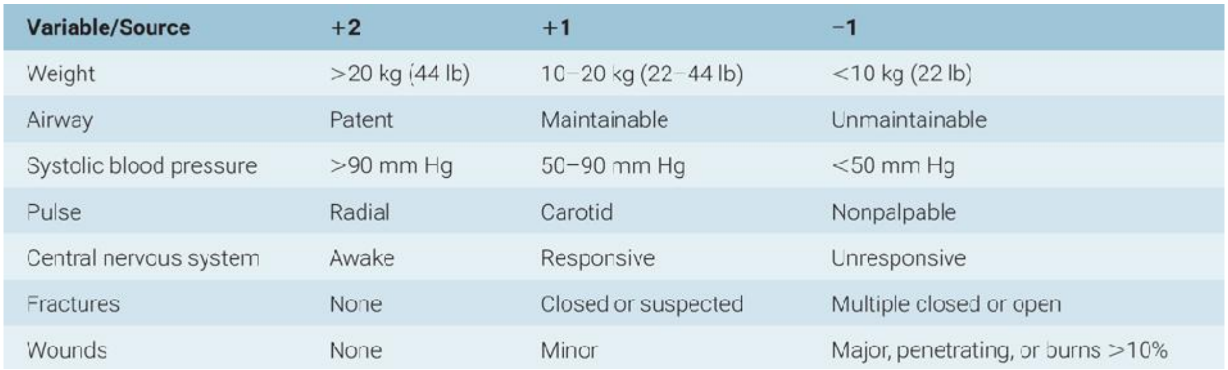
Standard universal precautions should be taken with all pediatric patients with suspected meningitis, considering the close proximity of the patient to the transport provider.

Trauma

In the United States, trauma is the leading cause of death among pediatric patients 1 year or older. Traumatic injuries in children most commonly involve motor vehicle crashes, suffocation, submersion, burns, falls, and violence. While assessment and care of pediatric trauma patients employ the same systematic approach taken for the adult population, one assessment tool, the GCS, is modified for pediatric patients. As described earlier in this chapter, the GCS can be used to assess neurologic status. This dynamic evaluation should be repeated to note changes or trends in the acutely injured child. Recent research supports the evaluation of the modified motor score in particular as a marker for acuity and for neurologic prognostication.

Another important assessment tool for the child with traumatic injury is the pediatric trauma score. Providers combine the scores for several components—weight, airway status, central nervous system status, systolic BP, pulse rate, fractures, and wounds—to arrive at a total score reflective of injury severity **TABLE 24-9**. Scores are categorized as follows:

TABLE 24-9 **Pediatric Trauma Score**



Variable/Source	+2	+1	−1
Weight	>20 kg (44 lb)	10−20 kg (22−44 lb)	<10 kg (22 lb)
Airway	Patent	Maintainable	Unmaintainable
Systolic blood pressure	>90 mm Hg	50−90 mm Hg	<50 mm Hg
Pulse	Radial	Carotid	Nonpalpable
Central nervous system	Awake	Responsive	Unresponsive
Fractures	None	Closed or suspected	Multiple closed or open
Wounds	None	Minor	Major, penetrating, or burns >10%

Reprinted from Tepas JJ III, Mollitt DL, Talbert JL, Bryant M. The pediatric trauma score as a predictor of injury severity in the injured child. *J Pediatr Surg*. 1987;22(1):14-18. Copyright © 1987, with permission from Elsevier. http://www.sciencedirect.com/science/journal/00223468.

Description

- A score of 9 to 12 indicates minor trauma. Follow local guidelines/protocols for treatment.
- A score of 6 to 8 indicates a potentially life-threatening condition. Consider transporting the patient to a trauma center.
- A score of 0 to 5 indicates a life-threatening condition. Transport the patient to a trauma center.
- A score of less than 0 indicates a condition that is usually fatal. Transport the patient to the nearest trauma center equipped to care for critically ill children.

Traumatic Brain Injury

TBI is the leading cause of morbidity and mortality in children, accounting for 70% to 80% of all pediatric deaths from trauma. The death rate from TBI is five times higher than that from leukemia, the next most common cause of pediatric mortality. The main source of injury is motor vehicle crashes involving passengers, pedestrians, or bicyclists. Less common sources of head injury include sports-related injuries, falls, and abuse.

Injuries to the brain are traditionally evaluated as primary or secondary injuries. Primary injuries that result from penetrating, rapid deceleration or rotational injuries occur at the moment of impact and cause physical and mechanical destruction of brain tissue; they can include parenchymal injury, diffuse axonal injuries, and cerebral edema. In comparison with primary injuries, many factors may improve or worsen secondary brain injury, which involves a complicated cascade of cellular destruction. The primary brain injury causes a certain amount of tissue and cellular death. Some injured areas of the brain (penumbra) surrounding the dead tissue may remain viable, but are vulnerable to hypoxic, ischemic, and inflammatory responses. *Aggressive management to prevent hypoxia, hypotension, and progressive edema is required to protect* *this unstable brain tissue*. If these conditions are uncorrected, secondary brain injury leads to irreversible brain damage and death.

Increased ICP

Increased ICP can have numerous etiologies. The most common cause of increased ICP in pediatric populations is related to trauma or a malfunction of an existing cerebrospinal fluid shunt.

Signs and symptoms of increased ICP may include headache, irritability, fever, dizziness, nausea, projectile vomiting, lethargy, changes in vision, unsteady gait, high-pitched cry, bulging fontanelle, pupillary dilation, seizures, coma, and Cushing triad. The symptoms become more progressive and severe as the ICP rises.

The medical management of increased ICP may include the following:

- Mild hyperventilation ($\mathrm{Pa{CO}_2}$ between 30 and 35 mm Hg). Most neurosurgeons recommend keeping the patient normocapneic.
- Administration of 3% sodium chloride (also called hypertonic saline), 4 to 6 mL/kg as a bolus, followed by a 1 mL/kg/h infusion. Alternatively, the CCTP can consider administration of mannitol (0.5 to 1 mg/kg/dose).
- Maintenance of cerebral perfusion pressure at more than 50 to 60 mm Hg (increased MAP to maintain adequate cerebral perfusion pressure).
- Elevation of the patient’s head at a 15° to 30° angle to the stretcher to promote cerebral venous drainage.
- Normothermia or mild hypothermia to decrease the metabolic rate.
- Airway management as clinically indicated.
- Pain management.
- Possible induction of coma using barbiturates (decreases the cerebral metabolic rate and oxygen consumption).

Treatment modalities may include inserting a monitor to measure ICP. This treatment is more pertinent for interfacility transports as compared to prehospital transports. A ventricular catheter is placed in the ventricles connected to an external ventricular drain; this drain evacuates fluid within the ventricle and measures objective ICP. A subarachnoid bolt placed in the subarachnoid space can also measure ICP, but cannot drain fluid and does not sound an alarm for increased pressure.

Signs and Symptoms

Increased ICP

- Headache
- Irritability
- Fever
- Dizziness
- Nausea
- Projectile vomiting
- Lethargy
- Visual changes
- Unsteady gait
- High-pitched cry
- Bulging fontanelle
- Papillary dilation
- Seizures
- Coma
- Cushing triad

Transport Management

Increased ICP

- Maintain cerebral perfusion pressure at greater than 50 to 60 mm Hg.
- Position the patient so the patient’s head is raised at a 15° to 30° angle.
- Maintain a normal or slightly elevated body temperature.
- Administer mannitol.

- Manage pain.

Normal ICP is 0 to 10 cm H_2O. An acceptable ICP is usually less than 15 to 20 cm H_2O. Cerebral perfusion pressure should be, at a minimum, 50 to 60 mm Hg to ensure adequate brain perfusion.

Concussion

Concussion is the most commonly seen type of TBI in the pediatric population. It is described as an injury to the brain resulting from a force applied directly or indirectly to the head, which may potentially produce a variety of symptoms. A concussion may or may not initially involve loss of consciousness. It results in a constellation of cognitive, somatic, emotional, and sleep-related symptoms. The duration of symptoms can vary, lasting from several minutes to several days, weeks, months, or longer. Recent data indicate that high school athletes exhibiting concussive symptoms on the playing field that resolve in less than 15 minutes will often later demonstrate deficits on formal neuropsychological testing and have reemergence of active symptoms, lasting up to a week post injury.

There are several issues of importance to the CCTP regarding concussions. First, all concussions involve some degree of injury to the brain. Second, in cases of sports-related concussions, athletes must be removed from play for a mandatory medical evaluation. Last, while it is clear that athletes—particularly children—have a greater vulnerability to reinjury following a concussion, there is lack of agreement on definitions and guidelines on when and how an athlete should be allowed to return to play. Long-term sequelae following repeated head injuries can be significant. All CCTPs should be familiar with the recommendations for evaluation of young athletes following a head injury. Current guidelines and most state laws require an on-field evaluation. The Centers for Disease Control and Prevention's Heads Up campaign provides authoritative, up-to-date information on prevention and recognition of concussions; its criteria are useful for the CCTP in assessing patients with suspected concussion.

Concussion is a mild form of TBI that, by its nature, leads to brain dysfunction induced by trauma without evidence of structural injury on standard neuroimaging studies such as computed tomography (CT) or magnetic resonance imaging of the head. In turn, diagnosis of concussion is based on symptoms. Today, the decision to obtain a head CT must be balanced with the long-term risks of malignancy from the CT radiation exposure, which is higher in children than in adults. The most comprehensive and thoroughly validated decision-making tool for use of CT in pediatric patients currently available is the Pediatric Emergency Care Applied Research Network's low-risk clinical decision rules **TABLE 24-10**.

Transport Management

Concussion

- Provide supportive measures.
- Frequently perform and document a neurologic assessment (baseline and continuous).
- Document the patient's pain level and tolerance of transport.

TABLE 24-10 Pediatric Emergency Care Applied Research Network's Low-Risk Clinical Decision Rules

Age (years)	Criteria
Up to 2 years	Normal mental status
	Normal behavior according to caregiver
	No loss of consciousness
	No severe mechanism of injury
	No nonfrontal scalp hematoma

Age (years)	Criteria
2 to 18 years	No evidence of skull fracture Normal mental status No loss of consciousness No severe mechanism of injury No vomiting No severe headache No signs of basilar skull fracture

© Jones & Bartlett Learning.

Cerebral Contusion

A **cerebral contusion** most commonly occurs at the point of impact and/or on the side opposite the impact, such as with a coup–contrecoup injury. The resulting focal hemorrhage in the brain may be associated with a concurrent concussion.

Epidural Hematoma

Epidural hematomas typically include arterial bleeding from vascular injuries after blunt trauma, most commonly involving the middle meningeal artery. This blood vessel is located just outside the dura and may be torn when a parietal skull fracture occurs. Another potential cause of epidural bleeding is damage to the diploic veins in the posterior cranial fossa, although the most common cause is a lateral temporal fossa injury. The accumulation of blood noted in these injuries does not “touch” the brain tissue. Epidural hematomas most commonly occur after blunt trauma to the head.

The classic pattern associated with epidural hematoma is a lucid period followed by rapid neurologic deterioration. However, this pattern occurs in only a minority of pediatric patients with an epidural hematoma. Children may never have a loss of consciousness or a lucid period. Epidural hematomas frequently require surgical evacuation.

Subdural Hematoma

Subdural hematomas are 5 to 10 times more common than epidural hematomas, especially in infants. These injuries are caused by shearing forces that slide the fragile brain tissue over the rough base of the skull. The hematoma occurs just below the dura, so that blood comes into contact with brain tissue. Subdural hematomas are usually caused by a disruption of bridging veins or venous sinuses beneath the dura. They can be a result of child abuse such as shaken baby syndrome. Shaking an infant violently causes acceleration–deceleration forces that shear the bridging veins in the subdural space.

Risk Assessment and Management

Many children who experience closed head trauma may have only minor injuries. Children who have low-risk injuries are often asymptomatic, with normal neurologic findings on exam. Care at home with responsible adult supervision may be all that is necessary for these patients.

Children with moderate-risk injuries will present with an altered LOC, progressive headache, or vomiting and may have an associated injury. They often require basic trauma care, including basic wound management and spinal motion restriction with radiologic evaluation.

Children with high-risk injuries will present with a depressed LOC and possible neurologic deficits or signs of increased ICP. These children often require immediate surgical interventions. Good patient outcomes require early recognition and treatment, including an early consultation with a neurosurgeon for children with high-risk injuries.

As with any traumatic injury, initial management involves stabilization of the cervical spine, airway, breathing, and circulation. All attempts should be made to prevent secondary injury, including steps to avoid hypotension and hypoxia. If clinical conditions warrant, then ET intubation should be implemented. Proper sedation and analgesia should be administered to prevent spikes in ICP.

Hyperventilation should be avoided in children who are intubated. Although routine hyperventilation is not recommended for treatment of increased ICP, it may be used emergently to transiently decrease cerebral blood flow. The benefit of creating “more room in the vault” is short-lived, however, because decreased blood flow causes hypoxia in already injured brain tissue.

Any source of bleeding in the head, including the brain, face, mandible, and scalp, can lead to significant blood loss in the pediatric patient. Hypovolemia is of great concern in children, and particularly in infants, who have a proportionally larger amount of blood volume in their heads. Even in older children, an open scalp laceration can be a significant source of blood loss that needs to be stopped while administering aggressive fluid resuscitation. The treatment goal is euvolemia, because cerebral perfusion pressure (CPP) depends on the MAP (CPP = MAP – ICP). Maintaining the patient’s head at a 30° angle and midline also improves venous outflow from the head.

The child’s mental status may be altered for a number of reasons. The most life-threatening situation involves herniation syndromes, in which increased pressure in the cranial vault causes the brain to shift. In such a case, the brain may be shifted laterally or down through the foramen magnum. The treatment of increased ICP, as discussed earlier, can include the use of osmotic diuretics such as mannitol or 3% saline. Elevating the head of the bed by 15° to 30° and elective airway management to maintain normocapnia can be considered. Children with intracranial injuries should be maintained in spinal motion restriction even if imaging performed at the referring center is negative.

Spinal Cord Injuries

Of all children who experience traumatic injuries, fewer than 4% have an injury to the spine and/or spinal cord. Although this is a relatively low incidence, mortality related to spinal cord injuries in children is more than double that in the adult population. Serious neurologic injuries are more common in older children and are often associated with sports injuries, diving injuries, or falls. High-grade injuries are most common in children after an axillary loading mechanism. The incidence of spinal cord injury dramatically increases in adolescents between 15 and 18 years of age. Of all sports-related injuries and reported spinal cord injuries, 30% to 50% involve the cervical spine and result in quadriplegia and/or severe disability.

Injuries in children younger than 8 years are most commonly found in the C1 (occiput) to C3 area, whereas older children and adults tend to have injuries in the lower cervical spine **FIGURE 24-24**. Because of the anatomic spine differences between adults and children, children are more susceptible to sustain cervical spine injuries of greater severity. By comparison, older children and adults incur injuries that are more evenly distributed throughout the cervical and thoracic spine.

Description

Similar to brain injury, spinal cord injury may occur with a primary insult and then a secondary insult. The primary insult occurs from hyperflexion (most commonly), extension, rotational injury, or compression injuries. The secondary injuries occur from biochemical reactions, including oxygen free-radical production that damages endothelial cells within the brain, ion fluxes involving extracellular potassium, ischemia, and edema. No evidence supports the empiric use of IV glucocorticoids for acute spinal cord injury.

The most important intervention in the treatment of children with known or suspected spinal cord injury is prevention of further injury through appropriate use of spinal motion restriction.

Because children have relatively weak spinal ligaments and increased mobility of the spine, they may sustain damage to the spinal cord and spinal ligaments without damage to the spinal vertebrae. This damage is called **SCIWORA**: spinal cord injury without radiographic abnormalities. SCIWORA should be suspected when there are clinical signs or symptoms of spinal cord injury in the presence of normal cervical spine radiographs. This condition is often associated with a poor neurologic outcome, a high proportion of complete neurologic injuries (no sensory or motor function below the level of injury), and a high susceptibility to delayed neurologic deficit. If a child reports pain, has difficulty with range of motion, or is unresponsive, spinal motion restriction should remain in place until additional studies can confirm there is no injury or until a skilled pediatric specialist clears the spine.

Transport Management

Spinal Cord Injuries

- Manually secure the child's cervical spine while assessing the airway.
- Immobilize the child on a pediatric or standard backboard; secure the child's body first, then the head.
- Release manual stabilization of the cervical spine.
- Reassess the child's neurologic status, and continue to reassess this status frequently during transport.

Breathing Abnormalities

Trauma and the effects of trauma may also cause upper airway obstruction. Facial trauma and soft-tissue swelling can block the upper airway. There may be direct trauma to the upper airway, such as in hanging injuries or "clothesline" injuries, or there may be secondary injury related to the trauma. Hanging injuries may occur in toddlers from crib accidents and window cords. Hanging injuries may also occur in adolescents as a method of suicide or during a "choking game," in which an individual at the point of near strangulation escapes to enjoy an altered mental state. A clothesline injury is most common in all-terrain vehicle crashes and occurs when the patient in motion is struck in the anterior neck by a stationary object (eg, a clothesline wire).

Head injury may cause a decreased LOC, which itself can depress the respiratory drive. The obtunded child's airway might be obstructed by the atonic tongue. Additionally, abnormal respiratory patterns in a child with recent head injury should raise suspicion for seizure activity.

Life threats that providers may encounter in pediatric patients with breathing abnormalities include simple pneumothorax, tension pneumothorax, open pneumothorax, hemothorax, and flail chest. Flail chest is unusual in pediatric patients because their rib calcification is poor, except in adolescents. Management of these injuries in the pediatric population is usually exactly the same as with adult patients. The following sections discuss only the differences in managing these injuries in children. For a complete discussion of these injuries, refer to Chapter 11, *Trauma*.

Tension Pneumothorax

Children with any type of pneumothorax should receive supplemental oxygen. Treatments for tension pneumothorax include a 14- to 16-gauge angio-needle decompression for older children and adolescents, with the needle being placed in the second to third intercostal space, midclavicular on the affected side **FIGURE 24-25**; alternatively, decompression may occur at the anterior axillary line, above the fifth or sixth rib. For infants, treatment is a 21- to 23-gauge butterfly needle inserted in the same location. The needle is then attached to a stopcock and a 20-mL syringe. The chest is emptied of air or fluid until the infant's condition improves. These interventions are temporizing procedures, which typically require follow-up with a larger-bore chest tube.

Description

Transport Management

Tension Pneumothorax

- For older children and adolescents, insert a 14- to 16-gauge angio-needle in the second to third intercostal space, midclavicular on the affected side; alternatively, decompression may occur at the anterior axillary line, above the fifth or sixth rib.
- For infants, insert a 21- to 23-gauge butterfly needle in the same location. Attach to a stopcock and a 20-mL syringe. Empty the chest of air or fluid until the infant's condition improves.
- If a patient with a pneumothorax requires air medical evacuation, consider the effect of altitude on the pneumothorax. Gases expand at higher altitude where there is lower atmospheric pressure. If a chest tube is clamped, the gas can expand and create tension physiology.

Hemothorax

Treatment for a hemothorax includes inserting an appropriate-size chest tube in the fifth intercostal space, anterior and midaxillary. Ideally, the chest tube will be attached to a fluid collection or suction system that allows for autotransfusion. Large amounts of blood can accumulate within the pleural cavity; as long as this blood does not become contaminated by an open wound, it can be returned to the child's circulation. This relieves the concern about draining too much blood from the pleural space. If autotransfusion collection is an option, it should be used to reduce the risk associated with donor transfusions.

Transport Management

Hemothorax

- Insert an appropriate-size chest tube in the fifth intercostal space, anterior and midaxillary.
- If available, attach the chest tube to a fluid collection or suction system that allows for autotransfusion.
- If autotransfusion collection is not possible, follow advanced trauma life support guidelines regarding how much blood should be accumulated before clamping the thoracostomy tube.
- Fluid resuscitation with blood or crystalloids may be necessary.

Abuse and Neglect

Given the high incidence of child abuse and neglect in the United States, EMS providers, including CCTPs, are likely to be called upon to care for victims of these horrific events. The primary responsibility of the transport crew is to ensure the safety of all involved.

Abuse is any improper or excessive action that injures or otherwise harms a child or infant. Forms of abuse that the CCTP must be able to recognize while caring for pediatric patients include psychological (emotional) abuse, physical abuse, sexual abuse, and neglect. While bruises in atypical locations (eg, upper back), burns, or certain fractures may be suggestive of nonaccidental trauma, the absence of such findings does not exclude abuse **FIGURE 24-26**.

Neglect is the intentional or unintentional withholding of needed care and support, which may present as a child who appears unkempt or malnourished or who has recently been diagnosed as having failure to thrive. A key component of the physical assessment at the bedside is the child's behavior. Children younger than 6 years who have experienced neglect usually appear markedly passive to their environments, whereas children 6 years or older may seem aggressive on initial evaluation.

The transport crew should conduct a thorough assessment and gather all necessary transfer documentation and radiographic studies for the receiving hospital. If a detailed assessment cannot be completed based on the pediatric patient's response, then this fact should be noted in the transfer documentation. As with any patient population, if the provider's assessment and knowledge of age-appropriate behavior do not correlate with the findings for the child, and a suspicion of abuse or neglect is present, then the CCTP must adhere to agency protocol regarding the reporting of suspected abuse or neglect. In a case of confirmed abuse, all measures should be taken to preserve evidence. Transfer documentation must reflect findings from the physical exam and statements made by the victim or suspected perpetrator. CCTPs may be requested to testify in court regarding such cases, so it is imperative to document the events and transport details with the utmost completeness and clarity.

Signs and Symptoms

Neglect

- Child appears unkempt or malnourished, or has a diagnosis of failure to thrive.
- Younger than 6 years: Child is markedly passive to the environment.
- Older than 6 years: Child seems aggressive.

Transport Management

Abuse and Neglect

- Conduct a thorough assessment.
- Adhere to agency protocol regarding reporting of suspected abuse or neglect.
- Document the events and transport details.

Hypothermia During Transport

Hypothermia exists when the patient's core body temperature is 95°F (35°C) or less. It can result from a systemic disease process, prolonged environmental exposure, or a situation in which heat production is less than heat loss by convection, conduction, or radiation. Children are at an increased risk for hypothermia secondary to their relatively larger body surface areas, proportionally large heads, immature temperature-regulating mechanisms, decreased energy stores, and lesser body fluid volume and protective fat. In particular, low-birth-weight (premature) infants, newborns, and children involved in trauma are at high risk for hypothermia.

The management of these patients starts by removing them from the cold environment, removing wet clothing, placing them under a heat lamp, and providing warm blankets and liquids **FIGURE 24-27**. As with any patient, address the ABCs during the initial/primary assessment. Warm humidified oxygen and warmed IV fluids should be administered based on the level of hypothermia. Be aware that rapid fluid replacement in this population may cause or increase the state of hypothermia. Regardless of the outside ambient temperature, CCTPs should provide additional heat from the transport vehicle's (rotor wing, fixed wing, or ground) heater. In the event of severe hypothermia, cardiopulmonary arrest may occur in children. Cardiac medications and defibrillation may not be effective when the body core temperature is less than 82.4°F (28°C); therefore, CCTPs must adhere to their agency protocols or resuscitation guidelines (Neonatal Resuscitation Program, Pediatric Advanced Life Support).

Transport Management

Hypothermia

- Remove the child from the cold environment.

- Remove wet clothing.
- Place the child under a heat lamp.
- Provide warm blankets and liquids.
- Address the ABCs.
- Administer warm humidified oxygen and warmed IV fluids based on the level of hypothermia.
- Provide additional heat from the vehicle.
- Follow agency protocols regarding cardiac medication and defibrillation.

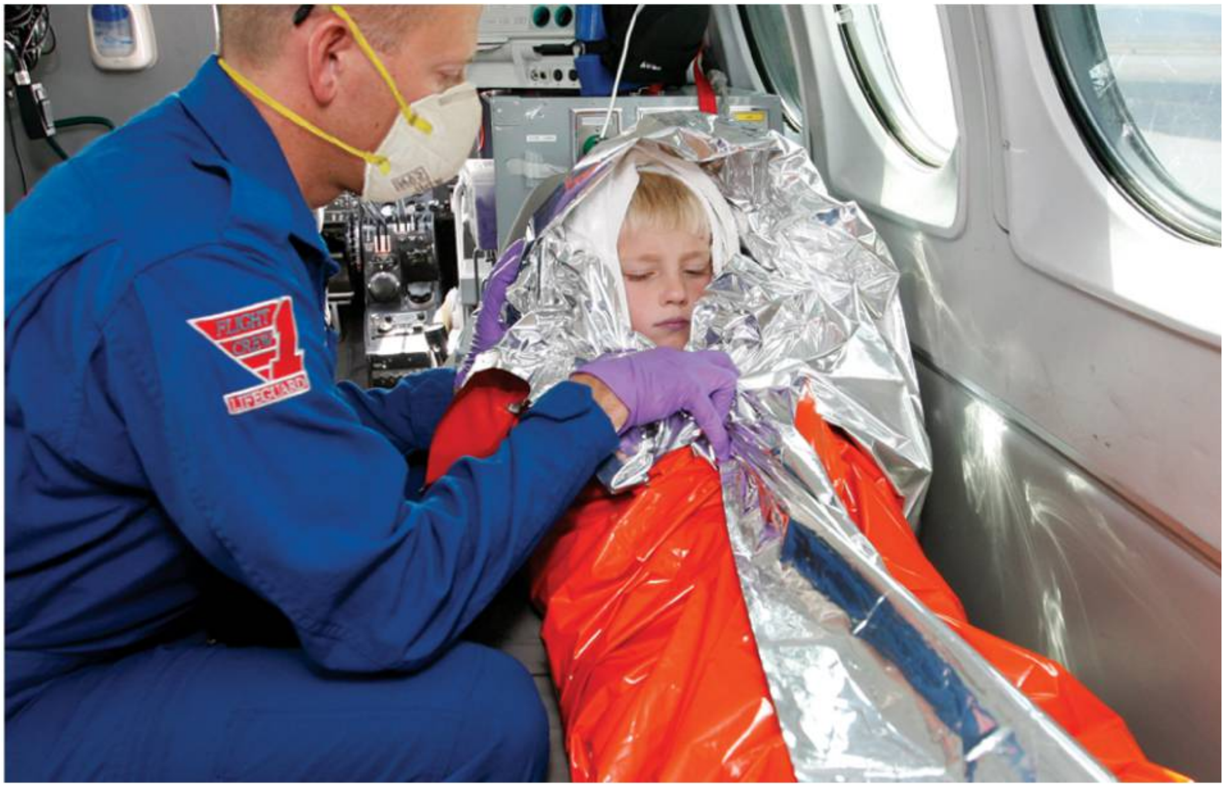

FIGURE 24-27 To manage a pediatric patient with hypothermia, remove wet clothing, place the patient under a heat lamp, and provide warm blankets and liquids.

Drowning

Drowning, also known as a fatal submersion injury, is a major cause of death for children between the ages of 1 and 14 years. Drowning rates are highest for children ages 1 to 4 years. Despite educational campaigns alerting the general public about the risk of drowning in pools and lakes for the pediatric population, a lack of awareness persists regarding the dangers posed by other hazards, including bathtubs and buckets: A child can drown in as little as 1 inch of standing water.

Most drownings are unwitnessed incidents where the victim is found floating in water. The primary insult in such cases is hypoxemia, which may or may not be attributed to aspiration. Hypoxemia as a result of aspiration begins the insult to these patients, and is followed by metabolic acidosis, hypothermia, and cardiac compromise. The key to a successful outcome is good resuscitation and a brief submersion. Secure the airway early, provide positive-pressure ventilations, and add PEEP early. Rewarm the patient and work to reverse metabolic acidosis. These patients might be on fluid restriction per their physician’s orders, or at least half maintenance infusions, and furosemide might be needed. In addition, vasopressors might be needed. Antibiotics are needed only if a bacterial infection is suspected. Patients can experience a drowning incident in fresh or salt water, although the exact etiology does not change the initial treatment. Recent research suggests that the mammalian dive reflex occurs mostly with sudden submersion in extremely cold water **FIGURE 24-28**.

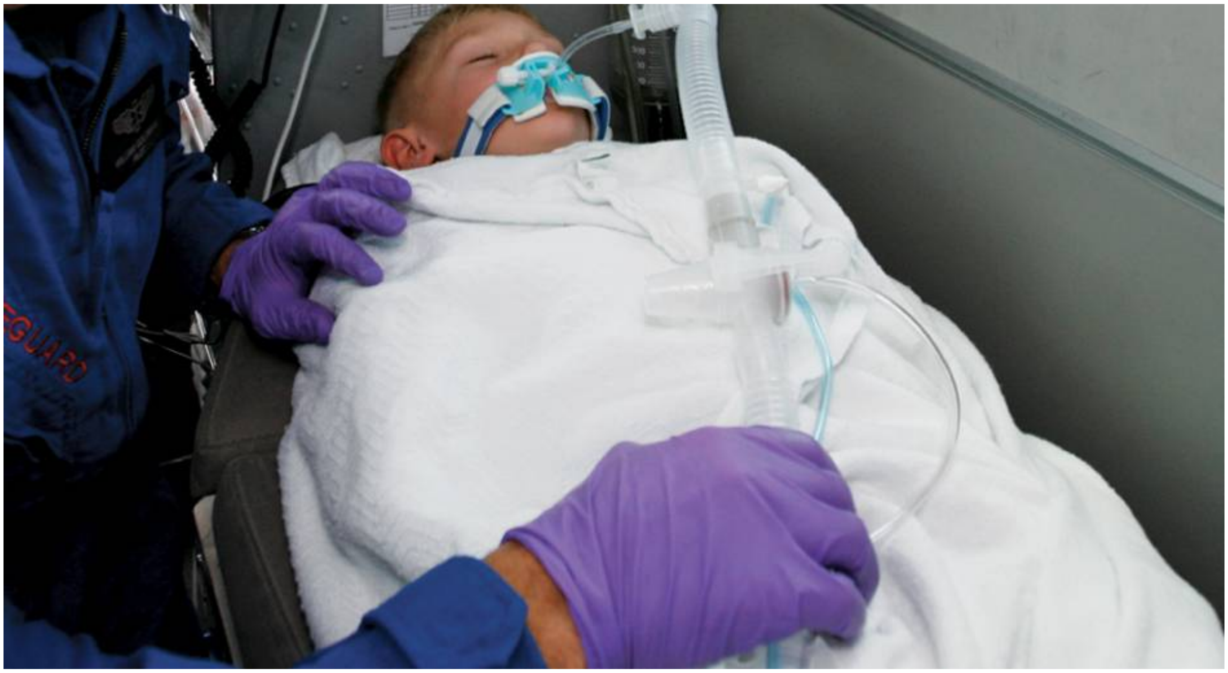

FIGURE 24-28 Early airway management with positive-pressure ventilation and PEEP should be used when treating patients with cold-water drowning.

© Jones & Bartlett Learning.

In approximately 10% to 20% of drowning incidents, the drowning occurs when the patient has a laryngospasm that prevents water from entering the lungs. The duration of the laryngospasm determines the extent of the hypoxemia. Death from this type of drowning is the result of asphyxiation, rather than aspiration.

Flight Considerations

There are no specific flight considerations for pediatric CCT; that is, the same flight considerations presented in other chapters apply to the pediatric patient. As mentioned previously, CCTPs can maintain a supply of single-use toys to help reduce the child's anxiety during transport. Such toys, as well as electronic devices, can help keep the patient calm and entertained during what may be a boring or uncomfortable journey.

In most circumstances, a parent or caregiver should be offered the opportunity to be transported with the child, as their presence may put the pediatric patient at ease with the environment. As with adult patients, never lie to pediatric patients. Use every opportunity to build their trust.

Summary

The emergency care of children is challenging and difficult under the best of circumstances. Well-guided, standardized preparation for the transport of a critically ill or injured child is essential. Working collaboratively with various organizations, such as Emergency Medical Services for Children and pediatric components of emergency medical professional organizations, allows the CCTP to provide appropriate care to this vulnerable population.

CASE STUDY

It is 0100 hours when the parents of an 11-year-old boy call EMS because he is "sucking for air." EMS arrives on the scene 6 minutes later. The paramedics immediately complete an initial/primary assessment, establish that the patient has no known allergies, and begin treatment with an albuterol nebulizer. The parents acknowledge they have been noncompliant with administering their son's rescue inhalers and nebulizers. The patient is alert and cooperative but has audible wheezing with intercostal, subcostal, and substernal retractions with tracheal tugging. The cardiac monitor reveals sinus tachycardia with a rate of 118 beats/min, a BP of 110/62 mm Hg, respirations of 36 breaths/min, and an initial SpO_2 of 84% on room air. En route to the hospital, IV access is obtained. During that time, the SpO_2 rapidly increases to 94%, and the patient's work of breathing begins to decrease.

At 0118 hours, the patient arrives at the local ED and care is transferred to the ED nurse and ED physician. A physical exam reveals a patent airway, but the patient has thick secretions that he cannot cough up. Breathing is rapid and forced. He continues to have retractions and an SpO_2 of 95% while on the nebulizer. Diminished breath sounds with expiratory wheezing are auscultated. The patient's pulses are bounding, the skin is a pale pink compared to baseline and is diaphoretic, and capillary refill is 3 seconds centrally and peripherally. The patient is cooperative but very fatigued.

At 0125 hours, the patient is started on a continuous albuterol/ipratropium nebulizer to a maximum of three doses, and he is given methylprednisolone and magnesium sulfate for management of his asthma. A chest radiograph is ordered. The ED physician calls the pediatric intensivist at the children's hospital for a possible transfer as a result of the child's history of asthma and previous intubations. The children's hospital accepts the patient to its pediatric floor, and you depart for the referring facility in a critical care ground ambulance.

Thirty minutes later, the patient's work of breathing is reported as "improving" and the chest radiograph shows the hyperinflation of the lungs typically seen in children with asthma. You arrive, begin your assessment, and obtain a report from ED personnel.

At 0202 hours, the patient becomes unresponsive and has an SpO_2 of 78% and an $ETCO_2$ of 78 with a “shark fin” appearance on the waveform. You and your partner initiate bag-mask ventilation. You immediately prepare your equipment and intubate the child with a size 6.5 ET tube and insert an orogastric tube.

After successful intubation and ET tube placement, confirmation with visualization of the tube passing the cords, fogging of the ET tube, and $ETCO_2$ monitoring, the child is given adequate pain medication sedation and paralytics, and is placed on a ventilator. His SpO_2 is now 93%, $ETCO_2$ is 45 mm Hg, and his vital signs are stable. You and your partner start an in-line nebulizer and prepare to move the patient to the stretcher for transport.

At 0221 hours, the child suddenly deteriorates as his SpO_2 decreases to 81% and his heart rate increases to 150 beats/min. The alarm on the ventilator is displaying “high pressure.” The ventilator is disconnected, and manual ventilation with a bag-mask device is initiated.

A few minutes later, the patient’s ET tube placement is reconfirmed, he is suctioned, and all equipment is working properly. He remains difficult to ventilate as a result of increased resistance, and the $ETCO_2$ increases to 60 mm Hg. Reassessment now reveals decreased breath sounds on the right side, jugular venous distention, and a decreasing BP.

At 0230 hours, you perform needle decompression on the patient’s right side. There is a rush of air and resistance to bagging decreases. The patient is then placed back on the ventilator. His vital signs are a BP of 112/61 mm Hg and a heart rate of 102 beats/min; he is being ventilated at a rate of 12 breaths/min. His SpO_2 is now 98% on an FIO_2 of 60%. He is resting comfortably under adequate sedation and pain medicine, and his condition is greatly improved.

The rest of the transport is uneventful. You and your colleagues advise the receiving physician of the changes in the patient’s condition during transport. All paperwork, treatments, and medications given are reported to the pediatric intensive care unit nurse with a copy of the transport report to be left with the patient’s chart.

1. How was the ET tube size calculated?
2. What is the treatment priority after the patient is intubated and placed on the ventilator?
3. What is the treatment priority after the child’s SpO_2 level deteriorates to 81%?
4. Which mnemonic can be used initially to help address the acute change in this patient’s status?
5. Which procedure should be performed when you observe that the child’s stomach is distended with air?

Analysis

The uncuffed ET tube size is calculated with the following formula:

$$\frac{\text{Age} + 16}{4}$$

For cuffed tubes, decrease this size by 0.5. A length-based resuscitation tape, called the Broselow tape, can also be used to select the ET tube size. Remember, ET tube size formulas are only guides for ET tube selection. ET tubes that are 0.5 mm smaller and larger must be readily available.

After the child is intubated and placed on the ventilator, the treatment priority is sedation and possibly pain medication. When you observe the patient’s stomach distended with air, a nasogastric or orogastric tube should be inserted to decompress the stomach and reduce the risk of aspiration.

When the child deteriorates to an SpO_2 of 81%, the treatment priority is assessment of the ABCs. At this point, the CCTP should take the patient off of the ventilator and manually ventilate the patient with a bag-mask device.

The DOPE acronym is used to help remember how to care for this deteriorating patient. It stands for Dislodgement of the tube, Obstruction of the tube, Pneumothorax, and Equipment failures.

When the crew discovers a pneumothorax, the next treatment priority is needle decompression. In pediatric populations, patients may still have an equal rise/fall of the chest and audible lung sounds on both sides of the chest. Children typically have thin chest walls and lung sounds “echo” to the affected side from the unaffected side. In addition, the inflated lung may still elevate the side of the chest with the collapsed lung, a phenomenon related to the pliable and compliant chest walls of children.

Children with asthma are at a greater risk for pneumothorax because of hyperinflation of the lungs and high airway pressures. In most cases, the air can get in, but it has difficulty getting out. Particular caution must be taken with children during bag-mask or mechanical ventilation. Slow down your expiration time for these patients. Some children may need I:E times of 1:3 to 1:5. Assess, treat, and *reassess*!

PREP KIT

Ready for Review

- The basic anatomy of the cardiovascular system is the same in children as in adults, but there are physiologic differences, such as differences in normal ranges for pulse rate and blood pressure (BP) and children's limited duration of compensatory mechanisms.
- Children's respiratory systems—lungs that continue developing through adolescence, smaller lower airways, smaller number and size of peripheral airways, immature alveoli, and decreased collateral ventilation—put them at higher risk for severe symptoms caused by respiratory diseases and for atelectasis.
- Infants' highly reactive airways make them more vulnerable to environmental allergens, viral respiratory diseases, and hereditary factors.
- Children are more susceptible to brain injuries because their brains are not well compartmentalized, which means there is more room for the brain to move in the skull.
- A normal fontanelle is soft and flat but has a feeling of fullness. The posterior fontanelle closes at 2 months of age, and the anterior fontanelle closes at 16 to 18 months of age.
- Cephalohematoma occurs in 1% to 2% of live births involving mechanical trauma, and is found predominantly in the parietal region of the skull. It usually resolves in 6 to 8 weeks and can be associated with linear fractures. The critical care transport professional (CCTP) should note the size and location of the hematoma during initial assessment and during transport. Possible complications are rare but include infection, hyperbilirubinemia, meningitis, and osteomyelitis.
- Caput succedaneum is soft-tissue swelling in a neonate's head that usually resolves within 24 hours.

- Children’s bones are more porous than adults’ bones, and tend to buckle rather than fracture. Epiphyseal–metaphyseal growth plate injuries account for 10% to 15% of fractures in children; with reduction and immobilization, most have excellent outcomes.
- The child’s thorax is pliable and able to absorb a significant amount of energy without fracturing. A small or suspected rib fracture may indicate a severe pulmonary contusion, which is more life threatening to the child than the rib fracture.
- Children’s ligaments are strong and more resilient than those of adults, making their joints strong and dislocations rare.
- Because of a highly flexible cervical spine, young children tend to have avulsions rather than fractures. They are more susceptible to head injuries because they have relatively large, heavy heads with weak neck muscles.
- Children have a higher risk of aspiration as a result of an immature cardiac sphincter, are more susceptible to blunt abdominal trauma because they have weaker abdominal muscles, and are susceptible to hypoglycemia as a result of immature liver function.
- Children are more susceptible to dehydration than adults are because they have a higher percentage of body water. Minimum urine outputs are 2 mL/kg/h for infants and 1 mL/kg/h for children, compared to 0.5 mL/kg/h for adults.
- Infants and children exposed to extremes of cold are at higher risk for hypothermia compared to adults because their ability to regulate temperature is not fully developed and they have a larger body surface to mass ratios.
- Close monitoring of oxygen and medication consumption is essential with children because they have a higher rate of metabolism and consume more oxygen than adults do. The rate of onset of hypercapnia and hypoxemia is accelerated in pediatric patients.
- The CCTP should monitor the pediatric patient closely for hypoglycemia, which can manifest with a rapid onset and either an asymptomatic or classic presentation. Treatment depends on the

patient’s weight and age. Administration of 50% dextrose is contraindicated in the pediatric population.

- An understanding of normal growth and development, as well as the individual pediatric patient’s developmental level, helps guide assessment, safety considerations, and communication techniques.
- Care strategies for psychosocial concerns vary with the age of the child. Speaking at eye level, using first names, and explaining medical procedures with age-appropriate words are techniques that can be used at all age levels. Maintaining a calm and confident manner also helps to reassure both the child and the parent.
- CCTPs need to be academically, technically, and emotionally prepared to care for pediatric patients. They must recognize and address the needs of the parents, guardians, or caregivers, as well as those of the patient.
- Pediatric assessment begins with the pediatric assessment triangle (PAT), which assesses the child’s appearance, work of breathing, and circulation.
- After using the PAT to form a general impression of the patient, perform an initial/primary assessment. Any abnormal finding indicates the need for immediate treatment and may require deferral of the next step. Perform a secondary assessment on medical and trauma patients.
- Assess all children for pain. A numeric scale can be used for older children and adolescents; the FLACC or FACES scale can be used for infants and young children.
- The CCTP can get extensive information for the child’s history from the child’s parents or caregivers. Scene or situation information may also be useful.
- Pediatric medication doses often have to be calculated, which increases the possibility of errors; doses of high-alert medications require an independent recheck before they are administered.

- The CCTP should be familiar with pediatric medications used for critical care transport and the different methods of medication delivery. The best option for administering resuscitation medications is a vascular access device.
- Nasal congestion can be life threatening to an infant because infants are obligate nose breathers. Normal saline spray and a bulb syringe can be used to clear the nasal airways. Positioning the infant with the head up at a 30° to 45° angle also aids in keeping the nasal airways clear. Administration of oxygen via a nasal cannula may work as well.
- Airway differences and other factors, such as infection, trauma, or foreign body airway obstruction, can impair the patency of the child's airway. Proper choice of blade size, proper positioning, and effective sweeping of the tongue are essential for successful intubation. Assess the corneal reflex to determine if the child has a gag reflex before inserting the oral airway.
- Assessment of the work of breathing in children should include observation for stridor, snoring, retractions, head bobbing, accessory muscle use, tripoding, nasal flaring, wheezing, and grunting. The CCTP should know the parameters for normal pediatric vital signs but should remember to assess the patient, not the numbers or monitors. Assessment of the child's level of consciousness (LOC), palpation of the child's chest, and auscultation are used to assess breathing adequacy. Measurements used to determine breathing adequacy include percentage of hemoglobin molecules that are bound with oxygen (SpO_2), end-tidal carbon dioxide ($ETCO_2$), and arterial blood gas readings.
- Assessment of a child's cardiovascular system includes observing the child's general appearance and LOC, including assessing the child's fingers and toes for evidence of clubbing; obtaining vital signs; assessing the child's skin, which should be warm, dry, and the appropriate color; and measuring the child's BP. The capillary refill time is a good predictor of peripheral perfusion. For some

disease processes, mean arterial pressure may be a more important measure in guiding treatment than BP.

- Any trauma or medical condition that causes fluid loss requires intravenous (IV) access for volume replacement. Intraosseous (IO) insertion is recommended when rapid venous access cannot be obtained. The most common site for IO insertion is the anterior tibia. Contraindications to IO access include osteogenesis imperfecta, osteopetrosis, and fractures of the ipsilateral extremity.
- Urine output can be an objective indicator of pediatric circulatory status and the effectiveness of volume replacement. Low urine output indicates poor kidney perfusion.
- Neurologic assessment includes evaluating the child’s general appearance, assessing the fontanelles, checking the child’s pupil size and response to light, and evaluating muscle tone and reflexes, including the Moro reflex and the stepping reflex. Protective reflexes are lost in ascending order.
- The Glasgow Coma Scale is a sensitive indicator of mental status; it is modified when examining infants and children.
- Assessment of the renal system includes evaluation of hydration status and physical assessment, including assessment of the fontanelles in infants, assessment of skin turgor, the presence or absence of tears when crying, and sunken eyes. Daily weights are an objective measurement; acute weight loss may indicate fluid loss.
- Fluid overload is less common in children than in adults, but it may occur in patients with congenital heart defects or renal insufficiency. Hypoxia and grunting are early signs of pulmonary edema. Additional signs of fluid overload include weight gain, edema, history of intake greater than output, and pulmonary edema. Early signs of pulmonary edema may be discounted because of this condition’s subtle presentation, but it can be confirmed by a chest radiograph.

- Resuscitation of infants and children must include measures to maintain body temperature because of children’s physiologic differences. Measures must be taken to prevent hyperthermia and hypothermia.
- CCTPs who anticipate caring for critically ill or injured children need knowledge and skills specific to caring for infants and children as well as practice in pediatric care and mentoring from professional colleagues who care for pediatric patients on a regular basis.
- Equipment necessary for pediatric care should be available when transporting infants and children. All equipment and supplies should be secured prior to transport to reduce the possibility of injury in the event of a crash.
- A team approach to interfacility transfer is best. Communication tools such as SBAR (situation, background, assessment, and recommendation) help to standardize the exchange of information among providers. The team should have a contingency plan for resuscitating the child if necessary during transport, and the driver or pilot should be prepared to respond if changes in the patient’s condition or in the weather prevent completion of the transport.
- For safe transport, pediatric patients and health care providers must be secured in the vehicle and appropriate protective gear should be used. Interventions needed to stabilize the patient should be performed before beginning transport. CCTPs need to be aware of local, regional, and national protocols for addressing the increased risks of air medical transport and be prepared to take measures to reduce them.
- Guidelines for transporting parents or caregivers with a child should be in place before a child needs transport. Safe transport of the child is the priority, and the caregiver’s comfort level and the potential for disruption of care during transport must be taken into account.
- The American Academy of Pediatrics recommends that self-inflating bags be used for resuscitation of children. CCTPs who

will be caring for children should be familiar with the use of self-inflating bags, as well as the use of flow-inflating bags, oxygen hoods, shortened tracheal tubes, and laryngeal blade options.

- Respiratory illness is a common reason for pediatric transport. Upper airway conditions, lower airway conditions, parenchymal diseases, and abnormal control of ventilation can lead to upper airway failure.
- Respiratory distress is characterized by increased work of breathing. Although the effort to breathe is increased, the child may still have adequate exchange of oxygen and carbon dioxide. The additional effort may also occur for compensatory reasons.
- The definition of respiratory failure depends on the child’s baseline respiratory function. Intervention to prevent respiratory or cardiac collapse is paramount. The CCTP should take all measures (per protocol) to maintain and preserve a patent airway and hemodynamic status before transport begins.
- Croup is a common viral infection characterized by a hoarse, “barking seal” cough that often becomes worse at night. Its management ranges from the administration of humidified oxygen, to the administration of racemic epinephrine, to oral intubation in severe cases of obstruction.
- Epiglottitis is a bacterial infection that most commonly occurs in children ages 3 to 5 years. Symptoms include the four Ds: dysphagia, dysphonia, drooling, and distress. A calm environment should be maintained, and a definitive airway should be secured prior to transport. Use of racemic epinephrine is contraindicated.
- Foreign body aspiration causes more than 90% of pediatric deaths in children younger than 5 years. Its onset may be dramatic, with an immediate life threat or with varying severity. Removal of the foreign body should be attempted only by following American Heart Association and American Academy of Pediatrics guidelines.
- Early recognition of upper airway inflammation and intervention are imperative to lessen the morbidity and mortality associated

with this condition. Therapeutic measures are the same as for all upper airway obstructions: Maintain a calm environment, administer humidified oxygen, provide a position of comfort, and prepare for deterioration of the airway status.

- Bronchiolitis is a viral infection caused by respiratory syncytial virus or another virus that primarily affects infants and young children. Symptoms may vary from mild wheezing to severe respiratory distress. Treatment is supportive, with IV fluids, oxygen, and positive pressure being administered when needed. There is no role for routine use of bronchodilators or steroids in the management of bronchiolitis. Ribavirin, an antiviral drug, should be administered as prophylaxis to high-risk neonates. Diligent assessment and monitoring of the child’s work of breathing before and during transport are critical.
- Asthma is a chronic inflammatory disorder of the lower airways that results in a significant number of pediatric transports. When transport is required, traditional treatments have likely failed and more advanced therapies are required. If a child has a history of requiring intubation for severe asthma, all treatments should be given during rapid transport to the hospital. Management includes oxygen therapy and the administration of a bronchodilator and corticosteroids.
- Pneumonia is a parenchymal lung disease. Infants and children may not tolerate pneumonia as well as older children and adults do. Transport treatment includes vigilant assessment of the work of breathing and hydration status. Antibiotic therapy is required and may have been started at the initial facility.
- The presentation of acute respiratory distress syndrome is similar in children and adults. In addition to reversing the underlying etiology, management is primarily supportive.
- As noninvasive methods of mechanical ventilation become increasingly popular, providers must be proficient in the following methods: heated high-flow nasal cannula, continuous positive airway pressure (CPAP; including “bubble CPAP” for infants),

bilevel positive airway pressure (BPAP), and nasal noninvasive positive-pressure ventilation (essentially BPAP with a rate).

- CCTPs may be asked to initiate or manage invasive methods of maintaining difficult airways, including rescue devices and medications to facilitate rapid sequence intubation. Further, CCTPs should be familiar with different ventilation strategies for the patient, once intubated.
- Pediatric cardiac conditions are common indications for transport. CCTPs will routinely be involved in transport of children with four types of heart disease or conditions: known cardiac defect, unknown or suspected cyanotic defect, cardiac arrhythmia, or some form of shock.
- Electrocardiogram (ECG) rhythm interpretation is different for children than for adults. Normal values vary with the child’s age. It may be helpful to increase the ECG monitor sweep speed to identify subtle nuances in the components of the ECG.
- Depending on the severity, congenital heart defects may require immediate surgery or supportive care until the child is older and able to tolerate surgical intervention. Children with a known or new-onset cardiac condition may present with a defect in their cardiac pumps.
- Pediatric patients can experience both bradyarrhythmias and tachyarrhythmias. CCTPs should be familiar with the range of normal heart rates in children; misunderstanding what is normal for a given age group is a frequent contributor to errors in diagnosing cardiac disorders.
- In the event of cardiac arrest during ground transport, providers should stop the ambulance in a safe location to facilitate high-quality cardiopulmonary resuscitation. If resuscitation does not rapidly result in return of spontaneous circulation, providers should follow preestablished agency policies that direct the ambulance to the closest hospital.
- Shock may lead to rapid death or may be more progressive. It is categorized as compensated or uncompensated, based on the

child’s BP.

- Hypovolemic shock, which is characterized by inadequate intravascular volume, is the most common cause of shock in pediatric populations.
- There are four stages of hypovolemic shock: (1) The child appears asymptomatic; (2) the child maximizes compensatory mechanisms; (3) the child is no longer able to compensate and hypotension occurs; and (4) death is imminent if the volume loss is not eliminated and aggressive volume replacement is not initiated. Resuscitation is deemed successful when there is a return to normal heart and respiratory rates, normal BP, and improved mental status and skin condition.
- The child with cardiogenic shock presents with traditional signs of shock, pulmonary congestion, and jugular venous distention. Treatment focuses on improving cardiac function with fluid resuscitation, inotropic support, and pharmacologic support.
- Neurogenic shock, anaphylactic shock, and septic shock are types of distributive shock. Treatment focuses on stopping vasodilation, returning volume to the intravascular space, and improving tissue perfusion.
- Symptoms of anaphylactic shock include increased general body edema, hypotension, rash, urticaria, anxiety, and warm, flushed skin. A child in anaphylactic shock may also experience bronchospasm and laryngeal edema, which may be life threatening. Management involves removing the allergen, replacing volume, and administering epinephrine.
- Systemic inflammatory response syndrome and sepsis are both clinical shock syndromes characterized by inflammation, vasodilation, significant microvascular permeability, and accumulation of leukocytes resulting in hypoperfusion and end-organ dysfunction. Early recognition and aggressive resuscitation are key to good outcomes with these conditions.
- Causes of acute kidney injury (AKI) are divided into three categories: prerenal, intrarenal, and postrenal.

- Prerenal causes of AKI are the most common in children and are primarily related to dehydration and decreased renal perfusion.
- Intrarenal or parenchymal causes of AKI are diverse, but all lead to nephron damage and loss of glomerular function. Hemolytic uremic syndrome is one of the most common causes of intrarenal AKI in infants and children younger than 4 years. Acute glomerulonephritis, acute postinfectious glomerulonephritis, and acute tubular necrosis are also intrarenal causes of AKI.
- Postrenal or obstructive failure can cause irreversible parenchymal damage if not treated.
- Potentially life-threatening complications of AKI include electrolyte imbalances such as hyponatremia, hypocalcemia, and hyperkalemia; volume loss or pulmonary edema and fluid overload; volume overload; hypertension; and hypertensive encephalopathy.
- The presentation of the pediatric patient with meningitis depends largely on the child’s age, the type of organism, and the present state of the child’s health. Standard universal precautions should be taken with all pediatric patients with suspected meningococcal infection.
- Trauma is the leading cause of death for all pediatric patients 1 year or older. Injuries in children most commonly involve motor vehicle crashes, suffocation, submersion, burns, falls, and violence. The two main resources for CCTPs when assessing pediatric trauma patients are the Glasgow Coma Scale, which has been altered for pediatric patients, and the pediatric trauma score.
- Head trauma is the leading cause of morbidity and mortality in children. Injuries to the brain are evaluated as primary or secondary injuries.
- Primary injuries occur at the moment of impact and cause physical and mechanical destruction of brain tissue. Secondary injuries are injured areas of the brain that may remain viable but are vulnerable to hypoxic, ischemic, and inflammatory responses. If

untreated, secondary brain injury leads to irreversible brain damage and death.

- The most common cause of increased intracranial pressure in pediatric populations is related to trauma or a failed cerebrospinal fluid shunt.
- Concussion is the most commonly seen head injury in the pediatric population. If concussion is suspected, the CCTP should provide supportive measures during transport, perform and document a neurologic assessment, and document the patient’s pain level and tolerance of transport.
- Other head injuries that CCTPs may encounter with children are cerebral contusion, epidural hematoma, and subdural hematoma. Subdural hematoma can be caused by child abuse, such as shaken baby syndrome.
- Spinal cord injuries in children are relatively rare, but mortality related to such injuries in children is more than double that in adult populations. As with brain injuries, spinal cord injuries may occur with a primary insult and then a secondary insult.
- The most important intervention with spinal cord injuries is proper spinal motion restriction. A properly fitting cervical collar and, ideally, a pediatric backboard should be used. If a pediatric backboard is not available, a standard backboard can be used with adaptations to accommodate the child.
- Children may sustain damage to the spinal cord and spinal ligaments without damage to the spinal vertebrae. This damage is called SCIWORA, which stands for spinal cord injury without radiographic abnormalities. SCIWORA is suspected when there are clinical signs or symptoms of spinal cord injury but the cervical spine radiographs are normal.
- Facial trauma, soft-tissue swelling, hanging injuries, and clothesline injuries can cause upper airway obstruction. The patient’s tongue can also obstruct the airway. Simple pneumothorax, tension pneumothorax, open pneumothorax, hemothorax, and flail chest may threaten the child’s life.

Management of these conditions is generally the same for children as for adults. The CCTP should be aware of differences in managing these conditions in children.

- CCTPs must adhere to agency protocol regarding reporting suspected child abuse or neglect. In cases of confirmed abuse, they must preserve evidence. CCTPs may be requested to testify in court, so it is important to document findings from the physical exam, statements made by the victim or suspected perpetrator, and transport details.
- Children are at higher risk for hypothermia than adults. Hypothermia exists when the patient’s core body temperature is 95°F (35°C) or less. CCTPs should adhere to agency protocols or resuscitation guidelines for treating children with hypothermia.
- Drowning is a major cause of death for children ages 1 to 14 years. Educating the public about drowning hazards remains a top priority in emergency medical services.

Vital Vocabulary

acute glomerulonephritis (AGN) A histopathologic diagnosis associated with edema, hypertension, and hematuria; results from deposition of circulating immune complexes in the kidney basement membrane, which ultimately causes reduced glomerular filtration.

acute kidney injury (AKI) Decreased renal function in the absence of preexisting renal disease. Classified into three categories: prerenal, intrarenal, and postrenal.

acute postinfectious glomerulonephritis (APSGN) A form of acute glomerulonephritis that occurs following an infection by streptococci.

acute tubular necrosis (ATN) A condition that results in damage to the tissue of the kidneys’ tubules.

aerophagia A condition in which the stomach fills with excessive air secondary to increased respiratory rate.

anaphylactic shock A potentially life-threatening allergic reaction that presents with increased general body edema, hypotension, rash, urticaria, anxiety, and warm, flushed skin.

atelectasis Complete or partial lung collapse.

bandemia Release of excessive numbers of band cells from the bone marrow into the blood.

bradypnea A slow respiratory rate.

bronchiolitis A condition seen in children younger than 2 years, characterized by dyspnea and wheezing.

Brudzinski sign Passive flexion of the legs and thighs when the examiner flexes the patient’s neck to the chest. If this causes pain or causes the knees and hips to flex involuntarily, the sign is positive.

caput succedaneum Soft-tissue swelling in a neonate’s head owing to fluid collection.

cardiogenic shock Shock caused by failure of the heart’s ventricles to pump adequate amounts of blood; it may be caused by congenital cardiac defects, drug toxicity, metabolic causes, hypovolemia, myocarditis, and arrhythmias.

cephalohematoma A collection of blood between the bone and subperiosteal space.

cerebral contusion A focal brain injury in which brain tissue is bruised and damaged in a defined area.

clubbing Broadening of a child’s fingers and toes in response to chronically low oxygen levels for longer than 3 months.

concussion A transient interruption of normal neurologic function.

croup A childhood viral disease characterized by edema of the upper airways with barking cough, difficult breathing, and stridor; also called laryngotracheobronchitis.

distributive shock A form of shock in which the smallest blood vessels fail to deliver adequate blood to the tissues; it includes neurogenic shock, anaphylactic shock, and septic shock.

epiglottitis Inflammation of the epiglottis.

FLACC scale A pain assessment scale that scores points for five categories, including face, legs, activity, cry, and consolability.

Glasgow Coma Scale (GCS) A scale used in neurologic assessment, which scores patients on eye opening, verbal, and motor performance.

hemolytic uremic syndrome (HUS) A serious condition in which the patient develops acute kidney injury, and which also causes anemia and thrombocytopenia; thought to be caused by several bacterial and viral infectious organisms, most often verotoxin-producing strains of *Escherichia coli*.

hyperkalemia An increased level of potassium in the blood.

hypocalcemia A low level of calcium in the blood.

hyponatremia A blood serum sodium level that is below 135 mEq/L, and a serum osmolarity level that is less than 280 mOsm/kg.

hypovolemic shock The most common cause of shock in pediatric populations, which is characterized by inadequate intravascular volume.

intrarenal acute kidney injury A type of acute kidney injury caused by damage to an actual nephron.

Kernig sign Resistance and pain elicited on extension of the leg at the knee, with the patient in the supine position and the hips flexed perpendicular to the trunk; when pain occurs as a result of this test, the test result is positive.

Moro reflex An infant reflex in which, when an infant is caught off guard, the infant opens their arms wide, spreads the fingers, and seems to grab at things.

neurogenic shock A form of shock that results in low blood pressure.

neutropenia Abnormally low concentration of neutrophils (white blood cells) in the blood.

osteogenesis imperfecta A congenital disorder in which the individual has brittle bones that are susceptible to fracture; also known as brittle bone disease or Lobstein syndrome.

osteopetrosis An inherited disorder in which the bones become extremely hard and dense.

pediatric assessment triangle (PAT) An assessment tool that allows rapid formation of a general impression of the type and level of illness or injury in an infant or child without touching the patient; consists of assessing appearance, work of breathing, and circulation to the skin.

postrenal acute kidney injury A type of acute kidney injury caused by downstream obstruction of urine flow from the kidneys, with initially intact nephrons; commonly caused by a blockage of the urethra by prostate enlargement, renal calculi, or strictures.

prerenal acute kidney injury A type of acute kidney injury caused by decreased perfusion of an intact nephron; often reversible if the underlying condition can be found and perfusion can be restored to the kidney.

reactive airway disease (RAD) Any condition that causes hyperreactive bronchioles and bronchospasm.

SCIWORA Spinal cord injury without radiographic abnormalities.

sepsis A life-threatening complication of infection, in which the entire body mounts an immune response.

stepping reflex An infant reflex that occurs when the infant is held up in the air and moves the legs up and down as if marching.

systemic inflammatory response syndrome (SIRS) A clinical shock syndrome characterized by inflammation, vasodilation, significant microvascular permeability, and accumulation of leukocytes resulting in hypoperfusion and end-organ dysfunction.

tachypnea Shallow, rapid respirations.

TICLS A mnemonic used to remember the priorities during initial assessment of an infant's appearance: Tone, Interactiveness, Consolability, Look or gaze, and Speech or cry.

CHAPTER 25

Bariatric and Special Situations

Bariatric Patients:

Peter Dworsky, MPH, EMT-P, CEM, FACPE

Excited Delirium:

Eric Silverman, MD, MPH

Children With Special Health Care Needs:

Emily J. Kivlehan, MD, MS

Lindsay Riedl, MD

OBJECTIVES

After completing this chapter, you will be able to:

1. Describe the major types of bariatric procedures, including potential complications from those procedures (pp 1361–1363).
2. Discuss considerations related to oxygen consumption in bariatric patients (p 1364).
3. Describe safe methods of moving bariatric patients from the facility to the stretcher, and vice versa, and of moving the stretcher to and from the ambulance (pp 1366–1370).
4. Explain reimbursement issues related to bariatric-specialty units (pp 1371–1372).
5. Discuss excited delirium, including its risk factors, pathophysiology, signs and symptoms, and management (pp 1372–1375).
6. Discuss the elements of interfacility transport monitoring of patients with excited delirium (p 1377).
7. Describe the unique considerations that arise with the critical care transport of pediatric patients with special needs, including children with congenital heart defects; hematology–oncology pediatric patients; pediatric patients with venous access devices; and pediatric patients with respiratory, neurologic, and gastrointestinal disorders (pp 1379–1391).

Introduction

Critical care transport professionals (CCTPs), no matter where they practice, are likely to encounter diverse populations, including some special populations with unique needs. This chapter covers three of these special populations: bariatric patients, patients with acute agitation or violent behavior, and pediatric patients with special needs.

Obesity rates in the United States have more than doubled in the past 3 decades, prompting an increase in bariatric procedures. The care and transport of bariatric patients, especially when not done on a routine basis, requires careful planning to provide the best outcomes for the patient and transport crew.

Excited delirium, sometimes called agitated delirium, is a potentially fatal condition. Many patients with this syndrome have developed it as a result of substance abuse or psychiatric disorders, and their aggressiveness can put anyone at the scene, including themselves and the transport crew, at risk.

Children with special needs include those with congenital heart defects; hematologic–oncologic conditions; respiratory, neurologic, or gastrointestinal disorders; or dependency on technology for survival. To ensure optimal outcomes for these vulnerable patients, CCTPs must be able to treat the patient while communicating with parents and/or caregivers.

Bariatric Patients

A relatively new area in which critical care transport (CCT) units have become involved is the transport of patients with obesity, referred to as bariatric patients. **Obesity** is an unhealthy accumulation of body fat, defined as a body mass index (BMI) greater than or equal to 30 kg/m^2. This is a good general guideline, except in cases where body weight does not correlate to excess fat, such as in very muscular people. The Centers for Disease Control and Prevention (CDC) further defines obesity as follows:

- Class 1: BMI of 30 kg/m^2 to <35 kg/m^2
- Class 2: BMI 35 kg/m^2 to <40 kg/m^2
- Class 3: BMI of 40 kg/m^{2}or higher

Health risks increase with each increase in class. In the United States, more than 40% of adults have a BMI greater than 30 kg/m^2 and, therefore, are considered to have obesity. More than 50% of children and adolescents in the United States have obesity.

The CDC would term class 3 obesity as **morbid obesity**. Morbid obesity includes all of the health risks associated with obesity, but also makes essential functions such as walking or breathing difficult.

People who are overweight are also at increased risk for disease, although their risk is not as high as for those persons who have obesity. Being **overweight** is defined as having a BMI of 25 to 29.9 kg/m^2.

It should be noted that the United States is not alone in its battle against excess body weight. According to the US Surgeon General, in the last 20 years, the prevalence of obesity has doubled, with worldwide estimates of 1.1 billion people classified as overweight and 250 million people classified as having obesity.

Obesity has widespread and diverse long-term negative effects on all organ systems in the body **TABLE 25-1**. These effects are often manifested during the transport phase, as the patient is brought into a less-than-ideal setting with uncontrollable environmental factors that place additional stressors on these systems.

TABLE 25-1 Effects of Obesity on Organ Systems

Organ System	Disease States
Cardiovascular	Hypertension, coronary artery disease, heart failure, cerebral vascular accident (stroke), peripheral vascular disease
Pulmonary/respiratory	Positional apnea, asthma, chronic obstructive pulmonary disease, acute respiratory distress syndrome
Metabolic	Diabetes
Gastrointestinal	Gastroesophageal reflux disease, renal failure, liver and gallbladder disease
Musculoskeletal	Gout, back injuries

Types of Bariatric Procedures

Bariatric procedures are becoming increasingly common in the United States. According to the American Society for Metabolic and Bariatric Surgery, the number of bariatric procedures increased from approximately 16,000 procedures per year in the early 1990s to approximately 252,000 procedures in 2018. Several types of bariatric procedures are currently performed, including laparoscopic adjustable banding, vertical banded gastroplasty, sleeve gastrectomy, biliopancreatic diversion with duodenal switch, Roux-en-Y (“roo-en-y”) anastomosis, and intragastric balloon insertion.

Laparoscopic Adjustable Banding

Laparoscopic adjustable gastric banding (LAGB) is the least invasive bariatric surgical procedure **FIGURE 25-1**. In this procedure, one large incision site, approximately 1.5 inches (4 cm) long, is placed in the upper abdomen for the laparoscopy port. Four smaller incisions are used as insertion points for instrument trocars.

Diaphragm
Esophagus
Adjustable gastric band
Small intestine
Remainder of stomach

FIGURE 25-1 Laparoscopic adjustable gastric banding.

© Jones & Bartlett Learning.

Description

In recent years, this five-incision procedure has been modified to become a one-incision procedure. In the one-incision LAGB procedure, a single incision is placed just below the left ribs;

alternatively, it can be hidden in the umbilicus. Passage and placement of the band are all conducted through this single incision.

The LAGB procedure, without complications, takes approximately 90 minutes to perform. During that time, an adjustable band is placed around the upper portion of the stomach, with an adjustment port located on the right side of the abdomen, under the skin. The band divides the stomach, creating an upper pouch that can hold approximately 0.5 cup (118 g) of food. The port, located just below the skin, can be accessed to decrease the size of the opening between the upper and lower portions of the stomach. Injecting saline into the port increases the amount of constriction the band provides.

The mortality rate for LAGB, whether it involves one incision or five incisions, is less than 1%.

Vertical Banded Gastroplasty

Vertical banded gastroplasty (VBG), also known as "stomach stapling," divides the stomach into two parts **FIGURE 25-2**. Staples, in conjunction with a polypropylene band or Silastic ring, are used to create a small stomach pouch with a small (about the size of a dime) opening that empties into the larger, lower part of the stomach. Plastic mesh is used to strengthen the opening and keep it from stretching. During the procedure, the front wall of the stomach is stapled to the back wall. VBG is performed laparoscopically and no part of the stomach is removed.

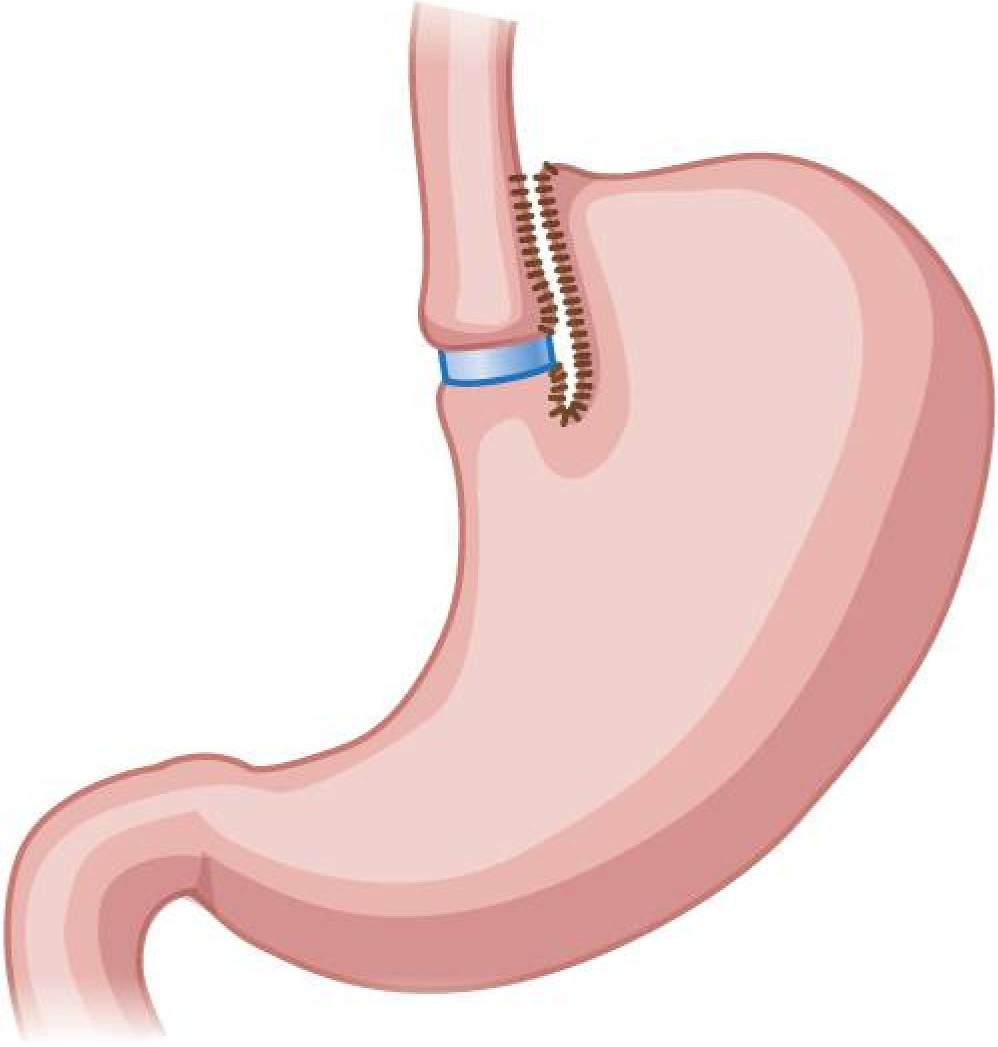

FIGURE 25-2 Vertical banded gastroplasty.

© Jones & Bartlett Learning.

Sleeve Gastrectomy

Sleeve gastrectomy, also known as vertical sleeve gastrectomy, is the first part of a biliopancreatic diversion with duodenal switch procedure **FIGURE 25-3**. During this procedure, the structure of the stomach is changed to a tube, restricting the amount of calories the body can absorb; specifically, approximately 80% of the stomach is removed. Like the VBG and LAGB, a sleeve gastrectomy is performed laparoscopically using five incisions, and the stomach is reshaped using surgical staples. This procedure is not reversible and has a higher complication rate than the LAGB procedure.

Biliopancreatic Diversion With Duodenal Switch

Biliopancreatic diversion with duodenal switch (BPD/DS) is generally used in patients who have BMI greater than 50 kg/m^2. This two-part procedure requires reshaping of the stomach and bypassing of a large portion of the small intestine **FIGURE 25-4**. Weight loss occurs due to decreased intake and decreased absorption of nutrients, because most of the small intestine is bypassed in the new gastrointestinal tract.

Biliopancreatic limb

FIGURE 25-4 Biliopancreatic diversion with duodenal switch.

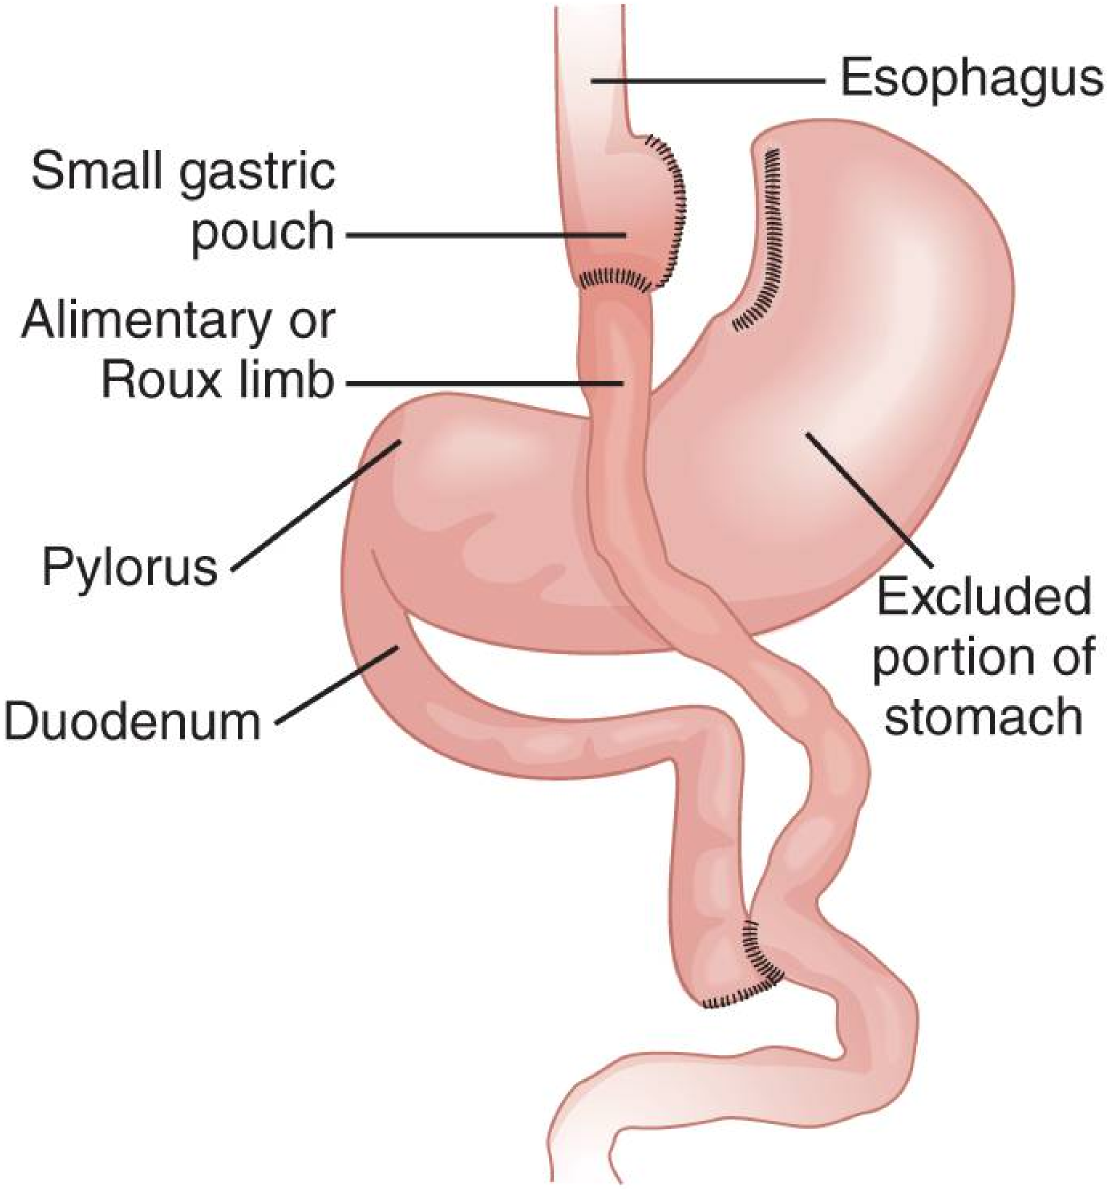
© Jones & Bartlett Learning.

Description

Unlike the LAGB, VBG, and sleeve gastrectomy, the BPD/DS can be performed as either open abdominal surgery or laparoscopic surgery. The lower two-thirds of the stomach is removed and the remaining, smaller upper portion of the stomach is reattached to the ileum. The risk of death with this procedure is 1 in 200, and the procedure is not reversible.

Roux-en-Y

Roux-en-Y gastric bypass, one type of gastric surgery, is the most common type of bariatric procedure and considered the gold standard **FIGURE 25-5**. Much like the BPD/DS, the Roux-en-Y is a two-part procedure that can be performed as either open abdominal surgery or laparoscopic surgery. During this surgery, the stomach, which can normally hold approximately 6 cups (1,420 g) of food, is reduced to a holding volume of approximately 30 mL, or roughly the size of a walnut. Next, the small intestines are divided, and the jejunum is connected to a small hole in the stomach pouch. Roux-en-Y is not a reversible procedure.



Esophagus
Small gastric pouch
Alimentary or Roux limb
Pylorus
Duodenum
Excluded portion of stomach

Description

Intragastric Balloon

The intragastric balloon is a temporary nonsurgical procedure that involves placing a removable silicone balloon filled with 500 to 750 mL of saline in the patient's stomach by endoscopy **FIGURE 25-6**. The balloon helps achieve weight loss by taking up space in the stomach and restricting food intake. The balloon can remain in place for as long as 6 months. This procedure is often an option for patients with a BMI between 30 and 40 kg/m^2. Risks associated with this procedure include overinflation of the balloon, acute pancreatitis, ulcerations leading to gastrointestinal bleeding, and sudden deflation of the balloon leading to a gastrointestinal blockage.

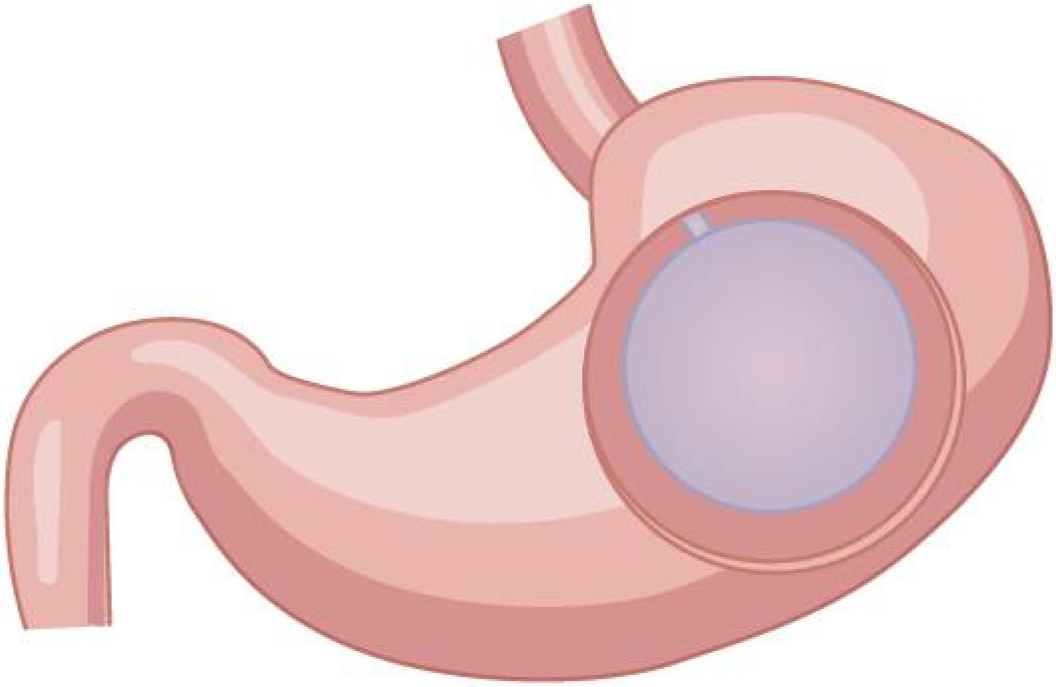

FIGURE 25-6 Intragastric balloon.

© Jones & Bartlett Learning.

Complications of Bariatric Procedures

Complications of bariatric procedures that may require intervention in the form of emergency medical services (EMS) or CCT are divided into early and late complications. Early complications are those that occur within the first month after the procedure, such as deep vein thrombosis, pulmonary embolism, wound infection, sepsis, and gastrointestinal bleeding. These procedures also carry the risk of a stomach or bowel leak from a staple line or anastomosis. With gastric banding, patients can develop an obstruction at the site of the banding.

Late complications occur more than 1 month after the procedure. With all of the bariatric procedures, patients can develop obstructions from strictures, hernias, or hardware complications. Gallstones frequently form after the patient experiences a considerable weight loss. Indeed, they are such a frequent complication of bariatric procedures that the gallbladder is often removed prophylactically as part of the initial operation. Gastric bypass also carries a significant risk of development of ulcers near the area where the stomach and the jejunum are joined. With the banding procedure, a hardware malfunction may develop that results in symptoms of a leak, infection, or obstruction. Thus, undifferentiated abdominal pain is a common 9-1-1 complaint among bariatric patients.

Other specific procedural complications include band erosion, in which the band grows into the stomach and must be permanently removed. Symptoms of this condition include increased hunger and weight gain.

Band intolerance occurs when the body responds to the band as a foreign object, necessitating its removal. Symptoms associated with this complication include excessive vomiting and continuous abdominal and/or epigastric discomfort.

If the lower part of the stomach “slips” through the band, forming a larger pouch above the band, then the complication known as band slippage has occurred. Treatment may include removal of fluid from the band through the port, followed by evaluation of the patient to determine whether the lower portion of the stomach has returned to its previous position. Surgical repair may be required. Symptoms of band slippage include vomiting and reflux.

Port flip/inversion or dislodgment is the most common port-related complication. Port inversion or dislodgment occurs when the port rotates or “flips over.” Port dislocation occurs when the port moves from the original placement location. Both of these complications require a simple surgical repair under local anesthesia.

General Management Considerations for Bariatric Patients

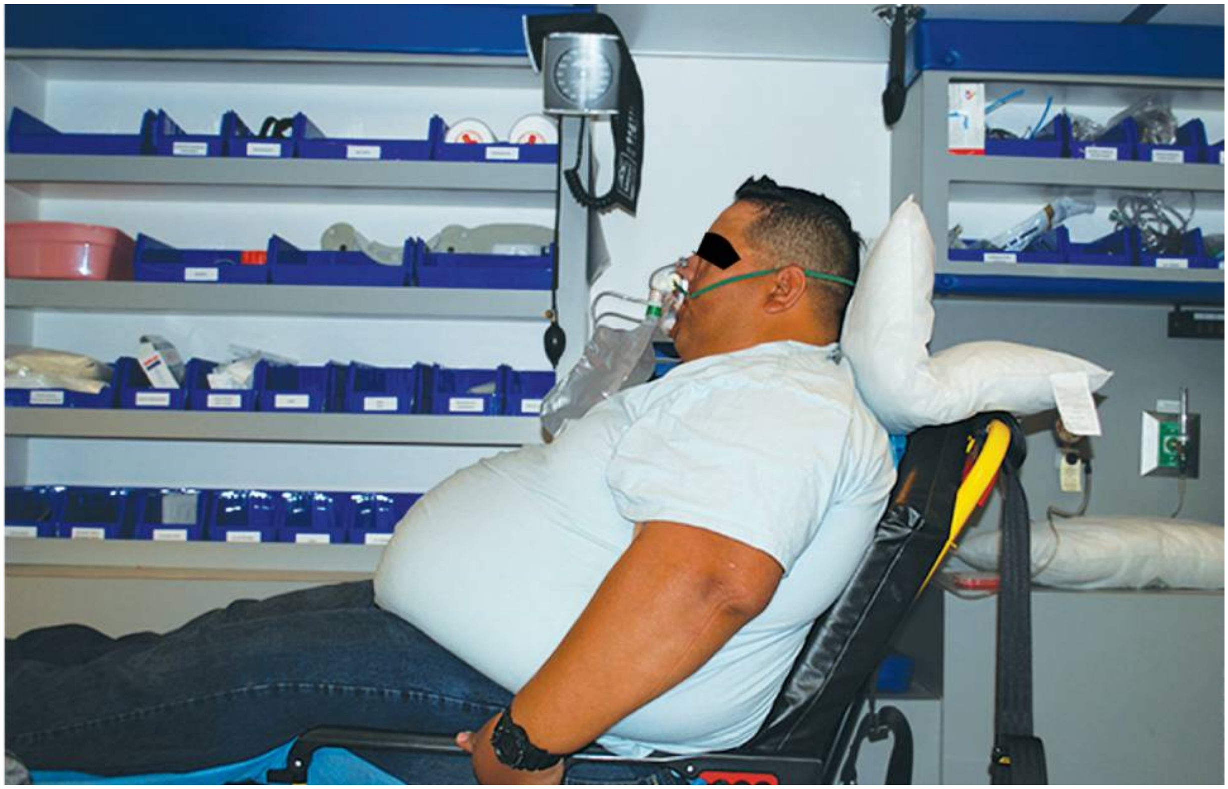
Complications also may occur when bariatric procedures are performed as open abdominal surgery. They include the following conditions:

- Significant blood loss
- Possible need for transfusion
- Allergic reaction to medications
- Anesthetic complications
- Myocardial infarction
- Stroke
- Renal failure
- Pneumonia
- Urinary tract infection
- Deep vein thrombosis
- Sepsis

Airway Management

In patients with morbid obesity or those who have undergone bariatric surgery, both oxygen consumption and carbon dioxide production are increased. As a person's obesity increases, their metabolic demands increase, as there is more tissue that needs to be oxygenated. These changes reflect the increased workload placed on the tissues and the presence of excess fat. The lungs do not proportionally grow in size, resulting in diminished lung capacity. Additionally, fat around the chest wall increases the effort needed to breathe, and the weight of the abdominal tissue restricts movement of the diaphragm, resulting in a rapid and shallow breathing pattern and decreased lung capacity. Bariatric patients also have increased breathing difficulty when in the supine position and have a higher incidence of sleep apnea, snoring, and hypercapnia—the hallmark signs of **Pickwickian syndrome**. Bariatric patients will desaturate faster than patients with an ideal body weight (IBW), which means CCTPs must monitor them more closely during transport and will have a shorter time period to implement interventions if they become hypoxic.

Preparation and anticipation are paramount when moving the bariatric patient between facilities. A significant consideration in patient management is ensuring the CCT team has all the needed equipment and skills to manage the airway in the less-than-ideal setting. Whenever possible, the team should transport the patient in the semi-Fowler position or the ramped position **FIGURE 25-7**, rather than the supine position. The team should also make sure they have ready access to noninvasive airway modalities, including high-flow oxygen via nasal cannula in conjunction with a nonrebreathing mask or a continuous positive airway pressure (CPAP) device. Planning includes ensuring multiple oxygen delivery ports and regulators are available in the transport vehicle.



[redacted]

FIGURE 25-7 The bariatric patient should be transported in the semi-Fowler position or the ramped position.

Courtesy of Dr. Darren A. Braude.

Intubation equipment must be ready, should the need to intubate the patient arise during transport. The process of intubating the bariatric patient is the same as it is for the patient with IBW; however, CCTPs must be prepared for several possible complications:

- The patient will desaturate more rapidly.
- Placing the patient in the sniffing position may not adequately align the fields of view, allowing the CCTP to visualize the vocal cords.
- The medication dosages for a rapid sequence intubation (RSI) may be different.

Research has shown that even in the ideal setting of an operating room, intubation of bariatric patients is significantly more difficult or may require the use of additional airway adjuncts. Intubation success rates decrease by more than 10% in bariatric patients as compared to patients without obesity.

Oxygen consumption rises sharply in bariatric patients during exercise or movement, compared with patients who do not have obesity. This increase in oxygen consumption has implications for the CCTP. Specifically, it may necessitate the use of a full main oxygen cylinder or the inclusion of additional oxygen cylinders on the transport unit, depending on the patient and the length of transport or time spent on the stretcher. One of the responsibilities of the transport team is to ensure there is enough oxygen available for the transport. The necessary calculations are based on Boyle’s law, which is described in Chapter 4, *Aircraft Fundamentals and Flight Physiology*.

In the CCTP setting, it is expected that many patients will be ventilator dependent. The optimal tidal volume in the bariatric patient is between 6 and 8 mL/kg of IBW, with attention to associated positive end-expiratory pressure to avoid atelectasis. Increased tidal volume has not been shown to be beneficial in bariatric patients. Calculation of tidal volume is discussed in Chapter 7, *Ventilation*.

Pharmacology

Many medications carried by transport units are weight based. Recall that IBW is calculated as follows:

- Males (kg): 50 ± (2.3 times patient’s height in inches over 5 feet)
- Females (kg): 45.5 ± (2.3 times patient’s height in inches over 5 feet)

Unfortunately, use of patients’ IBW to calculate dosages tends to cause underdosing of bariatric patients, and using their actual body weight (ABW), if it is accurately known, tends to cause overdosing. To address these problems, an adjustment factor (usually 40%) is often used to estimate the proportion of adipose tissue that distributes a given medication. In situations where the patient’s ABW is less than IBW, dosing should be based on ABW. If the ABW is greater than 125% of IBW, an adjusted body weight (AjBW) should be used. For all other patients, the IBW should be used for dose calculations. For AjBW, the following calculation can be used:

$$\text{AjBW} = \text{IBW} + 0.4(\text{ABW} - \text{IBW})$$

This calculation is especially important when transporting patients who may require intubation.

Dosing of succinylcholine, a neuromuscular blocker, is based on the patient’s ABW, whereas dosing of rocuronium is based on the patient’s IBW. Of the common induction agents, etomidate’s dosing is based on ABW, whereas ketamine’s is based on lean body mass. Of the agents commonly used to maintain analgesia and sedation of the intubated patient, dosing of fentanyl and ketamine is based on lean body mass, whereas dosing of midazolam and propofol is based on IBW.

Lean Body Mass

The patient's body composition, not just weight, is an important consideration when calculating medication doses for bariatric patients. In bariatric patients, the excess adipose weight is accompanied by a 20% to 40% increase in lean body weight. Because increased lean body weight correlates to increased drug clearance (the body's ability to metabolize and excrete a drug), drug clearance is significantly increased in patients with obesity.

Another important insight in properly dosing bariatric patients is that increased cardiac output results in more blood flow through the kidneys, resulting in quicker clearance of medications from the body. A patient with a greater body mass may require higher dosages to obtain a therapeutic level and redosing to maintain this level. Additionally, if the medication is fat soluble, a larger dose may be required, as the drug will be absorbed by the fat cells. The medication will be released slowly, potentially producing a longer-lasting effect.

Dispatch Procedures

The call intake process is crucial in initiating the bariatric transport process. The dispatch center or call center should have a detailed protocol for receiving the bariatric transport request. Training for dispatch personnel should include a standardized protocol for gathering information pertinent to the call type, whether it is a prehospital request or an interfacility transport.

Part of the call screening process should include questions about the patient's height and weight. This information is used to calculate the patient's BMI. The BMI can then be used to determine which resources are appropriate, based on the transport agency's definition. The transport agency must educate personnel in the facilities it serves about the criteria for use of the bariatric truck and balance this information against the desires of both the crews and facility staff. Having objective criteria in place in advance will aid in this endeavor.

Underestimation of the patient's weight places both CCTPs and the patient at risk for injury. Specifically designed scales for these patients can help ensure providers have an accurate knowledge of the patient's weight **FIGURE 25-8**. All too often, however, estimation is often "guesstimation," as many people are simply poor at estimating both height and weight, especially when the patient is supine. Providers should become familiar with methods to quickly determine BMI. The standard way is to multiply the patient's weight in kilograms by the patient's height in meters squared (kg × m^2). Another method is to measure the circumference of the patient's upper arm and the patient's height and to compare these measurements to the values shown in **TABLE 25-2**. Research has shown that this method can estimate the bariatric patient's weight within 15% of the actual weight 90% of the time.

Description

Other patient-specific questions that need to be asked of the sending facility include the following:

- What is the patient’s acuity level?
- What is the reason for transport?
- Does the patient have specific needs during the transport (eg, ventilator support and the need for pain medication or repositioning)?
- What is the patient’s mobility level? Is the patient able to assist with movement from bed to stretcher?

Questions pertaining to operational issues with bariatric patients include the following:

- How long will the transport take?
- Are stairs or ramps present at both the sending and receiving facilities?
- Are the doors capable of allowing egress of the stretcher?
- Do both the sending and receiving facilities have mechanical lift devices to aid in the movement of the patient? If not, are sufficient personnel available to assist in this process at each facility?

Questions pertaining to the receiving facility include the following:

- Are they expecting a bariatric patient?
- Do they have the resources to receive and manage the bariatric patient?

One of the issues faced by transport units is lack of readiness on the part of receiving hospitals to accept bariatric patients in both the emergent and interfacility settings. This lack of preparation is often in part due to a lack of information from either the sending facility, the transfer center, or the transporting unit, depending on the process. To facilitate a smooth transfer, the receiving facility should be advised of not only the patient's weight, but also height and, when possible, abdominal girth, so as to ensure they have the necessary resources for addressing the patient's medical needs.

The diagnostic needs of the patient with obesity should be considered when selecting a receiving facility. Scan tables for computed tomography (CT) have typically been able to accommodate a higher weight than magnetic resonance imaging (MRI) tables, with CT tables typically rated to 200 kg (441 pounds) and MRI tables rated to 150 kg (331 pounds). Open MRI scanners can accommodate up to 250 kg (551 pounds), but the quality of the scan may be diminished. With the CT table, the patient's abdominal circumference can also be a limiting factor: The diameter of the CT scanner's aperture is approximately 75 to 85 cm (30 to 33 inches). Given the ever-increasing prevalence of obesity, CCTPs should consider this additional dimension when caring for bariatric patients and should not focus only on body mass. This information should be available from radiology staff; alternatively, a simple tape measure may be enough to prevent a wasted journey to the CT scanner.

When scheduling the bariatric transport, the CCTP must be aware that the time on task will be significantly increased. Operationally, the CCTP must be prepared for this extended duration and the deleterious effects it may have on the transport service's system-wide performance. Another negative impact on system unit-hour utilization will be that additional resources may be required, further affecting the system's resources and response times. Given these factors, it is recommended that whenever a request for a bariatric transport is received, the agency makes every effort to schedule the transport during a time of low call volume.

One consideration is whether the transport service maintains a staffed bariatric unit 24 hours per day or whether it must recall a crew for the transport. Additionally, what is the crew configuration for bariatric transports: two providers, three providers, or more? Will the call require extra resources?

Moving Bariatric Patients

Although vast numbers of specialty moving devices for bariatric patients are employed within treatment facilities as well as in the prehospital environment, it is important to focus on the mission of the specialty-care transport unit. Adding an excessive amount of space-consuming equipment to an ambulance could be counterproductive, so it is important to include only the essential equipment. Two basic moves are unavoidable and must be planned for:

- Moving the patient from the facility bed, chair, or table to the ambulance stretcher, and doing the reverse at the destination
- Loading the patient into the ambulance, and removing the patient at the destination

Several types of equipment should be considered for the transport of bariatric patients. Some devices best used for the first phase of transporting a bariatric patient (ie, facility to stretcher, and vice versa) are described next.

Slide Boards

A slide board is a basic device that is specifically used when movement of the patient from one level surface to another surface of similar height is indicated, typically from the bed to the treatment table to the ambulance stretcher. Its purpose and the common need for this type of movement means that some sort of slide board is typically readily available in most facilities. Such boards are simple and inexpensive and allow for a reduction of friction. A slide board should be used only under bed linens; it should not be in direct contact with the patient's skin. This low-tech device has multiple handles and can be used by several health care providers simultaneously to minimize the weight each provider is responsible for.

Slide boards come in many variations, such as boards that are foldable and boards with built-in rollers **FIGURE 25-9**. They are typically made of plastic but may also be made of wood. These devices can often be stored in exterior cabinets or under ambulance bench seats. Because of its one-piece construction, a slide board is easily decontaminated.

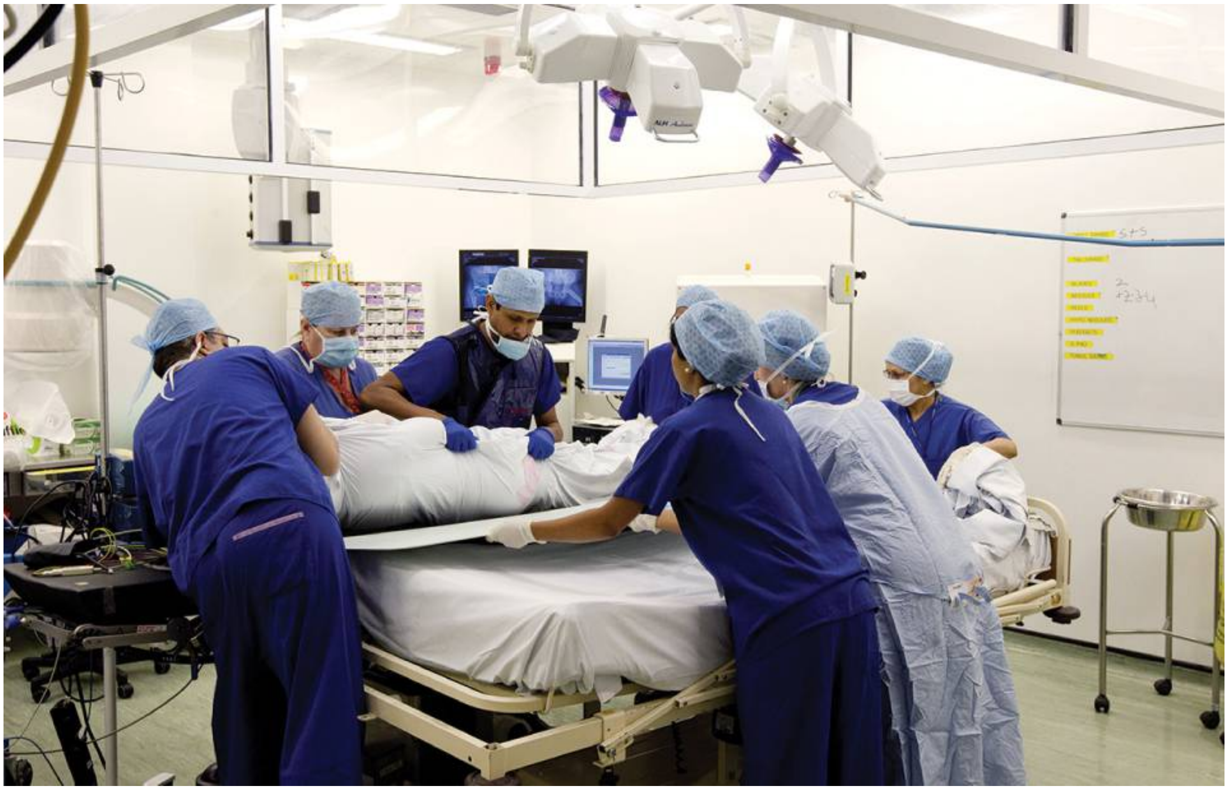

FIGURE 25-9 Slide boards are used to move a patient from one level surface to another.

© Mark Thomas/Science Source.

Disposable, plastic transfer sheets may also be carried in the ambulance, or even on the back of the ambulance stretcher for a simple deployment. Although a plastic transfer sheet might not be as effective as a rigid device, the underlying principle for its use is the same.

Hydraulic and Mechanical Lift Devices

Because of their size and weight, hydraulic and mechanical lift devices are not typically carried on a standard ambulance. Rather, this equipment is most often seen in hospitals, surgical centers, skilled nursing facilities, and rehabilitation facilities. Such lifts use a harness or sling that is often positioned under the patient and connected to a manual or electric-powered mechanical or hydraulic arm **FIGURE 25-10**. The patient can be raised from a bed, a wheelchair, or even the floor and wheeled to the desired location, such as the ambulance stretcher. Before making contact with the stretcher, the patient can be properly positioned and adjusted for comfort. Because of the potential danger when using this equipment, a hydraulic and mechanical lift device should be operated only by those who are properly trained in its use.

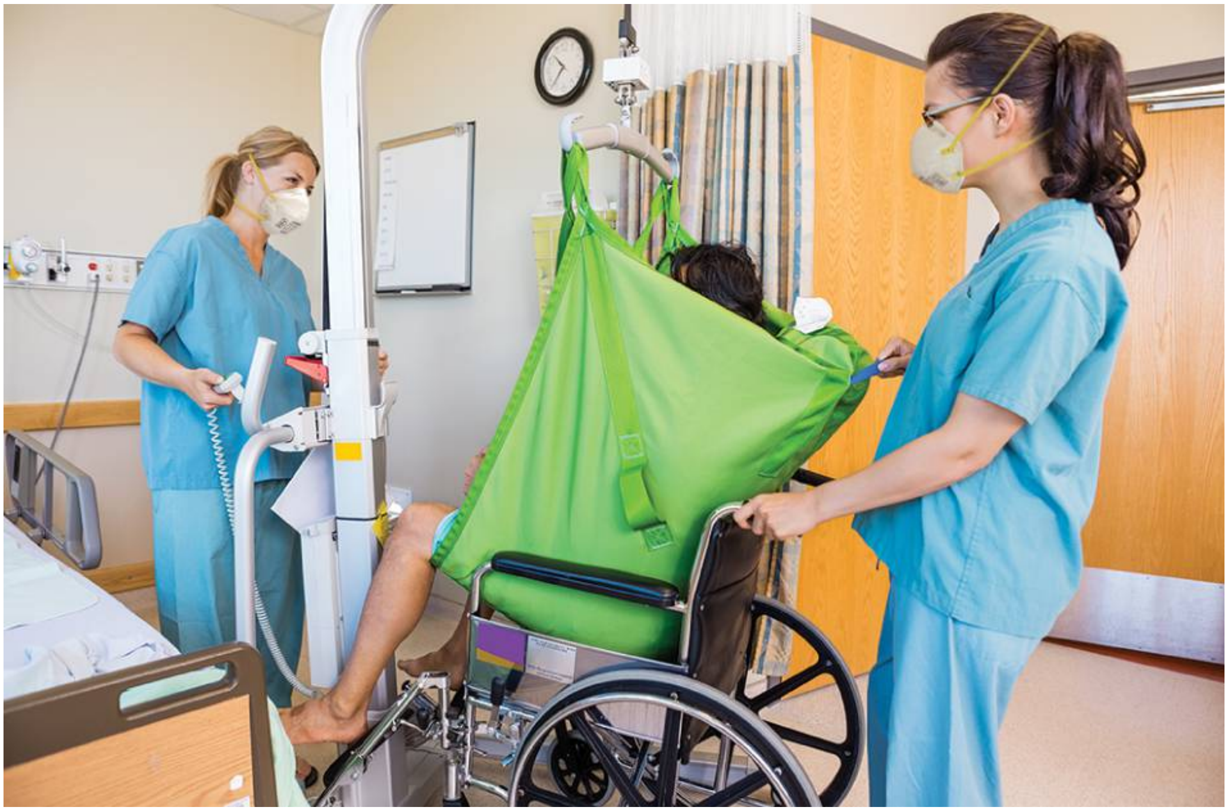

FIGURE 25-10 Hoyer lift.

Some hospitals have installed overhead lift systems in the ambulance bays to facilitate movement of bariatric patients. Use of these devices must be coordinated with hospital staff to ensure trained personnel are available to operate the devices **FIGURE 25-11**.

FIGURE 25-11 An overhead lift system for bariatric patients installed in a hospital's ambulance bay.

Air Transfer Mats

Air transfer mats work similarly to slide boards, in that they are used to laterally transfer patients, regardless of their size, from one level surface to another at a similar height. These mats are typically constructed from vinyl or plastic covered in either a fabric or disposable plastic cover and connect to a compressor that resembles a small canister vacuum **FIGURE 25-12**. After the compressor is activated, the mat fills with air that passes through the perforated underside, making laterally sliding even the largest patient much smoother. Air transfer mats often come equipped with straps or multiple handles, allowing several providers to slide the patient on the device from one bed to the other level surface. These devices are less commonly used, and might not be as simple to store on a standard ambulance.

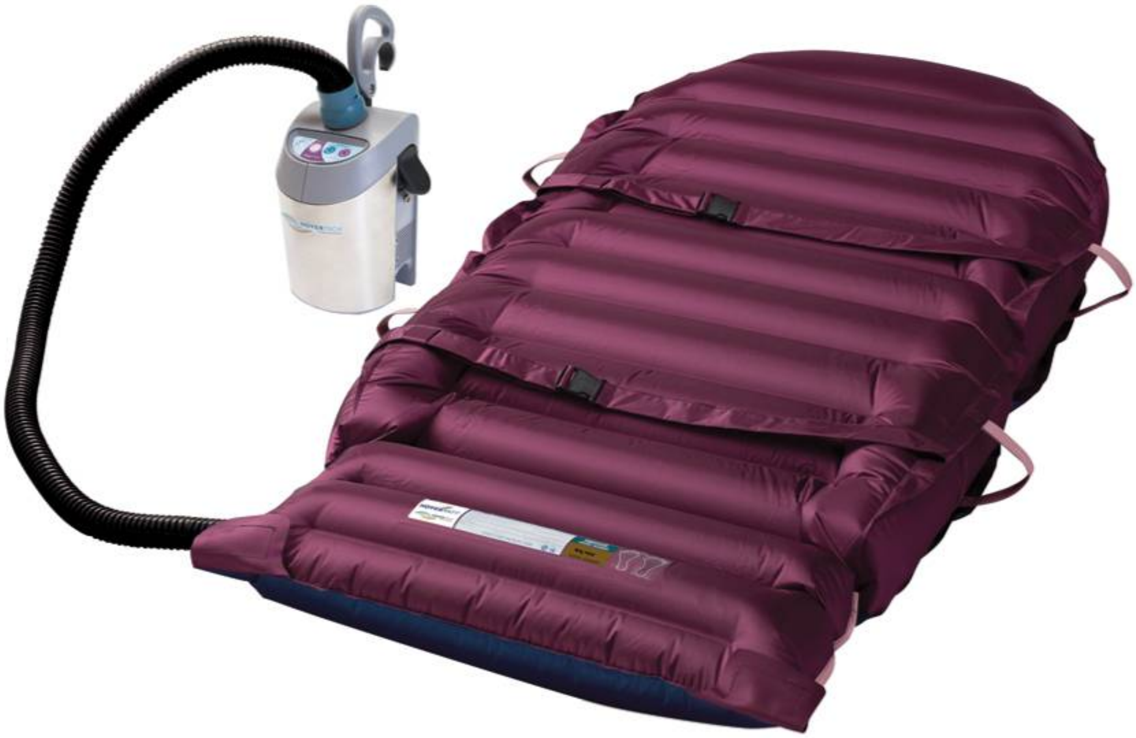

FIGURE 25-12 An air transfer mat.

Stretchers

For the second phase of the transport of the bariatric patient (ie, loading the patient into the ambulance and then unloading the patient at the destination facility), the medical transportation service must consider which type and manufacturer of commercially available bariatric ambulance stretcher it will employ. The two most commonly used stretcher manufacturers, Ferno and Stryker, produce both regular and bariatric-specialty stretchers. The bariatric versions closely resemble the standard models, with the intent of being similarly operated; thus, they require minimal extra training for use in organizations that employ both bariatric- and regular-model stretchers. The bariatric models are rated for a higher capacity and size. They are made with stronger construction and are considerably wider to ensure the patient's comfort. They come with a variety of (sometimes optional) features, such as larger, locking wheels; thicker mattresses; additional loading handles; longer belts; and a “tow package” (ie, a cable that allows the stretcher to be loaded into the ambulance via an electric winch when ramps are also used). Some bariatric ambulance stretchers have battery-powered systems that raise and lower the patient, reducing the need for the providers to do so. The addition of a low-friction slide device will also assist in the lateral movement of the large patient **FIGURE 25-13**.

Ramp and Winch Systems

In addition to the bariatric ambulance stretcher, many services have deployed a ramp and winch system in specific vehicles designated for the transportation of bariatric patients. These systems avoid the need for providers to manually load the bariatric stretcher into the ambulance. When used, the ramps are deployed as pictured in **FIGURE 25-14**. They are connected to the rear patient compartment of the ambulance, typically via a transition plate that is easily secured and removed via heavy-duty thumb screws. The stretcher is pulled into the ambulance by using an electric winch mounted in the ambulance near the front of the patient compartment.

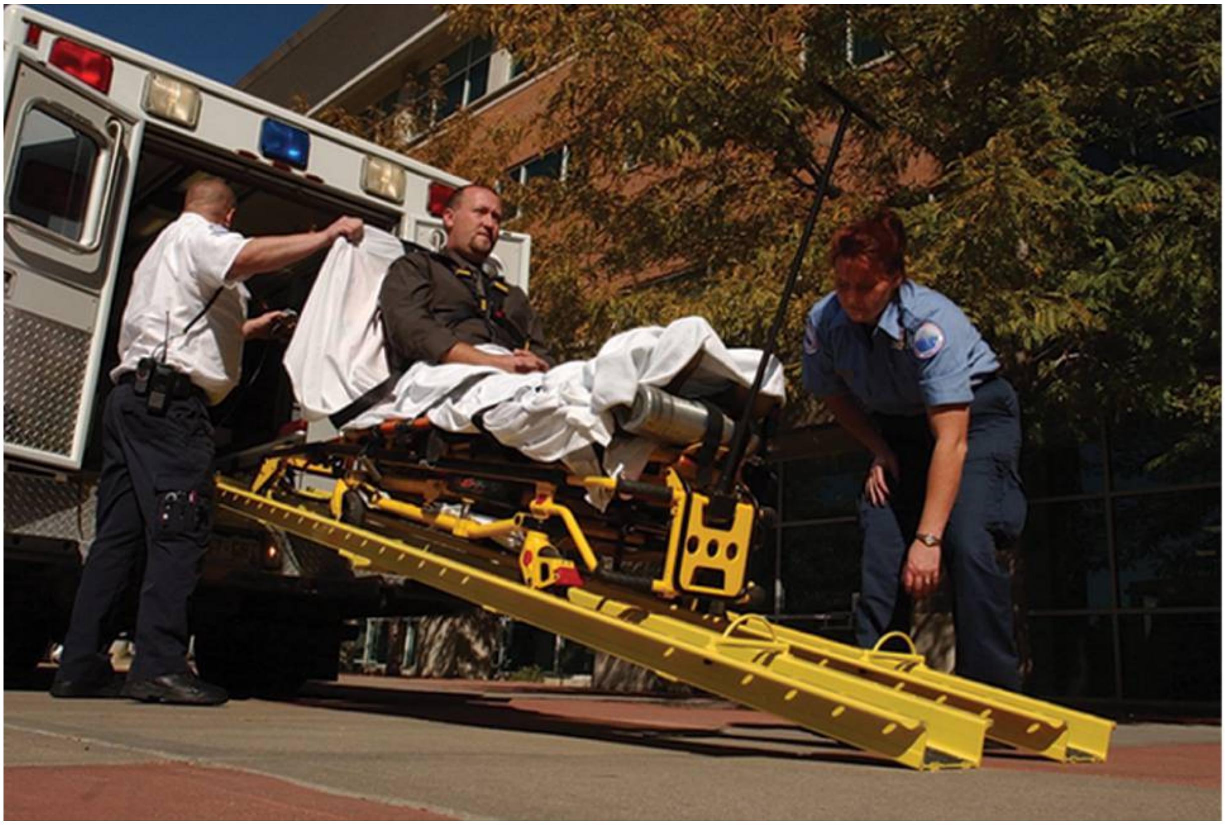

FIGURE 25-14 A crew loading a patient using a ramp and winch system.

All providers operating the bariatric ambulance stretcher, ramps, and other equipment must be specifically trained in their use, because improper usage could lead to harm of the patient or crew members.

Special Considerations With Bariatric Patients

Bariatric patients present the medical transportation industry with some unique problems. As with any other segment of the population, the needs of bariatric patients must be accommodated. Some of these problems are related to medical treatment; others are related to the patients' emotional needs and general customer service matters.

For example, due strictly to their sizes, bariatric patients require special considerations when being prepared for transport. Often, conventional clothing and linens simply do not fit, yet the provider must be committed to ensuring the same dignity and comfort as would be accorded to the patient without obesity. One solution may be to craft specific covers for the bariatric patient when moving in and out of facilities, ensuring that every part of the body is covered and warm. Doing so may require the use of multiple layers of blankets and bed linens. Patients may be unable to comfortably adjust their position on an ambulance stretcher in the same way that smaller patients might. It is best to consider this issue while preparing for transport; at this point, more assistance is typically available to move patients in a way to ensure that they are most comfortable. By comparison, such adjustments may prove extremely challenging during a long-distance trip with only a single provider to attend to the patient. Specific attention must be paid to not only the position the patient wants to be in for comfort, but also the position the patient might need to be in to support the effort to breathe. Bariatric patients may have difficulty breathing unless they are in an upright position.

Another special consideration is that the bariatric patient's body parts often do not fit into the same spaces that a smaller patient's do. Accommodating the bariatric patient might require using less routine methods to ensure comfort, such as strategically placed pillows, rolled blankets, and other aids. In addition, bed-bound bariatric patients often have chronic skin problems such as decubitus ulcers. Providers must manage the severe pain caused by these wounds, change bandages during transport, and after the transport, thoroughly decontaminate the ambulance equipment that came in contact with wound drainage.

Often, the best way to accommodate the bariatric patient's special needs is through proper communication. Such patients, similar to those with other challenges, have likely learned ways to deal with these challenges and can assist providers in helping with moving, positioning, and other transport issues. To this point, it is of utmost importance to protect the patient's dignity and privacy. For example, although additional personnel might be needed to make the patient transfer, these needs should not be publicized. Thus, for a typical interfacility transfer of a bariatric patient, agencies should avoid sending multiple teams of providers into the facility at the same time, causing a spectacle.

Safety during bariatric transports is a paramount concern for both the providers and the patient. Such patients' weight and atypical body shape contribute to an increased risk of injury to both providers and patients during patient handling and movement tasks. Moreover, with the increase in the number of bariatric patients and the trend toward health care providers working longer at an older age, CCTPs' higher likelihood of caring for these patients translates into an increased risk of injury that can have catastrophic outcomes for provider and patient alike.

Many tools exist to reduce the risk of injury, and several states have enacted "no lift" laws that require health care facilities to use mechanical devices to move patients whenever feasible. Such devices include ceiling harnesses, emergency lifting cushions, patient boosters, and motorized wheelchair and bed movers. When these devices are present, it is incumbent upon the transport crew to ensure they are used by properly trained staff. If these devices are unavailable, then it is imperative that adequate personnel be present to facilitate the safe moving of the patient. The proper prehospital equipment must also be available, and CCTPs need to be trained in its use.

Diagnostic Tools

If the proper diagnostic tools are not available during transport of the bariatric patient, medical evaluation and monitoring may be challenging, unreliable, or even impossible. Providers must have the proper sizes of blood pressure (BP) cuffs, airway adjuncts, and intravenous (IV) equipment and any specialized diagnostic tools necessary. A BP cuff that is too small will give a false reading. Standard IV catheters may not be long enough to cannulate a vein in the patient with morbid obesity. Additionally, locating an appropriate vessel will be complicated **FIGURE 25-15**. Even standard pulse oximetry can be difficult because tissue thickness will impede the light waves. CCTPs should make sure other probes, including an earlobe attachment, are available. Another option is to use nasal capnography to monitor respiratory and cardiovascular function during transport.

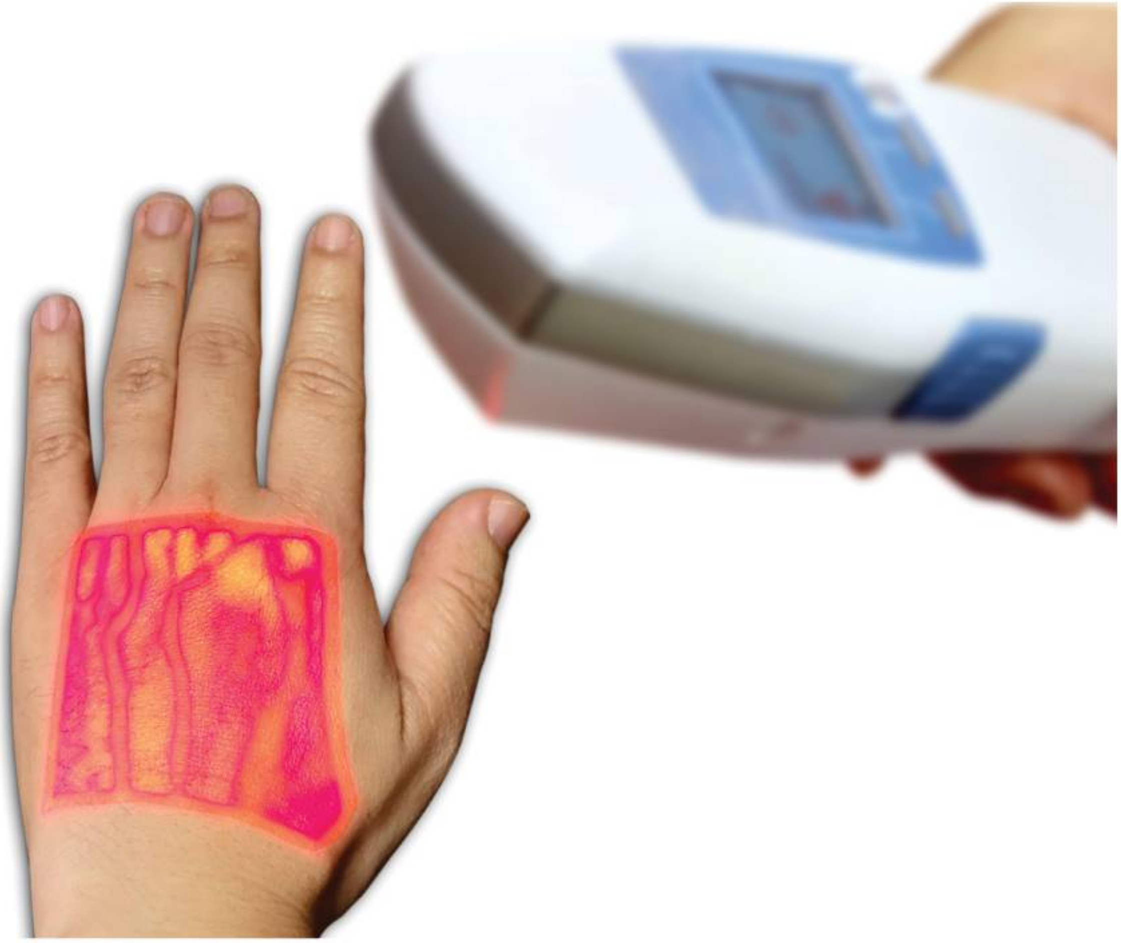

FIGURE 25-15 Using an infrared vein finder may help providers locate an appropriate vessel in the bariatric patient.

© Samunella/Alamy Stock Photo.

Point-of-care ultrasonography (POCUS) in patients with obesity can be challenging. The machine needs to penetrate additional tissue and fat before the ultrasound wave reaches its desired structure and travels back. One problem with using POCUS for these patients is the attenuation. The machine must have enough energy and the necessary hardware and software to compensate for the imperfections introduced by the additional tissue. Such capabilities may not be available with current prehospital devices.

Reimbursement Issues

Because of the intense personnel and equipment requirements, maintaining a bariatric transport program can be expensive and often represents a financial drain on a transport agency. The ability to obtain additional reimbursement beyond that provided under normal billing practices is limited. Most insurance companies, including Medicare and Medicaid programs, do not classify bariatric transport as a specialty care transport, so it is ineligible for a higher reimbursement rate.

Excited Delirium

Excited delirium, also called agitated delirium, is a complex condition that can cause severe morbidity and mortality if not rapidly identified and treated. Although excited delirium has only recently been formally recognized in the medical literature, clinically similar conditions were documented as long ago as the 19th century. Early documented cases came primarily from institutions housing patients with mental illness who demonstrated violent and aggressive behavior. The syndrome was first described by Dr. Luther Bell in 1849. Termed Bell's mania, it was noted to carry a mortality rate of 75%. In 2008, the Council of the American College of Emergency Physicians adopted a resolution to formally recognize excited delirium as a disease entity within emergency medicine, followed in 2009 by a white paper characterizing its clinical presentation, pathophysiology, and treatment. Since then, the biologic basis of excited delirium has become better understood, leading to improvements in diagnosis and treatment of this critical illness.

Delirium has long been recognized as a psychiatric diagnosis. It is described in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*) as an acute disturbance in attention and awareness resulting from another condition such as substance intoxication or toxicologic exposure. Delirium, as described in the *DSM-5*, is not associated with sudden death, distinguishing it from excited delirium. Excited delirium, as a distinct diagnosis, is not included in either the *DSM-5* or the International Classification of Diseases (ICD-9, ICD-10).

The frequency with which excited delirium occurs outside of hospital settings, often involving law enforcement and paramedic restraint of highly agitated individuals, and the wide variety of causes of death issued by medical examiners in suspected excited delirium deaths have made use of the term controversial. In 2021, the American Medical Association (AMA), following a Special Meeting of its House of Delegates, adopted a policy opposing the use of excited delirium as a medical diagnosis until a clear set of diagnostic criteria has been established. Further, it reasserted the need for physician-led medical oversight in out-of-hospital situations deemed medical emergencies. The AMA has emphasized the risk posed by sedative-hypnotic and dissociative drugs when given without an adequate understanding of the patient. The AMA's policy is guided by a concern for the violent policing practices born of institutional racism. By calling for the disuse of this term, the AMA hopes to delegitimize a concept that it believes is often used as a "cover-up" for policing practices that tend to target members of marginalized and minority communities who would be better served by behavioral crisis interventions, such as de-escalation.

The Term *Excited Delirium*

Delirium, as described in the *DSM-5*, often goes unrecognized in hospitalized patients and is associated with adverse outcomes. In all areas of medicine, care of the agitated, violent, or combative patient poses some of the most challenging legal concerns and potential risks to all involved. While acknowledging the current disagreements in terminology, recognition, and actual pathophysiology of this condition, this text continues to use the term *excited delirium*, recognizing that it refers to a legitimate form of delirium that, when untreated or poorly managed, can result in death.

Symptoms of excited delirium include the acute onset of hyperactive, aggressive, and/or combative behavior, often associated with excessive physical strength. Signs include disorientation and altered mental status, tachycardia, tachypnea, heightened pain tolerance, hyperthermia, and metabolic acidosis. Frequently, excited delirium is precipitated by recent use of sympathomimetic or hallucinogenic recreational drugs (cocaine, methamphetamine, phencyclidine [PCP], phenethylamine, or methylenedioxymethamphetamine [MDMA]). Less commonly, excited delirium may occur without drug use in the context of acute decompensated psychiatric illness, such as schizophrenia or bipolar disorder.

As has been portrayed in the media, patients with excited delirium are at significantly increased risk of sudden cardiac death while restrained or in police custody. Deaths have also occurred prior to apprehension by police, during EMS transport, or in the emergency department (ED). Importantly, patients with excited delirium most frequently die within approximately 1 hour of first contact with police or EMS. The reported mortality rates for this condition are as high as 16.5%. Even with timely and appropriate treatment, mortality remains high; nevertheless, early, targeted treatment may greatly improve outcomes.

Risk Factors

Several risk factors have been identified that appear to predispose an individual to developing excited delirium. Demographically, excited delirium typically occurs in men in their 30s, commonly in the setting of cocaine use, but also frequently involving methamphetamine, PCP, or phenylethylamine. In addition, recreational drugs sold in pill form under the street name “Molly” (often a phenylethylamine variant such as 2CE or 2CT7) have been identified in excited delirium cases. Individuals who chronically use stimulants appear to have a higher risk for experiencing excited delirium, although this syndrome typically occurs after an acute binge. Additionally, underlying psychiatric disorders may be seen in patients with excited delirium, most commonly schizophrenia or bipolar disorder.

One theory for the link between stimulant drug use and psychiatric disease, as these factors relate to excited delirium, is increased activation of the dopamine pathway. This neurotransmitter is commonly implicated in the psychotic features of both conditions. While neurochemical similarities between stimulant use and psychiatric disease have been identified, they do not account for the difference in risk of sudden cardiac death noted between patients with excited delirium and those with underlying schizophrenia.

Pathophysiology

Excited delirium is thought to be the result of increased catecholamine levels in the brain. The pathophysiology of excited delirium has been studied most extensively in cocaine users. Stimulant use, including cocaine use, is known to alter brain neurochemistry and is an independent risk factor for the development of excited delirium. Cocaine produces intoxication by preventing the removal of dopamine from the synaptic cleft between adjacent neurons by dopamine transporter (DT) proteins, thereby increasing the synaptic concentration of dopamine. In individuals who chronically use cocaine, the repeated exposure to cocaine results in up-regulation of DT proteins in response to the long-term elevation in synaptic dopamine levels. In essence, the body attempts to autoregulate the chronically elevated dopamine levels associated with repeated cocaine exposure by increasing the concentration of proteins that eliminate dopamine from the synapse.

Autopsy studies examining brain tissue in patients believed to have died from excited delirium due to cocaine use have been compared with brain tissues taken from patients without excited delirium who were also intoxicated with cocaine at the time of death. These postmortem studies demonstrate that patients with cocaine intoxication and excited delirium show a lower number of DT proteins relative to patients who died of cocaine intoxication without excited delirium. These findings suggest that the brains of patients with excited delirium show distinct chemical differences: They are unable to clear dopamine from the synaptic cleft (due to decreased numbers of DT proteins), resulting in very high synaptic levels of dopamine.

Dopamine is a fundamental neurotransmitter, playing important roles in executive function, impulsivity, sensory perception, and key physiologic parameters (eg, heart rate, BP, and temperature regulation). Elevated dopamine levels have long been linked to the perceptual disturbances seen in schizophrenia, including hallucinations and paranoid delusions. Early antipsychotic agents such as haloperidol and chlorpromazine, which have been shown to improve the symptoms of schizophrenia, work by blocking dopamine receptors in the brain. Dopamine is also known to affect renal function and alter BP through multiple mechanisms, including alteration of the renal renin–angiotensin pathway and modulation of sympathetic tone, which impacts vascular smooth muscle as well as heart rate.

The clinical manifestation of excited delirium is a hypermetabolic state, which increases both consumption of energy and production of metabolic wastes. The sympathomimetic effects associated with excited delirium, including tachycardia, hypertension, and elevated temperature, increase the body's metabolic oxygen consumption. On a cellular level, oxygen supply–demand mismatch occurs, and energy generation transitions from aerobic metabolism to anaerobic metabolism. This not only decreases the efficiency of energy (ie, adenosine triphosphate) production, but also leads to production of excessive amounts of lactic acid. Accumulation of lactic acid, in turn, leads to a significant metabolic acidosis. In an attempt to compensate for the declining pH of the blood, the body increases the respiratory minute ventilation to increase exhalation of carbon dioxide and neutralize the lactic acid via its conversion to carbon dioxide and water. **Kussmaul respiration** is a typical respiratory pattern seen in patients with metabolic acidosis; it is characterized by a high respiratory rate and high tidal volume, leading to increased minute ventilation. Laboratory abnormalities in patients with lactic acidosis include an elevated anion gap and decreased bicarbonate levels (corresponding to carbon dioxide levels on a basic metabolic profile). As the metabolic acidosis becomes more profound, elevated potassium levels cause cardiac conduction problems, leading to arrhythmias and eventually sudden cardiovascular collapse. In cases of cardiac arrest, brady-asystolic cardiac arrest and pulseless electrical activity are the predominant terminal cardiac rhythms.

Psychomotor agitation is another hallmark sign of excited delirium. Elevations in cerebral dopamine levels lead to restlessness, paranoia, disorientation, decreased attention span, and hallucinations. These symptoms are similar to those observed in patients with mania but can wax and wane in intensity. When they are drug induced, their presence supports a formal diagnosis of delirium (ie, acute confusion, hallucinations, and disorientation that is rapid in onset and may fluctuate in intensity).

Similarly, the peripheral musculature (via a mechanism that is not fully understood) shows a hyperactive state in excited delirium. Repetitive muscle contractions manifest as pacing, constantly moving extremities, darting eyes, or an inability to sit still. When physically restrained, patients often struggle violently against their restraints until sedative medications are administered.

The constant muscle contractions lead to an elevation in body temperature, further worsening the metabolic demands on the body. This elevation in temperature and hypermetabolic state can lead to muscle breakdown, triggering the release of intracellular potassium and renal toxins, including myoglobin. As myoglobin levels in the blood increase (myoglobinemia), the patient develops rhabdomyolysis, which directly injures the kidney. Acute tubular necrosis develops as the excess myoglobin damages the nephrons of the kidneys and the patient’s blood urea nitrogen (BUN) and creatinine levels rapidly increase. Renal failure has a multifactorial etiology in these patients, demonstrating both a prerenal component from hypovolemia and intrarenal damage from the direct toxic effects of the myoglobin. The net increase in extracellular potassium and waste products places the patient at high risk for cardiac dysrhythmias and death.

Signs and Symptoms

As mentioned previously, excited delirium is a relatively new diagnosis. It is easily recognized as tachycardia, hypertension, psychomotor agitation, and diaphoresis. Patients with excited delirium are often aggressive or combative and may exhibit unanticipated strength with impaired pain perception; as such, they may resist painful stimuli and physical restraint attempts.

Delirium is manifested by hallucinations, paranoia, and disorganized behavior and thought processes. Frequently described manifestations include severe agitation, violent behavior often resulting in damage to property; a lack of awareness of one’s surroundings, including disrobing in public; and verbal responses to internal stimuli. These behaviors often result in calls for a law enforcement response, which may be the initial patient contact. In these situations, less lethal methods to take an individual into custody, including use of pepper spray and conducted electrical weapons (eg, TASER device), are frequently ineffective.

Medical conditions other than excited delirium should be included in a provider's differential diagnosis for an agitated patient with altered mental status **TABLE 25-3**. It can be difficult to differentiate excited delirium from other diagnoses without a thorough evaluation. Unfortunately, such an evaluation may be nearly impossible to perform prior to the administration of sedative medications due to the risk of injury to the patient and health care providers. Often, only a very limited history can be obtained due to the patient's altered mental status and combative behavior. When possible, obtaining a 12-lead electrocardiogram (ECG) can be useful to identify arrhythmias, QTc interval prolongation, QRS complex widening, cardiac ischemia, and evidence of **hyperkalemia**.

TABLE 25-3 **Differential Diagnosis: Excited Delirium**

Possible Condition[a]	Pertinent Diagnostic Evaluations
Alcohol intoxication/withdrawal, Wernicke encephalopathy	Ethyl alcohol level, thiamine level
Anticholinergic toxicity	Medication history, physical exam (patient will exhibit hypothermia, dilated pupils, dry skin and mucous membranes, flushed skin, and agitation or delirium), core temperature, bladder scan for urinary retention, CK level, basic metabolic panel, acetaminophen and salicylate levels (possible co-ingestion with nighttime formulation medications), ECG

Possible Condition[a]	Pertinent Diagnostic Evaluations
Head injury/central nervous system lesion (consider spinal motion restriction and imaging if trauma is suspected)	Computed tomography brain noncontrast imaging; may require magnetic resonance imaging in the subacute setting
Heatstroke	History, core temperature, renal function, CK level
Hypoglycemia	Fingerstick blood glucose level
Hyponatremia	Serum chemistry
Hypoxia/hypercapnia	Pulse oximetry, venous/arterial blood gas analysis
Infection (encephalitis, meningitis, sepsis)	Physical exam, chest radiograph, urinalysis, blood cultures, lumbar puncture
Neuroleptic malignant syndrome	Medication history, muscular rigidity or tremor, core temperature, CK level, pH, lactate level, ECG, comprehensive metabolic panel
Psychiatric emergency	History and physical exam, evaluation for any precipitating factors: infection, drug ingestion (including psychiatric and recreational), ethyl alcohol, TSH
Seizure/postictal state	Past medical and medication history, lactate level, CK level, pH, electroencephalography, drug screen
Serotonin syndrome	Medication history, reflexes (clonus, lower extremity greater than upper), core temperature, CK level, pH, lactate level, ECG
Sympathomimetic toxidrome	History and physical exam (eg, diaphoresis, tachycardia, mydriasis, rotary or vertical nystagmus), drug screen
Thyrotoxicosis	TSH, free thyroxine test, evaluation for any precipitating factors
Uremia/renal failure	BUN, creatinine, electrolytes

Abbreviations: BUN, blood urea nitrogen; CK, creatine kinase; ECG, electrocardiogram; TSH, thyroid-stimulating hormone

[a] With all potential underlying diagnoses, it is imperative to first treat and control the symptoms to avoid potentially fatal deterioration.

© Jones & Bartlett Learning.

Laboratory evaluation of a patient with excited delirium typically reveals a severe anion gap metabolic acidosis, primarily due to elevated lactic acid levels from the anaerobic metabolic state. Additionally, patients may have a nonspecific leukocytosis, which is generally not helpful in narrowing the differential diagnosis. Severe tachycardia can lead to coronary underperfusion, resulting in cardiac-demand ischemia and subsequently elevated troponin levels. **Rhabdomyolysis** is frequently seen with excited delirium, evidenced by elevated creatine kinase (CK) levels, myoglobinuria, hyperkalemia, and eventual acute renal failure.

Treatment

Excited delirium is a dangerous and often fatal condition that requires prompt diagnosis and careful management to minimize morbidity and mortality. Given the relatively recent formal recognition of this syndrome in emergency medicine, clinical management has historically been largely anecdotal, with treatment algorithms based on ED protocols and expert opinion. In recent years, however, evidence-based guidelines have increasingly been adopted. The primary goals in treating a patient with excited delirium are to protect the patient and providers from injury while maintaining patient dignity, reduce psychomotor agitation, perform a detailed physical exam and continuous monitoring of vital signs, establish IV access, and prevent morbidity and mortality.

Initial treatment focuses on reducing the patient's agitation through the use of verbal de-escalation techniques. If these tactics are ineffective, as may occur with patients demonstrating extreme aggression, agitation, and unexpected physical strength, rapidly administering sedative medications, correcting hypovolemia with IV volume resuscitation, initiating specific therapies targeted at metabolic abnormalities, and controlling environmental conditions that increase mortality have been shown to improve outcomes. The National Association of EMS Physicians revised its position statement on excited delirium in 2020 to recommend that treatment include using appropriate verbal and environmental de-escalation techniques, using the least restrictive physical restraints and pharmacologic interventions necessary to facilitate safe patient assessment and transport, and prohibiting dangerous actions such as EMS use of handcuffs, patient transport in the prone position, and maneuvers that constrict the patient’s chest or neck.

Frequently, severe restlessness or combative behavior prevents the establishment of IV access, and pharmacologic sedation must be administered via the intramuscular (IM) route. The most commonly used medications for this purpose include benzodiazepines (eg, midazolam, lorazepam), antipsychotics (eg, droperidol, haloperidol, olanzapine, ziprasidone), and ketamine. Although agents from each of these drug classes have been used effectively, they are characterized by different risk–benefit profiles.

Benzodiazepines are often used as an initial therapy to blunt the sympathomimetic component of the excited delirium, especially when stimulant drug use is present. Midazolam is typically the preferred agent because it has a rapid onset of 3 to 10 minutes, is heat-stable, and can be administered to an adult as a 1-mL injection IM or intranasally via the 5 mg/mL concentration. Lorazepam has slower IM absorption, leading to an onset of sedation in the range of 15 to 30 minutes and peak serum concentration within 3 hours. After IV access has been established, titration of additional benzodiazepines or other medications can be used to maintain adequate sedation. Caution should be used with all benzodiazepines since patients with excited delirium may have also ingested ethanol or other central nervous system (CNS) depressants, a behavior that increases the risk of respiratory depression with even a single dose of sedative medication.

Antipsychotics present an attractive pharmacologic approach to treating excited delirium because they antagonize the dopamine receptor. Unfortunately, first-generation antipsychotics, such as haloperidol and droperidol, may significantly prolong the QTc interval and can lead to extrapyramidal adverse reactions. Haloperidol, a frequently used medication in patients with acute agitation, has an onset of action of approximately 15 to 30 minutes via the IM route. In patients thought to be intoxicated with ethanol, however, antipsychotics may be less likely to potentiate the risk of respiratory depression than benzodiazepines are. Second-generation agents, such as olanzapine, offer less risk of QTc interval prolongation and extrapyramidal side effects compared to first-generation antipsychotics, and can be given via IM or rapidly dissolving tablet. Research is limited on the use of second-generation antipsychotics in patients with excited delirium, and their higher cost may be a barrier to their use in some EMS systems. If antipsychotic medications are required, the CCTP should obtain an ECG to evaluate for QTc interval prolongation and QRS complex widening as soon as possible.

More recently, the dissociative medication ketamine has been successfully used to treat acute agitation in patients with excited delirium. Ketamine, which acts primarily as an *N*-methyl-D-aspartate (NMDA) receptor antagonist, is widely used for procedural sedation in the hospital. Its major benefits include its rapid onset of action (less than 5 minutes), wide therapeutic window, hemodynamic stability, and relative (although not absolute) preservation of respiratory drive and airway reflexes. Ketamine does not antagonize the underlying hyper-dopaminergic state, as antipsychotics do, nor does it blunt the sympathomimetic response, as benzodiazepines do. Additionally, ketamine can cause emergence reactions, hypersalivation, and laryngospasm, which may increase the risk of aspiration. Due to its rapid onset of action, ketamine is effective in quickly achieving adequate sedation with a typical dose of 3 to 5 mg/kg IM, though it may also be effective with a dose as low as 2 mg/kg IM. Rapid sedation will limit physical struggling by the patient and allow prehospital providers to safely perform an assessment and initiate life-saving interventions (eg, IV volume resuscitation, correction of critical cardiac arrhythmias, and treatment of hyperthermia, metabolic acidosis, and hypoxia).

In studies investigating the use of ketamine in patients with excited delirium, intubation rates typically range from 23% to 39% but have been reported to be as high as 63%. Confounding variables such as coadministration of benzodiazepines and lack of hospital provider familiarity with the drug may partly account for the increased intubation rate. Overall, however, patients who receive higher ketamine doses tend to be intubated more frequently. Given this finding, keeping the initial IM dosing to approximately 3 to 5 mg/kg (200 to 300 mg IM for an average adult), with a maximum dose of 400 mg, is appropriate. If the patient has already received another medication, such as a benzodiazepine, an initial ketamine dose of 2 mg/kg IM should be considered. After preliminary sedation has been achieved and IV access has been established, additional benzodiazepines and/or antipsychotics may be required to maintain the sedated state until the patient's vital signs and mental status have improved. Since patients who receive pharmacologic sedation are at increased risk of respiratory depression, high-flow oxygen should be readily available and used to treat hypoxia.

After sedation has been achieved, providers should rapidly evaluate the patient for underlying physiologic disorders that could be driving or exacerbating the delirium. Specific considerations for patients with excited delirium include, but are not limited to, identification and treatment of trauma, hyperthermia, rhabdomyolysis, hyperkalemia, hypoxia, and metabolic acidosis.

With a prolonged state of extreme hyperactivity, patients with excited delirium often become dangerously hyperthermic, and cooling, although controversial, may be required in addition to benzodiazepine therapy. The patient's body temperature should ideally be monitored with a core temperature probe (via esophageal access, Foley bladder catheter, or rectal access), although in most situations it is not practical to do so. While less accurate, temperature should be frequently monitored via a temporal artery, tympanic, oral, or skin thermometer to detect rising body temperature and hyperthermia if core temperature assessment is not possible. Standard treatment for hyperthermia (eg, removal of clothing, misting water over a patient, adding a fan to increase convection and evaporation, ice packs to the axilla and groin) is indicated; this protocol is described in Chapter 19, *Environmental Emergencies*.

The extreme hyperactivity of excited delirium also elevates the risk of muscle breakdown, leading to rhabdomyolysis and hyperkalemia. The treatment of rhabdomyolysis emphasizes aggressive IV volume resuscitation and urine output monitoring to maintain adequate renal perfusion and reduce the risk of kidney damage. Initial treatment is 20 to 30 mL/kg (2 to 3 L) of crystalloid (normal saline or lactated Ringer solution) over the first 30 minutes. After initial fluid boluses have corrected any hypovolemia and restored the patient to a euvolemic state, IV fluids at a rate of 1.5 to 2 times the maintenance rate in the form of an isotonic sodium bicarbonate solution can be considered, because alkalization of the urine may protect the kidneys against further damage from myoglobinuria. The goal of volume resuscitation is to maintain urine output at a rate of 0.5 to 1 mL/kg/h. An ECG finding of hyperacute T waves should prompt standard advanced cardiac life support treatment for hyperkalemia

Interfacility Transport Monitoring

Patients with excited delirium who require transport should be placed on continuous cardiopulmonary monitoring, including ECG and pulse oximetry. End-tidal carbon dioxide ($ETCO_2$) monitoring should also be used, especially if sedative medications have been administered. Respiratory status and cardiac rhythm are the critical vital signs to monitor continuously for changes during transport. In addition, the CCTP should monitor the patient’s body temperature and initiate aggressive cooling interventions in the event of hyperthermia.

If the patient requires physical restraints for transport, the CCTP should use the least restrictive management strategy that allows for safe evaluation and treatment. Providers should be able to quickly remove physical restraints if necessary, and handcuffs or locked restraints should not be used by CCTPs. If handcuffs are required by law enforcement, an officer should accompany the patient and the key should be immediately available at all times. The CCTP should never transport a patient in the prone position, with hands and feet tied together behind the patient’s back (often referred to as “hogtied”), or in a position that constricts the chest or neck. Patients requiring physical restraints and/or pharmacologic sedation should have their airway and the neurovascular status of all restrained extremities constantly monitored.

Patient Restraint

Never restrain the patient in a prone position with neck function restricted or pressure on the chest or neck, as these positions are dangerous and can lead to asphyxiation. If the patient is already restrained in such a position when you arrive, you are responsible for safely placing the patient into an acceptable position/restraint as quickly as possible.

In an intubated patient, a properly placed esophageal temperature probe provides continuous, real-time core temperature measurements and is ideal for critically ill patients. A urine bladder thermistor catheter can also provide continuous monitoring of both temperature and urine output. Of note, ensuring the accuracy of monitoring requires the patient to have at least minimal urine output; in addition, measurements have been reported to lag behind changes in core temperature by as much as 20 minutes. If these temperature measurement devices are unavailable or contraindicated, a rectal temperature provides the next best method for intermittent or continuous core temperature monitoring, as indicated by clinical concern for worsening hyperthermia. The least invasive method is to use a temporal artery infrared thermometer; although it does not provide a core body temperature measurement, its findings can supplement the clinical exam and assist with medical management decisions. The goal of active cooling is to achieve a core temperature of less than 39°C (102.2°F).

End-tidal capnography (the graphical measurement of ETCO_2) monitoring is of great benefit in patients with excited delirium. First, it provides useful real-time monitoring of the patient’s respiratory status. Any change in the respiratory rate, including apnea, can be immediately recognized well before the pulse oximetry value changes. Second, the quantitative ETCO_2 value has been shown to be helpful in screening for metabolic acidosis. The body's natural response to metabolic acidosis is to induce a compensatory respiratory alkalosis by hyperventilation, which will drive down the measured $ETCO_2$. Patients with significant metabolic acidosis often display a characteristic respiratory pattern consisting of large tidal volumes and rapid respiratory rate to generate a large minute ventilation (ie, Kussmaul respiration). An $ETCO_2$ threshold of greater than 36 mm Hg in most patients indicates that a significant metabolic acidosis is unlikely.

The relevance of this measured $ETCO_2$ value depends on the presence of spontaneous respirations and inherent functional acid–base regulatory mechanisms. With patients who are paralyzed or highly sedated and intubated, the $ETCO_2$ level more closely represents the ventilation rate and tidal volume than the underlying acid–base status. In these situations, it is critically important to understand that the ventilation rate, or more accurately the total minute ventilation volume (tidal volume × respiratory rate), should not be titrated to a normal $ETCO_2$ level (35 to 45 mm Hg), as would typically be the case. Instead, the total minute ventilation volume should be adjusted to a respiratory alkalosis (less than 35 mm Hg) to compensate for the underlying metabolic acidosis, because patients cannot spontaneously adjust their own respiratory rate to compensate for this imbalance. In patients with severe metabolic acidosis, $ETCO_2$ targets as low as 10 to 15 mm Hg may be necessary. Obtaining an $ETCO_2$ value for a spontaneously breathing patient with a patent airway prior to intubation, if possible, allows the CCTP to titrate the ventilator settings to obtain a postintubation minute ventilation that mirrors the preintubation $ETCO_2$ value.

When performing RSI, administering 1 to 2 mEq/kg of sodium bicarbonate 3 to 5 minutes before intubation may help raise the pH and prevent acute decompensation during the apneic period that occurs during intubation. Minimizing the use of postintubation sedation medications that depress the respiratory drive (eg, benzodiazepines and propofol) and avoiding the use of long-acting paralytics (eg, vecuronium and rocuronium) may allow an intubated patient to continue respiratory compensation via spontaneous breathing. Ketamine has also been used successfully to achieve postintubation sedation without inhibiting spontaneous breathing. Without respiratory compensation, the patient could become severely acidemic, leading to dangerous arrhythmias and cardiovascular collapse. If the preintubation $ETCO_2$ value is known, then it is an appropriate initial target after mechanical ventilation is initiated, so as to match the patient's inherent compensatory drive.

Ongoing ventilator management is best accomplished with the aid of arterial blood gas analysis, although this test is not routinely available during most interfacility transports. Maximal compensation may take 12 to 24 hours to achieve its full effects, but the maximally compensated arterial carbon dioxide ($Paco_2$) level can be calculated using Winter's formula (expected $Paco_2 = 1.5 \times (\text{actual } [HCO_3]) + 8$ mm Hg), which gives a reasonable target $ETCO_2$ for initial ventilator settings. Generally, if the cardiac output remains sufficient, then the $ETCO_2$ value runs approximately 2 to 4 mm Hg lower than the $Paco_2$ value, and this correlation can be verified by documenting the measured $ETCO_2$ at the time the blood gas is drawn for analysis. Adequate respiratory compensation for the underlying metabolic acidosis is provided by titrating ventilator settings (respiratory rate and tidal volume) to achieve this goal $ETCO_2$ level.

Children With Special Health Care Needs

Children with special health care needs (CSHCN) are defined by the US Department of Health and Human Services as "those who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally." With advancements in medicine, more children have become able to survive with chronic conditions, and they can often be cared for in a home setting. According to the National Survey of Children's Health, CSHCN account for approximately 18.5% of the pediatric population. Thanks to the many advances in medicine and technology, many children who would otherwise spend time in the hospital and intensive care unit (ICU) can be sent home with nursing coverage and specialized equipment.

Within this population, children with medical complexity (CMC) are at particular risk of receiving lower-quality health care. CMC have chronic medical disease and significant functional limitations. The conditions affecting these children may be congenital, such as hypoplastic left heart syndrome, or acquired, such as brain injury. CMC may be dependent on medical technology. Technologies used may include respiratory supports or monitoring equipment (eg, tracheostomy, ventilator, apnea monitor), enteral feeding devices (eg, nasogastric, gastrostomy, or jejunostomy tube), indwelling IV access (eg, peripherally inserted central catheter, implanted port), colostomies, ventricular shunts (eg, ventriculoperitoneal, external ventricular drain), and baclofen pumps.

This section discusses the basic pathophysiology of common anomalies, the implications for the CCTP, and care and use of the technologies associated with these anomalies.

Congenital Heart Defects

A congenital heart defect (CHD) affects nearly 1% of live births each year in the United States, with approximately one in four of these CHDs being a critical condition that requires surgery or other procedures in the first year of life. The clinical consequences of a CHD are heart failure and hypoxemia. Commonly, symptomatic hypoxia (pallor, respiratory distress, altered mental status) or inadequate end-organ perfusion from heart failure prompts the need for medical care.

Classification of CHDs

CHDs historically were classified as cyanotic or acyanotic **FIGURE 25-16**. The newer classifications are based on hemodynamic characteristics and include four categories: (1) increased pulmonary blood flow; (2) decreased pulmonary blood flow; (3) mixed blood flow; and (4) obstructive blood flow out of the heart **TABLE 25-4**.

Description

TABLE 25-4 Classification of Congenital Heart Defects

- Increased pulmonary blood flow (acyanotic)
  - Atrial septal defect
  - Ventricular septal defect
  - Patent ductus arteriosus
  - Atrioventricular canal
  - Decreased pulmonary blood flow (cyanotic)
    - Tetralogy of Fallot
    - Tricuspid atresia
- Obstruction of blood flow from the heart (acyanotic)
  - Coarctation of the aorta
  - Aortic stenosis
  - Pulmonic stenosis
- Mixed blood flow (cyanotic)
  - Transposition of the great vessels
  - Total anomalous pulmonary venous return
  - Truncus arteriosus
  - Hypoplastic left heart syndrome

© Jones & Bartlett Learning.

Acyanotic defects are usually caused by increased pulmonary blood flow and obstructive blood flow out of the heart. The increased pulmonary blood flow classification is based on defects that cause a left-to-right shunt, resulting in oxygenated blood repeatedly going through the pulmonary system. Depending on the size of the defect and the volume of blood that flows between them, acyanotic defects can cause heart failure due to volume overload. Although types of CHD are individually described, some patients may have multiple types or more unique defects.

- **Atrial septal defect (ASD)** is an opening in the septal wall of the heart between the left and right atria that allows blood flow from the left atrium to the right atrium **FIGURE 25-17A**.

- In **ventricular septal defect (VSD)**, blood flows from the left ventricle to the right ventricle through a hole in the septal wall **FIGURE 25-17B**.
- **Atrioventricular canal defect** consists of both VSD and ASD as well as a defect affecting the mitral and tricuspid valves, in which the valves are shared **FIGURE 25-17C**.
- A **patent ductus arteriosus (PDA)** is an extra blood vessel that allows blood to flow from the aorta to the pulmonary artery **FIGURE 25-17D**. In the neonate, the PDA usually closes completely within the first 12 to 24 hours of extrauterine life as the result of increased blood oxygenation and pressure, and decreased levels of endogenous prostaglandins. In some types of CHD, such as hypoplastic left heart syndrome, a PDA may act as the only route for blood to reach systemic circulation and the vessel is kept open through medications.

Acyanotic CHDs associated with obstructive blood flow are coarctation of the aorta, aortic stenosis, and pulmonic stenosis:

- **Coarctation of the aorta** is the narrowing or constriction of part of the aorta or aortic arch **FIGURE 25-18A**. Although it is considered an acyanotic defect, one sign of this disease in the neonate may be cyanosis of the lower extremities despite baseline skin color in the upper extremities, a condition known as differential cyanosis. These neonates may present with circulatory collapse. Femoral pulses may be absent but can also be present due to collaterals, so make sure to palpate for distal extremity pulses.

- **Aortic stenosis** is narrowing of the aortic valve **FIGURE 25-18B** and can be described as valvular, supravalvular, or subvalvular.
  - *Valvular stenosis*, the most common form of aortic stenosis, can be caused by development of a bicuspid valve instead of the normal tricuspid valve.
  - *Supravalvular stenosis*, the least common form of aortic stenosis, is the result of narrowing of the aorta above the aortic valve and coronary arteries.
  - *Subvalvular stenosis* can be the result of isolated lesions or other congenital heart anomalies.
- **Pulmonic stenosis**, also known as pulmonary stenosis, is obstruction of blood flow from the right ventricle to the pulmonary artery **FIGURE 25-18C**.

© Jones & Bartlett Learning.

Cyanotic defects consist of decreased pulmonary blood flow and mixed blood flow. Decreased pulmonary blood flow includes the following two defects:

- **Tetralogy of Fallot (TOF)** is the combination of four anomalies: VSD, pulmonary stenosis, overriding aorta, and right ventricular hypertrophy **FIGURE 25-19A**. Because it is one of the most common forms of CHD, CCTPs must be aware of the interventions needed to treat these patients. Infants with TOF may have hypercyanotic spells (called tet spells) that are characterized by increased cyanosis, irritability, tachycardia, and tachypnea.
- **Tricuspid atresia** is the result of an absent or defective tricuspid heart valve, which causes blood flow from the right atrium to the right ventricle to be blocked **FIGURE 25-19B**.

© Jones & Bartlett Learning.

Description Description

The mixed blood flow classification consists of transposition of the great vessels and hypoplastic left heart syndrome.

- **Transposition of the great vessels** is a defect in which the aorta receives blood from the right ventricle while the pulmonary artery leaves the left ventricle **FIGURE 25-20A**. Often these patients also have a patent foramen ovale and VSD.

- **Hypoplastic left heart syndrome** is caused by an abnormally small left ventricle **FIGURE 25-20B**. It is often associated with aortic and mitral valve stenosis or atresia. Obstruction to the left side of the heart results in heart failure, whereas obstruction to the right side of the heart results in hypoxemia and cyanosis.

Description Description

Heart failure is defined as a set of clinical signs and symptoms indicative of myocardial dysfunction and cardiac output that is inadequate to meet the metabolic demands of the body. Common signs and symptoms of heart failure can be divided into four classifications, as shown in **TABLE 25-5**. In infants, some of the common signs of heart failure are often apparent during their feedings: tachycardia, nasal flaring, irritability, diaphoresis, sweating with feeds, and easily becoming fatigued. However, tachypnea may also be the only sign of heart failure in children.

TABLE 25-5 Signs and Symptoms of Heart Failure in Children

Adrenergic Response

- Tachycardia
- Tachypnea
- Cool skin
- Diaphoresis
- Oliguria

Systemic Venous Congestion

- Hepatomegaly
- Periorbital edema
- Pulmonary effusion, ascites (rare)

Pulmonary Venous Congestion

- Tachypnea
- Retractions
- Nasal flaring
- Pulmonary edema

Cardiorespiratory Distress

- Irritability
- Altered mental status
- Fatigue
- Poor feeding
- Sweating with feeds
- Failure to thrive
- Gray skin coloration

Assessment

A diagnostic tool that CCTPs can use to determine if a critical CHD is present is pulse oximetry. Placing one pulse oximetry probe on the child's right wrist and another probe on a foot can allow the CCTP to identify any difference in preductal and postductal oxygen saturation (Spo_2) levels, which would be indicative of right-to-left shunting as well as coarctation of the aorta.

Another simple monitoring tool that can be used in an infant or child with CHD is measurement of BP in the upper and lower extremities. If the systolic BP reading in the right upper extremity is substantially higher than the reading in the lower extremity, then an obvious obstruction of blood flow is present, such as coarctation of the aorta. Another finding in patients with coarctation of the aorta may be diminished or weak pulses in the lower extremities compared with the upper extremities.

Many patients with CHD may require cardiac surgeries, which are often staged into multiple procedures over years. Some degree of hypoxemia may be expected in these patients, such as those with hypoplastic left heart syndrome, before definitive operative repair or transplant. Family or other caregivers who are present may act as a source of information on their baseline oxygen level and clinical status.

Treatment

It is important for the CCTP to have a basic understanding of CHDs and to obtain accurate histories from the parents and/or caregivers of these patients. Some of these defects, such as coarctation of the aorta and hypoplastic left heart syndrome, require patency of the ductus arteriosus for survival. Administration of oxygen must be approached cautiously in these infants, as it will accelerate PDA closure, which could be fatal. Some of these patients have normal Spo_2 levels in the range of 70% to 90%; if the Spo_2 level goes any higher, it may increase their risk of PDA closure, which may then lead to heart failure.

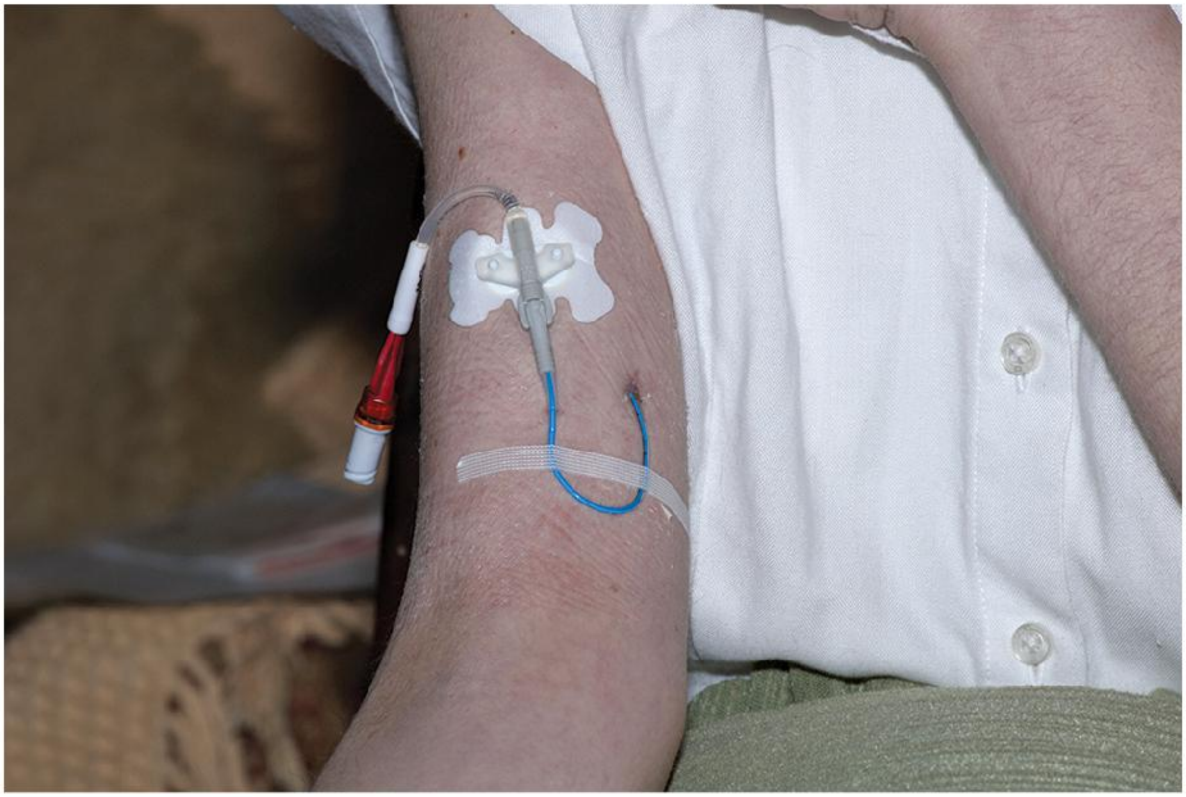
Ductal-dependent conditions may require administration of prostaglandin, which will help maintain the patency of the ductus arteriosus. Conversely, indomethacin is a medication that is administered to facilitate closure of the PDA.

Intravenous fluid administration must be used cautiously in pediatric patients with CHD. Although most children can handle an IV bolus of 20 mL/kg, these vulnerable patients must be closely monitored and given only 10 mL/kg to prevent fluid overload or pulmonary edema.

Infants with TOF often present with irritability, decreased feeding, and hypercyanotic spells (tet spells), which are a medical emergency. Tet spells present with tachypnea and agitation, and can result in loss of consciousness, altered mental status, and death. Initial interventions for tet spells include placing the patient in the knee-to-chest position or having an older child squat. If these measures do not work, administer IV morphine and IV fluid bolus (5–10 mL/kg). If these interventions do not work, you can give a phenylephrine continuous infusion or propranolol, but use caution with the latter medication, as it may cause hypotension.

Hematology-Oncology Pediatric Patients

When caring for the hematology–oncology population in pediatrics, it is important to remember that these patients have weakened immune systems. Fever, even the slightest low-grade fever, is an emergency in this population. This section discusses the most common hematologic–oncologic pediatric conditions seen by CCTPs: neutropenia, sickle cell anemia, and hemophilia. These children often have specific devices in place, such as peripherally inserted central catheters **FIGURE 25-21A**, central venous access devices (CVADs) **FIGURE 25-21B**, or central venous catheters **FIGURE 25-21C**. For the most part, CCTPs must be specially trained by different facilities to access these devices, owing to the high risk of infection. CCTPs should follow their agency's policies and procedures for using these devices.



A

Pediatric patients with hematologic–oncologic conditions are a vulnerable population. As critical care providers, CCTPs must protect these children from opportunities for infection. Because such patients are immunocompromised and often have neutropenia, strict isolation techniques are required in their care. **Neutropenia** is a decrease in the number of neutrophils in the body; neutrophils are essential in the body's immune response system. Strict isolation techniques to reduce the chance of infection include strict hand hygiene, limiting invasive procedures, and having patients wear a mask when out of their room or going for a procedure. Parents and/or caregivers are taught to call the oncologist or hematologist and bring their child into the ED when the child begins to have even the slightest fever at home. These children are at increased risk for sepsis and shock.

Sickle Cell Anemia

Sickle cell anemia affects 1 in 365 black or African American infants born in the United States and approximately 100,000 Americans overall. Children with sickle cell anemia have inherited two sets of recessive genes that produce an abnormal hemoglobin protein, known as Hgb S. When the child's oxygen level decreases, it affects the hemoglobin (Hgb); in turn, the red blood cell (RBC) becomes deformed. Specifically, instead of being circular in shape, the RBC assumes more of a sickle shape **FIGURE 25-22**. The RBCs also become "sticky," so that they occlude vessels, clot, and cause great pain in patients. Children with sickle cell anemia often present with chest pain, extremity pain, and difficulty breathing. In the worst-case scenario, these children may have a cerebral vascular accident.

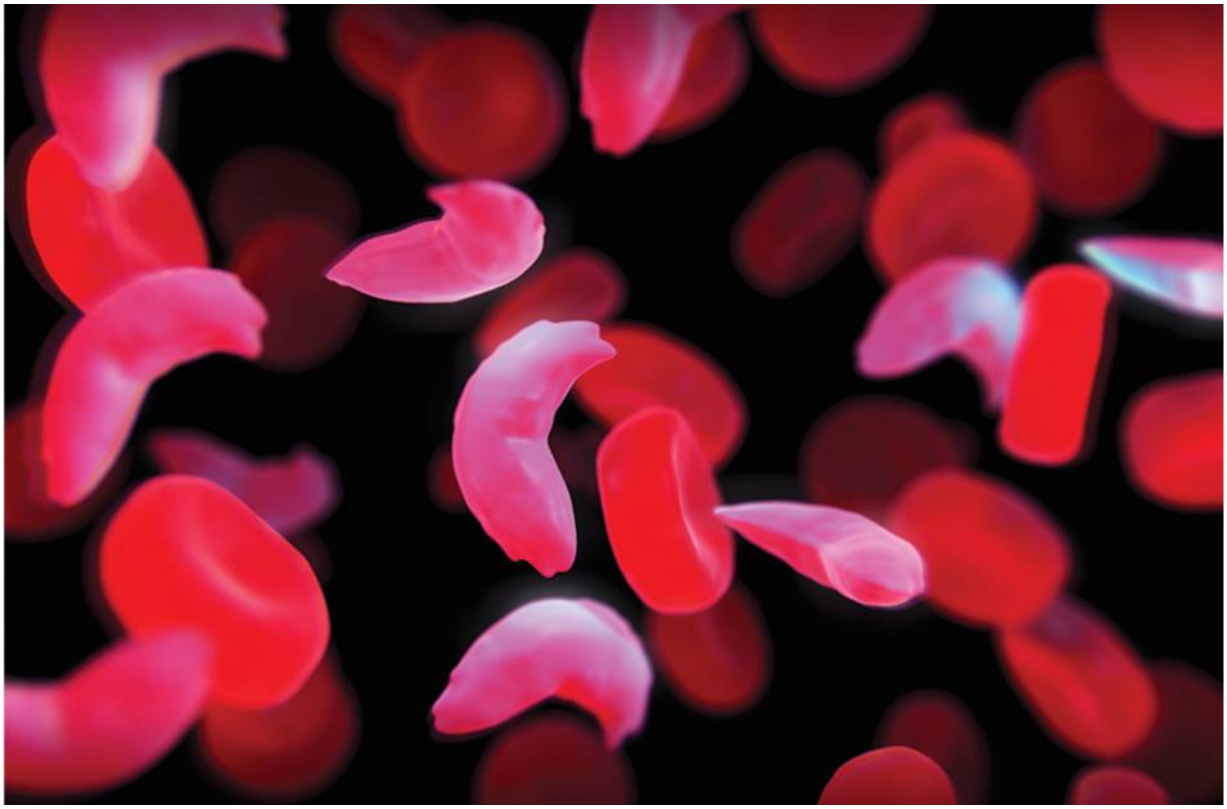

FIGURE 25-22 Red blood cells with a sickle shape.

© Science Picture Co/Collection Mix: Subjects/Getty Images.

When children present in sickle cell crisis, aggressive treatment is necessary. Sickle cell crisis or vaso-occlusive crisis is associated with clinical signs of anemia, pallor, weakness, fatigue, and severe pain. These patients require oxygenation, an IV fluid bolus of isotonic crystalloids, or, if tolerated, oral rehydration. In severe cases, children may require blood transfusions. Pain management is extremely important, because these patients will be in severe pain. A life-threatening emergency in patients with sickle cell anemia is acute chest syndrome, which can be due to pneumonia or infarction. This condition typically presents as chest pain, hypoxia, tachypnea, fever, and crackles. As noted previously, these patients are at high risk for stroke, so providers should assess for classic stroke signs such as unilateral weakness, altered speech, and blown pupils. The CCTP must follow local policies, procedures, and protocols when managing these patients.

Hemophilia

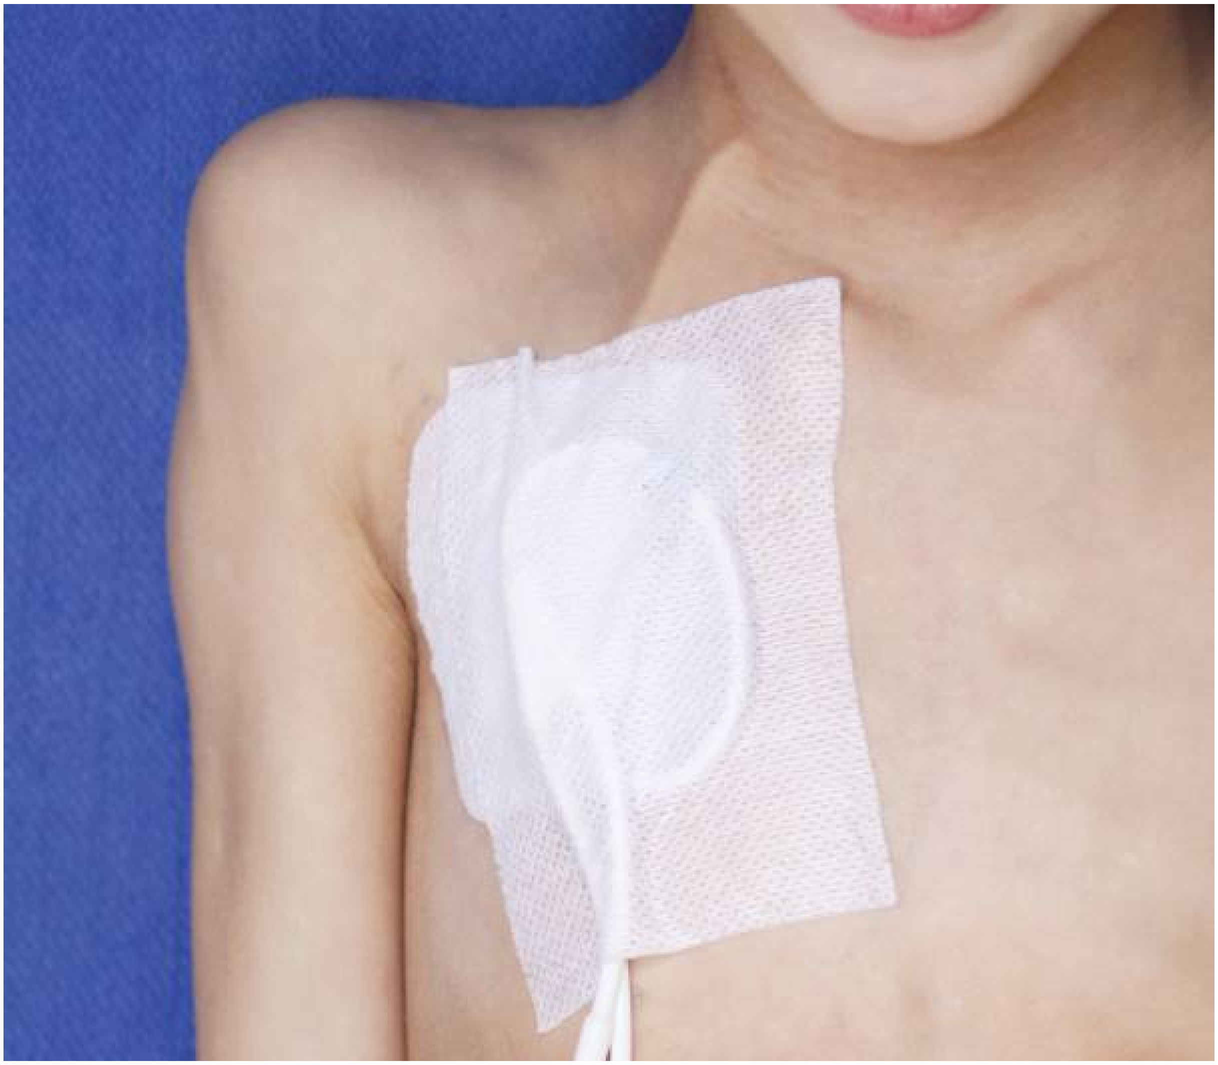
Patients with **hemophilia** have a recessive gene trait that causes excessive bleeding. This disorder is caused by factor VIII or factor IX deficiency, which prevents blood from clotting properly. In the United States, factor VIII deficiency (also called hemophilia A or classic hemophilia) is the most common form of hemophilia. It affects 12 in every 100,000 males and is four times as prevalent as factor IX deficiency (also called hemophilia B or Christmas disease).

Children with hemophilia are at increased risk of bleeding from even the slightest injury. For example, something as simple as falling from a standing position and bumping the head on the floor or table can cause serious bleeding issues. Serious, life-threatening injuries for these children are injuries that occur to the head, neck, chest, and abdomen.

When faced with an injury to a child with hemophilia, first and foremost the CCTP must treat any obvious bleeding. These children require immediate IV administration of factor VIII for hemophilia A, or factor IX for hemophilia B.

Pediatric Patients With Venous Access Devices

Venous access devices include tunneled catheters, implanted ports, and peripherally inserted central catheters. Tunneled catheters can have single, double, or triple lumens and are inserted in the right or left subclavian vein. Several different types of long-term CVADs are available, such as Hickman, Broviac, and Groshong catheters **FIGURE 25-23**. Implanted ports require specific Huber needle infusion sets to access the device; the various types of implanted ports are known as Mediport, Port-A-Cath, and Infusaport devices.



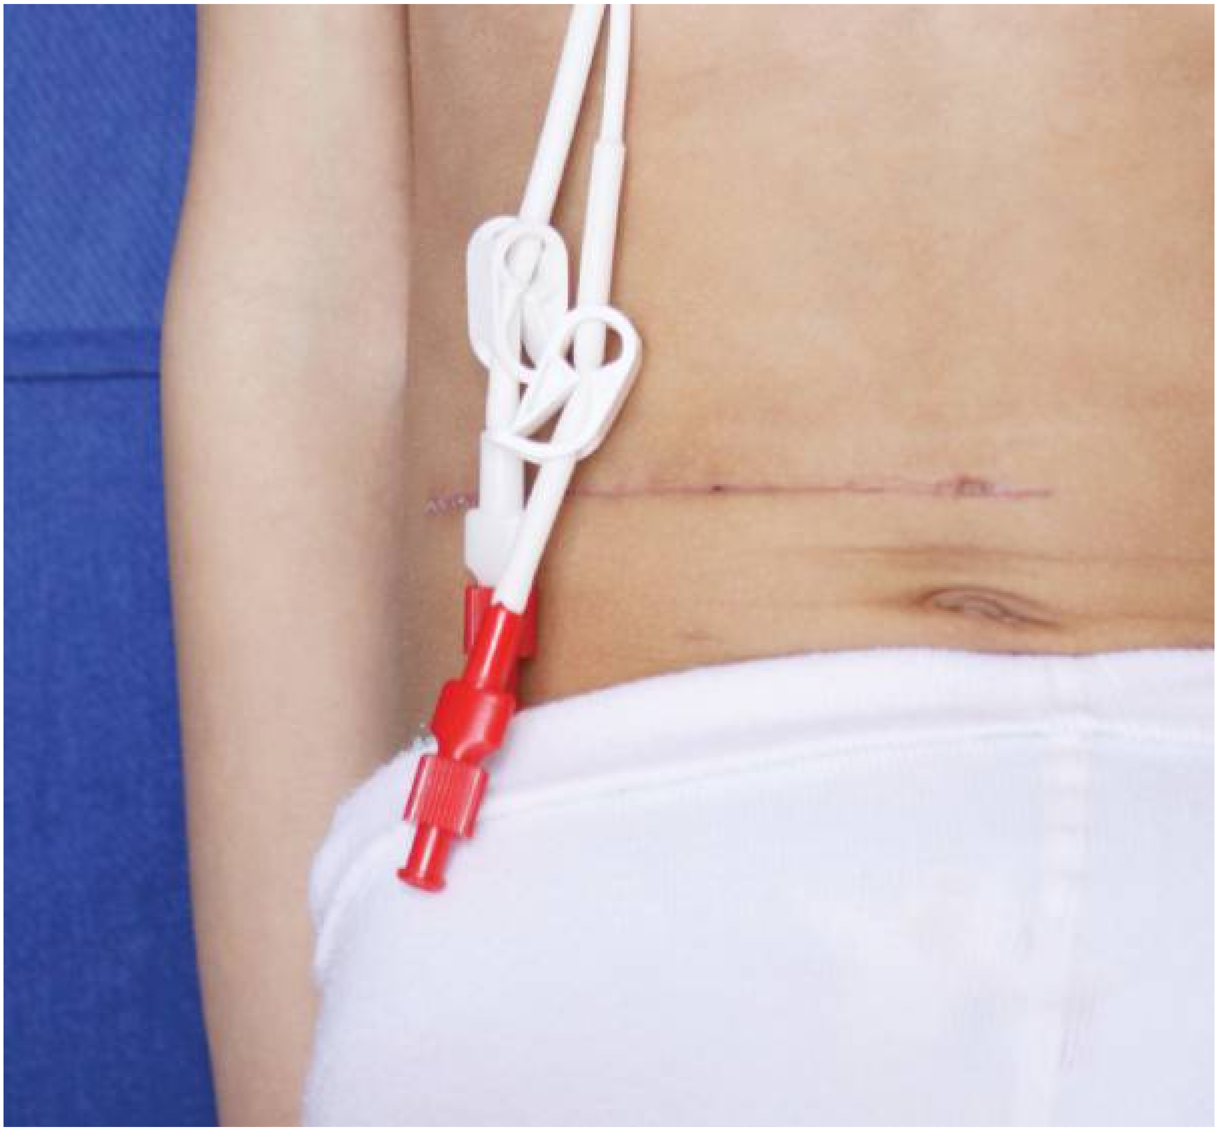


FIGURE 25-23 Long-term central venous access devices.

© frantab/Shutterstock.

Depending on the specific catheter, the smallest syringe that may be used with these devices might be a 10-mL syringe. Using anything smaller than a 10-mL syringe to aspirate fluid from the device may damage the catheter. It may also cause the catheter to collapse while aspirating the blood.

Prior to children being discharged to home with a venous access device, parents are given training and hands-on experience in accessing the device, performing dressing changes, flushing the device, and administering medication through the device. Home health infusion nurses may visit the family and patient once per week to deliver medications and supplies, and to inspect the sites. Changing the dressings for all devices and accessing the implanted ports require sterile technique. These techniques are specific, and are based on the manufacturer’s guidelines. Depending on their agency’s policies or protocols, CCTPs may or may not be able to use these devices for blood draws, medication administration, or IV fluid infusions. Like all indwelling devices, long-term CVADs and ports may act as a source for infection as well.

Pediatric Patients With Respiratory Disorders

Two commonly encountered respiratory disorders that may require or be the result of long-term ventilation, endotracheal tube placement, or tracheostomy placement in pediatric patients are bronchopulmonary dysplasia and tracheomalacia.

Bronchopulmonary dysplasia, or chronic lung disease, usually occurs in premature infants who weigh less than 3 pounds (1,500 g) at birth, approximately 25% of whom have respiratory distress syndrome. These neonates have long-term fibrosis and scarring sustained from oxygen toxicity, often requiring mechanical ventilation. These children may require tracheostomies, mechanical ventilation, and $ETCO_2$ monitoring. Acute bronchopulmonary dysplasia exacerbations are often triggered by viral illnesses, weather changes, or crying, and can present with respiratory distress, decreased air entry, apnea, desaturations, coarse breath sounds, wheezing, and crackles.

Tracheomalacia is a weakening or softening of the tracheal cartilage/rings that causes the trachea to become floppy and collapse during expiration. It can be due to compression from surrounding structures or intrinsic defects of the trachea, or it can occur in patients who have been on prolonged positive-pressure ventilation. Affected children are noisy breathers and often sound as if they have a continuous stridor. The stridor will worsen with crying, irritability, and lying supine. It is important to obtain an accurate history to ascertain if the child with stridor has a history of tracheomalacia because the administration of bronchodilators, such as albuterol, can worsen the symptoms by causing the airway to become more floppy and even cause the airway to collapse. Positioning of these patients plays an important role in alleviating the symptoms. Placing infants and children with tracheomalacia in a prone position allows gravity to assist in opening the airway; the supine position would be dangerous due to narrowing of the weakened trachea or even airway collapse.

Tracheostomy tubes are used in pediatric patients who require long-term mechanical ventilation, are unable to manage their secretions, or have physical or anatomic barriers to their native airway (stenosis, tracheomalacia, radiation scarring, laryngectomy). These devices are made of materials that soften when exposed to body temperature, which allows the tracheostomy tube to conform with the trachea. The tracheostomy tube may be a complete set with an obturator, or it may consist of an obturator, inner cannula, and outer cannula **FIGURE 25-24**. The obturator is used to guide the tracheostomy tube into the stoma, much like the stylet is used for an endotracheal tube. The tube is then secured with the cuff inflated, and tracheal ties are placed around the patient’s neck to secure the tube.

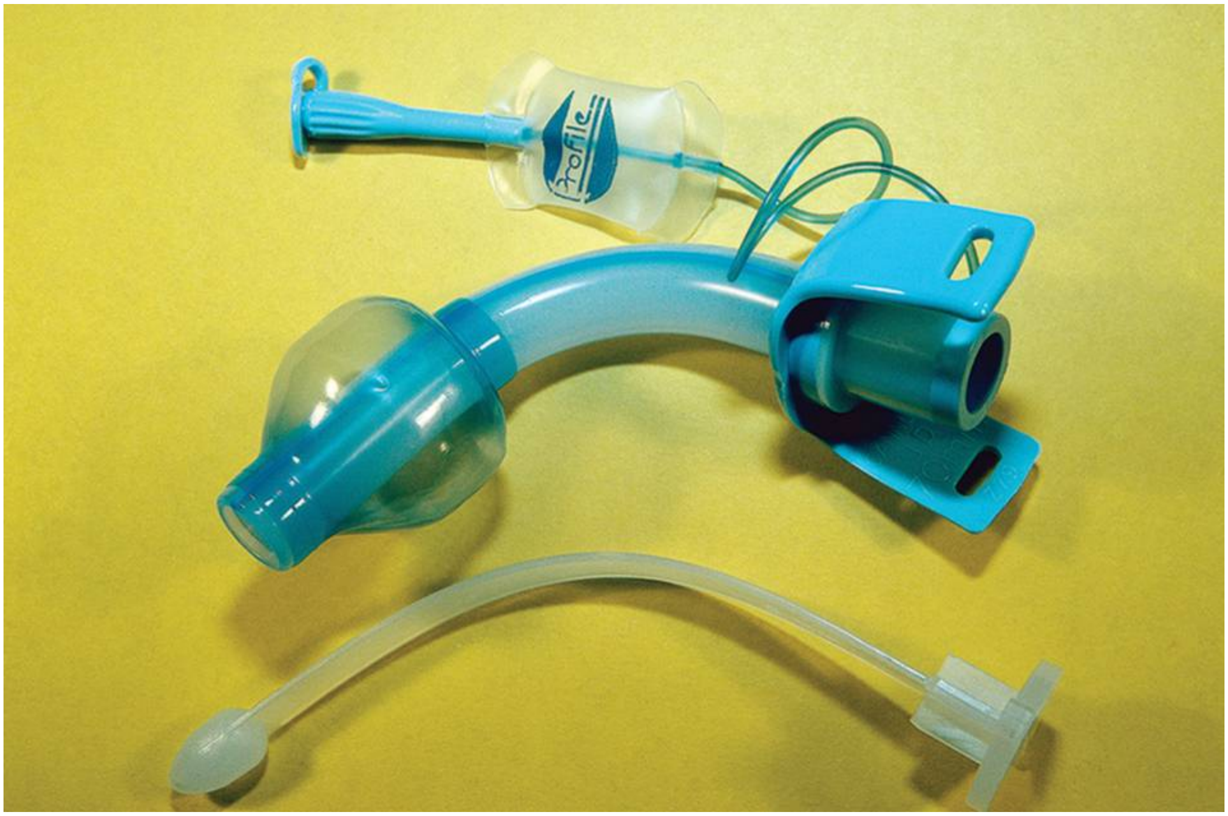

FIGURE 25-24 Tracheostomy tubes.

© Mediscan/Alamy Stock Photo.

During ventilation, the cuff remains inflated to allow for a closed circuit. However, many patients with tracheostomies do not require around-the-clock ventilation. In patients who do not require pressure support, the tracheostomy may remain open with a tracheostomy collar providing moisture, or a heat moisture exchanger may allow for humidity to prevent overdrying of secretions. In other patients, a one-way valve (ie, a speaking valve or Passy Muir valve) may be in place. These valves allow the patient to inhale through the tracheostomy, but the one-way design allows exhalation through the native airway (and through the vocal cords, allowing for speech). Because of the one-way function of these valves, they can be used only with the cuff deflated. If the cuff is inflated, there would be no way to exhale the air, creating a life-threatening situation. The pilot balloon allows providers to know if the cuff is inflated or deflated. If the pilot balloon is full, the cuff is inflated; if it is not full, the cuff is deflated.

Because damage to the trachea can occur easily, it is important to ensure that the cuff is not overinflated. It is also important to remember that because the tracheostomy tube bypasses the normal “warmth and filtration” system that the nasal passages provide, the CCTP must administer only warmed, humidified oxygen via an oxygen warming device or a humidivent attachment.

Children who require tracheostomy tubes have weakened airways, so they may not be able to fully cough up secretions. Some children are dependent on intermittent suctioning of these secretions. Mucus plugging can obstruct the tube, causing respiratory arrest; thus, suctioning is an important part of the assessment. Alternatively, in some patients, suctioning may cause a vagal response, inducing bradycardia, so CCTPs must closely monitor the clinical response to suctioning interventions.

When caring for a child with a tracheostomy tube, the CCTP should ensure that an obturator, an extra tracheostomy tube of the same size, and a tracheostomy tube of a size smaller are readily available in case the tube is accidentally pulled out of place. Common complications encountered with tracheostomy tubes are the same as those linked to endotracheal tubes.

When changing the tracheostomy tube, it is important to place a towel roll under the patient’s shoulders **FIGURE 25-25**. This step puts the child into the “sniffing” position and allows for easier insertion of the tracheostomy tube.

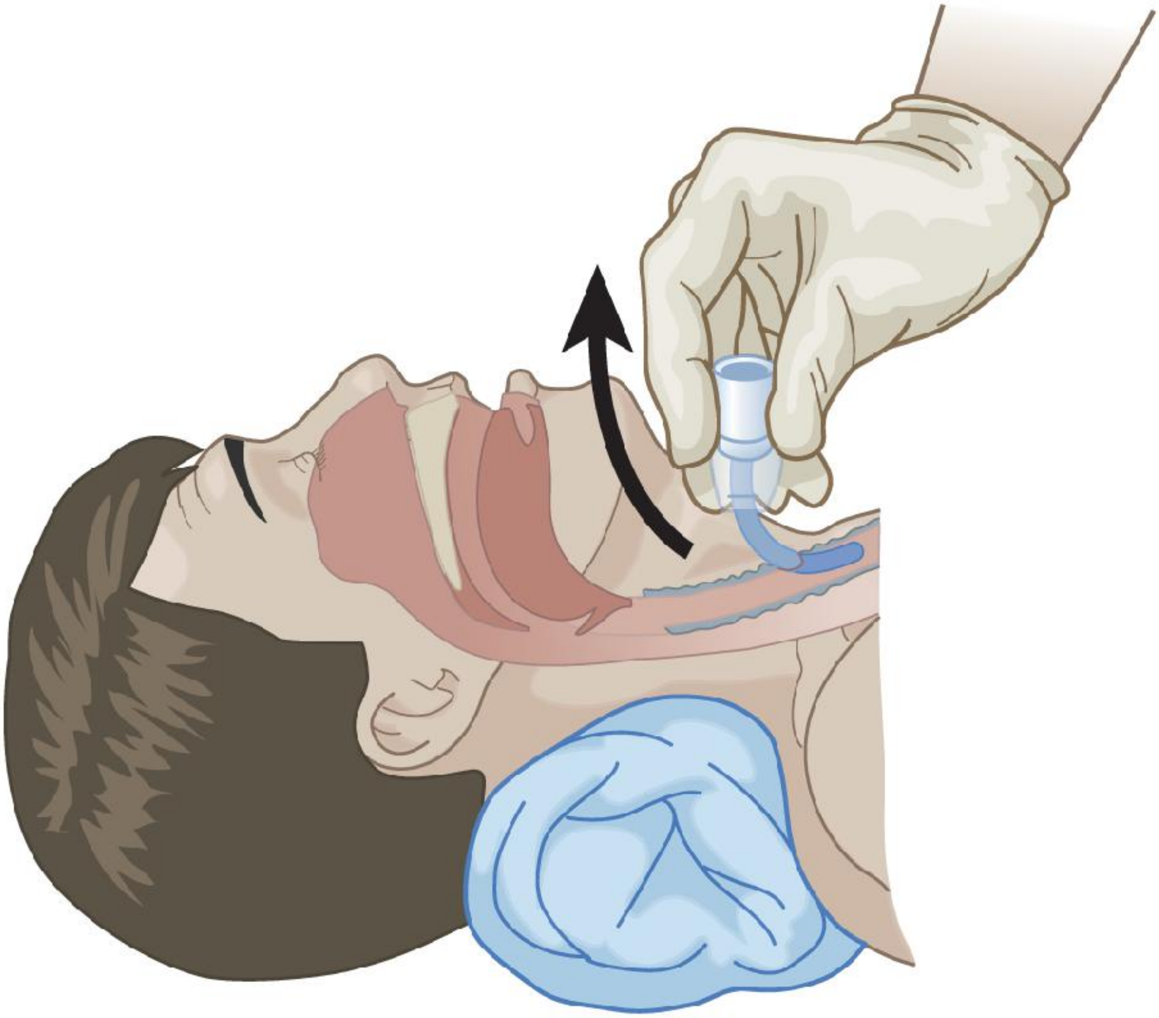

FIGURE 25-25 When changing the tracheostomy tube, place a towel roll under the patient's shoulders to ensure the patient is in the sniffing position.

Children with respiratory disorders who are being cared for at home often have a "go-bag" with them. The go-bag will contain extra tracheostomy tubes of the same size and one size smaller, suction catheters, portable suction, a bag-mask device (Ambu bag), oxygen administration sets, nebulizers, and other emergency medications that these children may require, along with a binder containing a list of emergency contacts (physician, hospital numbers, home health care agency), medication administration record, past medical history, and allergy information. When transporting the child from home, providers should ask the family to bring this bag with them.

Pediatric Patients With Neurologic Disorders

Hydrocephalus is the result of accumulation of cerebrospinal fluid (CSF) due to an imbalance between production and reabsorption of CSF. Hydrocephalus can be differentiated into two types:

- *Congenital hydrocephalus* can be the result of a myelomeningocele, cytomegalovirus infection, or aqueduct stenosis.
- *Acquired hydrocephalus* can be the result of intraventricular hemorrhage, tumor, meningitis, or head injury.

Essentially, in hydrocephalus, CSF is unable to reach the subarachnoid space due to a blockage or injury and builds up in the ventricles **FIGURE 25-26**. As a result, these children will present with abnormally large heads, poor feeding, restlessness, bulging fontanelles, shrill or shrieking cry, upward gaze paralysis (the “sunset sign”), and inconsolability; they may also have dilated scalp veins.

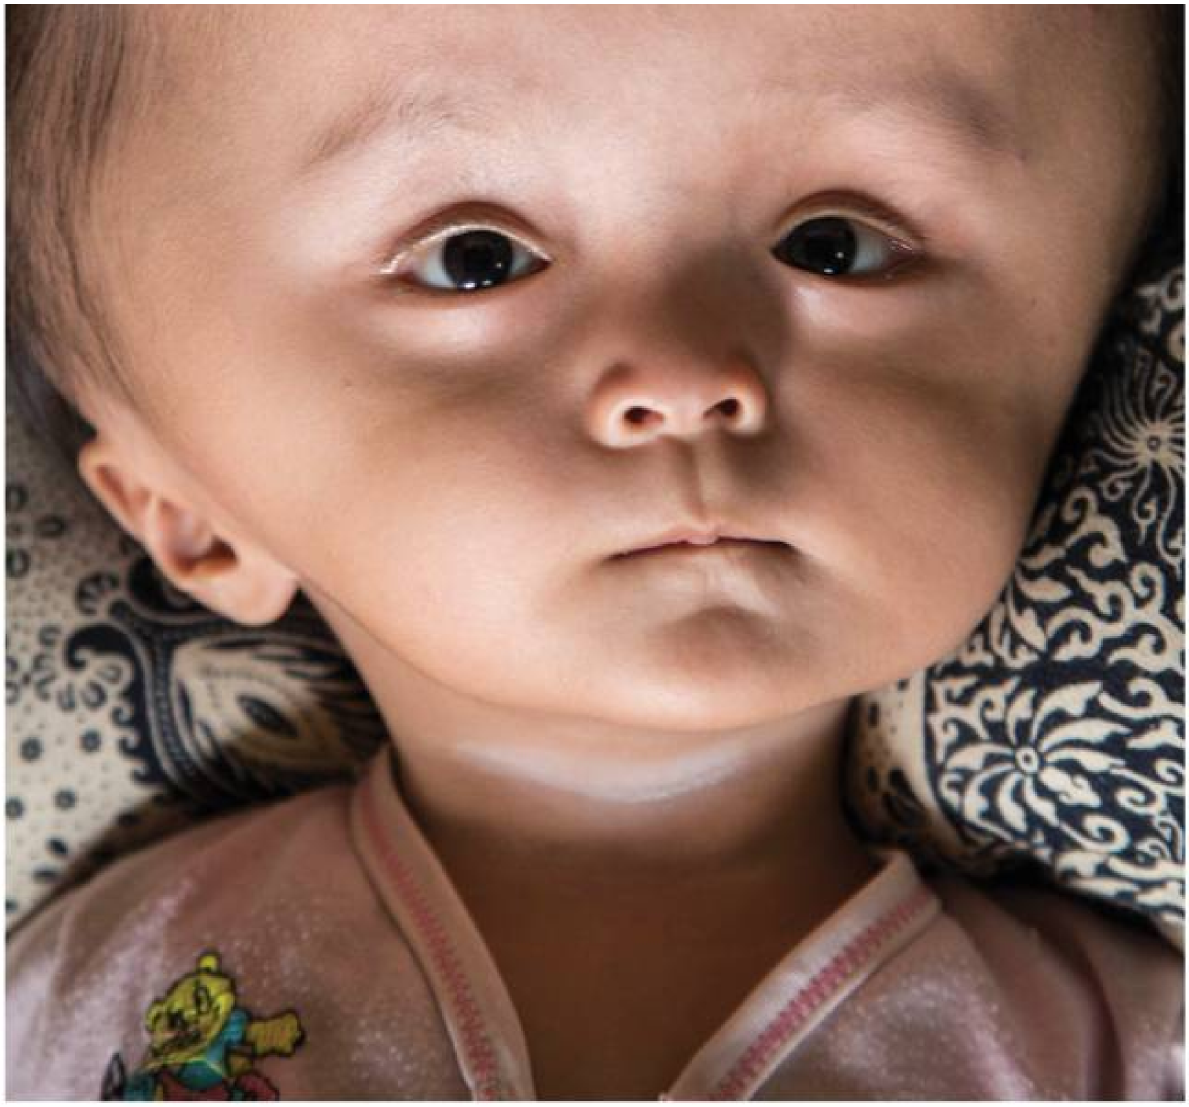

FIGURE 25-26 In hydrocephalus, the ventricles become enlarged due to buildup of cerebrospinal fluid.

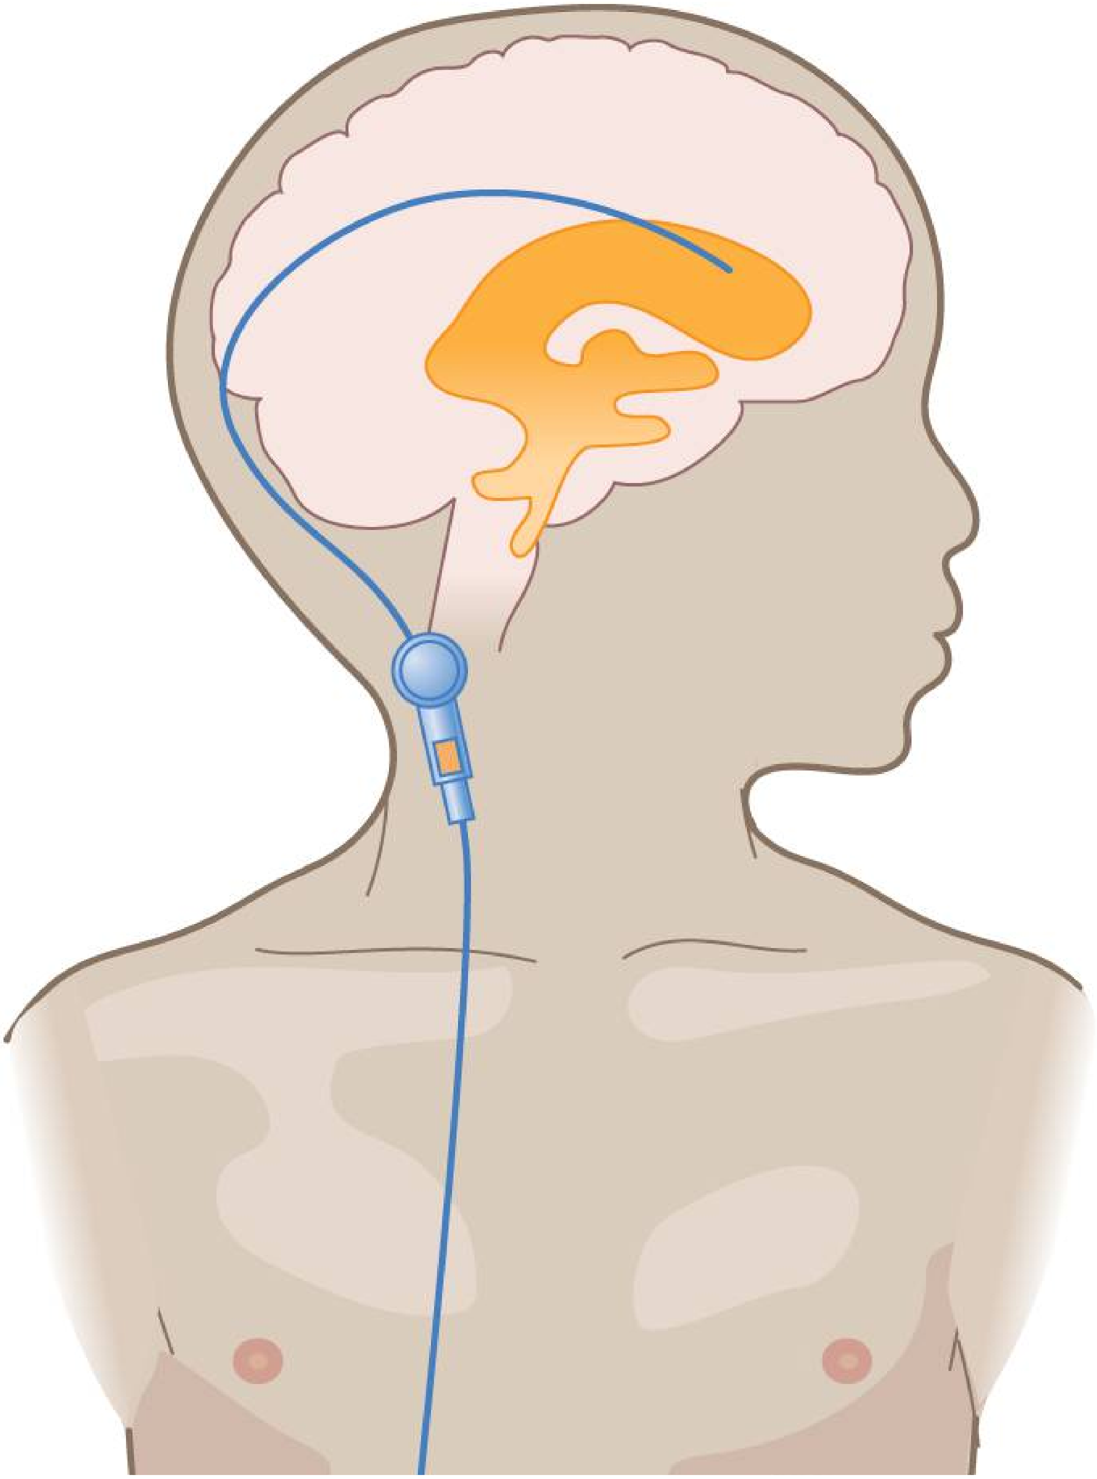
© Donal Husni/NurPhoto/Getty Images.

Children with symptomatic hydrocephalus require surgical intervention and often have a ventriculoperitoneal (VP) or ventriculoatrial (VA) shunt placed, or undergo endoscopic third ventriculostomy. A VP shunt consists of a ventricular catheter that is inserted into a lateral ventricle; the distal end of the catheter then runs down to the peritoneal cavity via a flush pump and unidirectional-flow valve **FIGURE 25-27**. Older children who have finished going through so-called growth spurts or somatic growth may have a VA shunt. A VA shunt consists of a catheter going from a lateral ventricle into the right atrium. VA shunts may also be placed in children with abdominal issues that contraindicate a VP shunt.



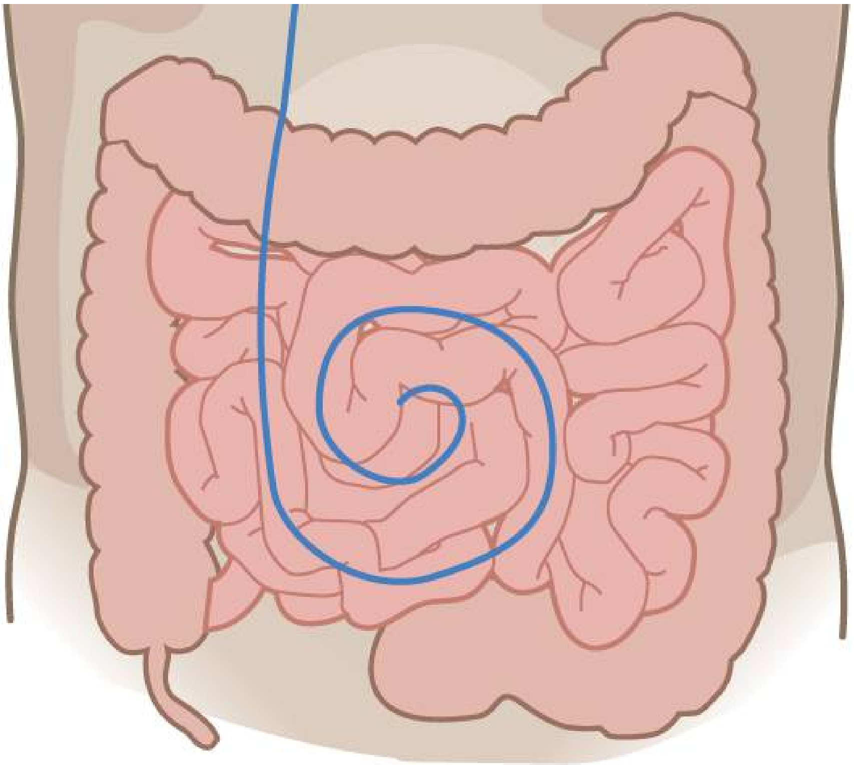


FIGURE 25-27 A ventriculoperitoneal shunt.

© Jones & Bartlett Learning.

The CCTP will often encounter these children when they have a shunt malfunction or infection. VP shunts are susceptible to malfunction or may need revisions during growth spurts. Indeed, 40% of VP shunts usually need to be revised after 1 year, and 50% require revision at 2 years. Infection rates are especially high within the first 6 months of placement. Signs and symptoms of VP shunt malfunction or infection include fever, vomiting, altered mental status, dizziness, restlessness, irritability, headache, neck pain, and seizures.

Children with malfunctioning VP shunts or shunt-related infections must be monitored closely and transported with their heads elevated to a 30° angle. The head should be maintained in a neutral position, and the child should be kept as calm as possible. Monitor the pulse oximetry as well as the $ETCO_2$ level (if available). Maintaining a slightly decreased $ETCO_2$ level and increased oxygenation can aid in decreasing cerebral blood flow.

In the event of a VP shunt infection or malfunction in which intracranial pressure (ICP) must be decreased and monitored closely, an external ventricular drain (EVD) may be inserted via a surgical procedure **FIGURE 25-28**. Such a device presents several risks—namely, worsening infection, CSF overdrainage or underdrainage, inadvertent disconnection, or bleeding. The chamber of the EVD must be hung at a specific level (measured in millimeters of mercury [mm Hg]). The zero point is placed at the level of the foramen of Monro. The drainage system is then opened as directed by the neurosurgeon and as needed to maintain a normal ICP of approximately 10 to 20 mm Hg. The CCTP must monitor any patient with an EVD closely for signs and symptoms of increased or even decreased ICP. Close monitoring of vital signs, especially BP, pulse oximetry, and $ETCO_2$ level, is essential. CCTPs must follow their agency's policies and procedures regarding the care of patients with shunts and EVDs.

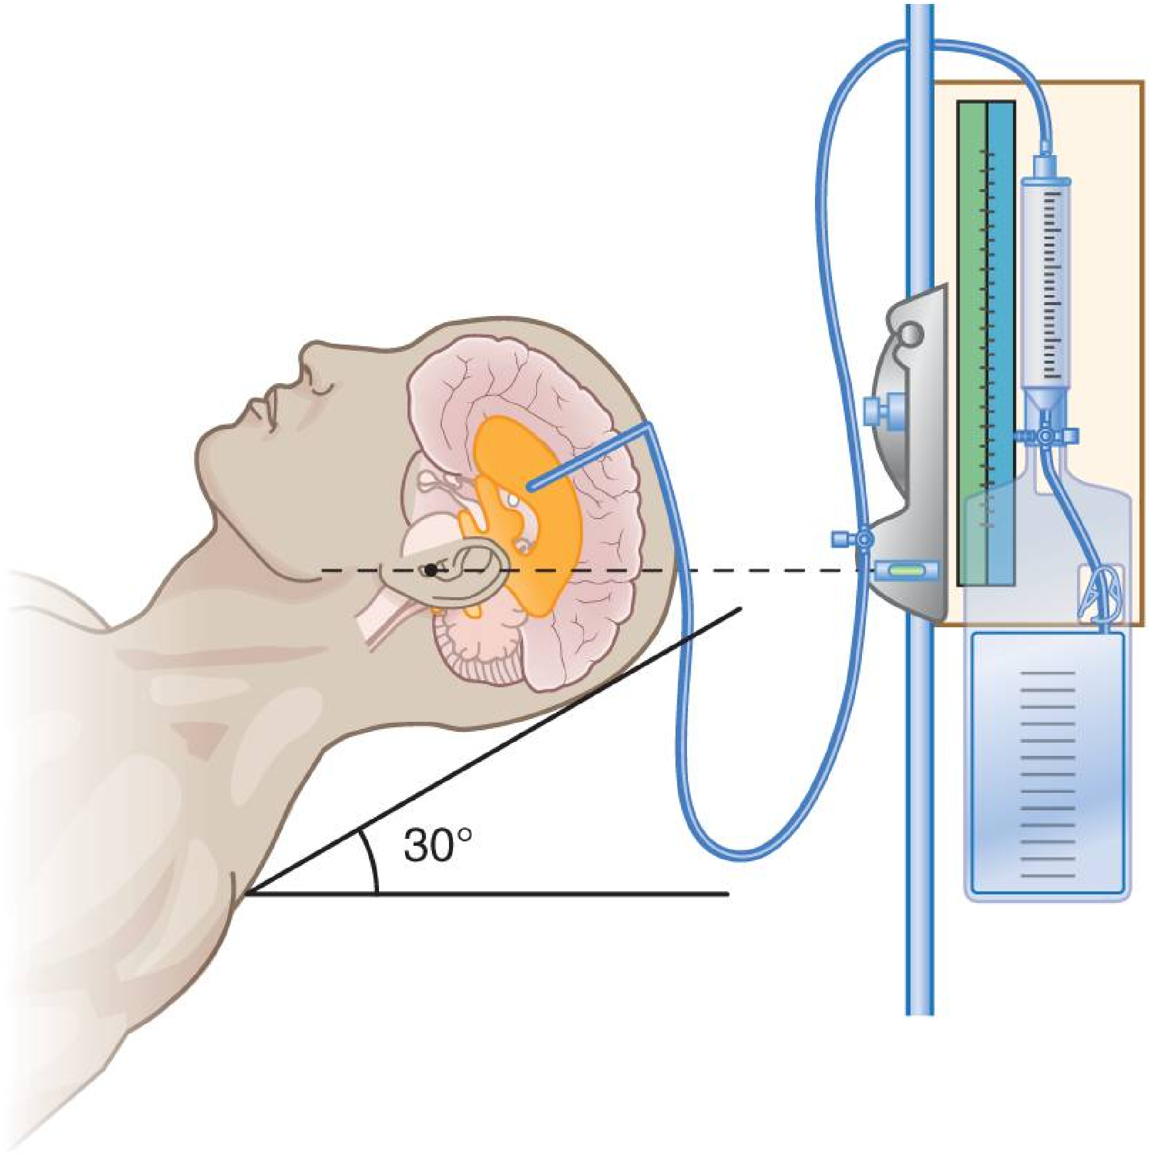

FIGURE 25-28 An external ventricular drain.

Pediatric Patients With Gastrointestinal Disorders

Gastrointestinal disorders that may afflict children and create the need for medical technology include failure to thrive, craniofacial abnormalities, esophageal atresia, burns, strictures, chronic malabsorption, and even gastroesophageal reflux disease (GERD).

Infants and children with Hirschsprung disease, Crohn disease, necrotizing enterocolitis, or imperforate anus may require colostomy or ileostomy placement.

GERD is defined as the complications associated with the reflux of gastric contents into the esophagus. This reflux can cause discomfort, and infants can present with excessive crying, irritability, emesis, and regurgitation. Causes of this condition include obesity, neurologic impairment, prematurity, and hiatal hernia, among others. Severe complications of GERD include esophageal stricture, failure to thrive, aspiration pneumonia, and acute life-threatening events. It is important for the CCTP to transport these patients in a sitting position or upright position to help prevent regurgitation. In severe cases, children with GERD may require gastric tube placement for feedings until the Nissen fundoplication surgical procedure can be performed.

CCTPs may also come in contact with children who have gastrointestinal disorders that render them unable to take in food or formula by mouth. These children may have gastric, gastrostomy, or jejunostomy tubes in place.

- *Gastric tubes* consist of nasogastric or orogastric tubes that pass through the nose or mouth into the stomach **FIGURE 25-29**. They are temporary due to the irritation they cause to the nasal and mucous membranes, but will remain in place for several weeks.
- *Gastrostomy tubes* are inserted directly into the stomach surgically via a tube or button **FIGURE 25-30**. Percutaneous endoscopy gastrostomy tubes are similar but are inserted endoscopically.
- *Jejunostomy tubes* are surgically placed through the stomach and into the small intestine **FIGURE 25-31**. These tubes may be necessary for children who are unable to tolerate feeds through their gastrostomy tube due to reflux, malabsorption, or other reasons. For the same reason, a small-bore nasal feeding tube may be placed into a post-pyloric position. Because they bypass

the stomach and go into the small intestine, jejunostomy tubes can take in volumes only at a very low rate.

- A combination of the gastrostomy and jejunostomy tubes, called a GJ tube, is often the tube used in children. It will have two ports: Medications go through the stomach to be appropriately activated and absorbed, and larger volumes, such as feeds and fluids, go through the jejunostomy portion.

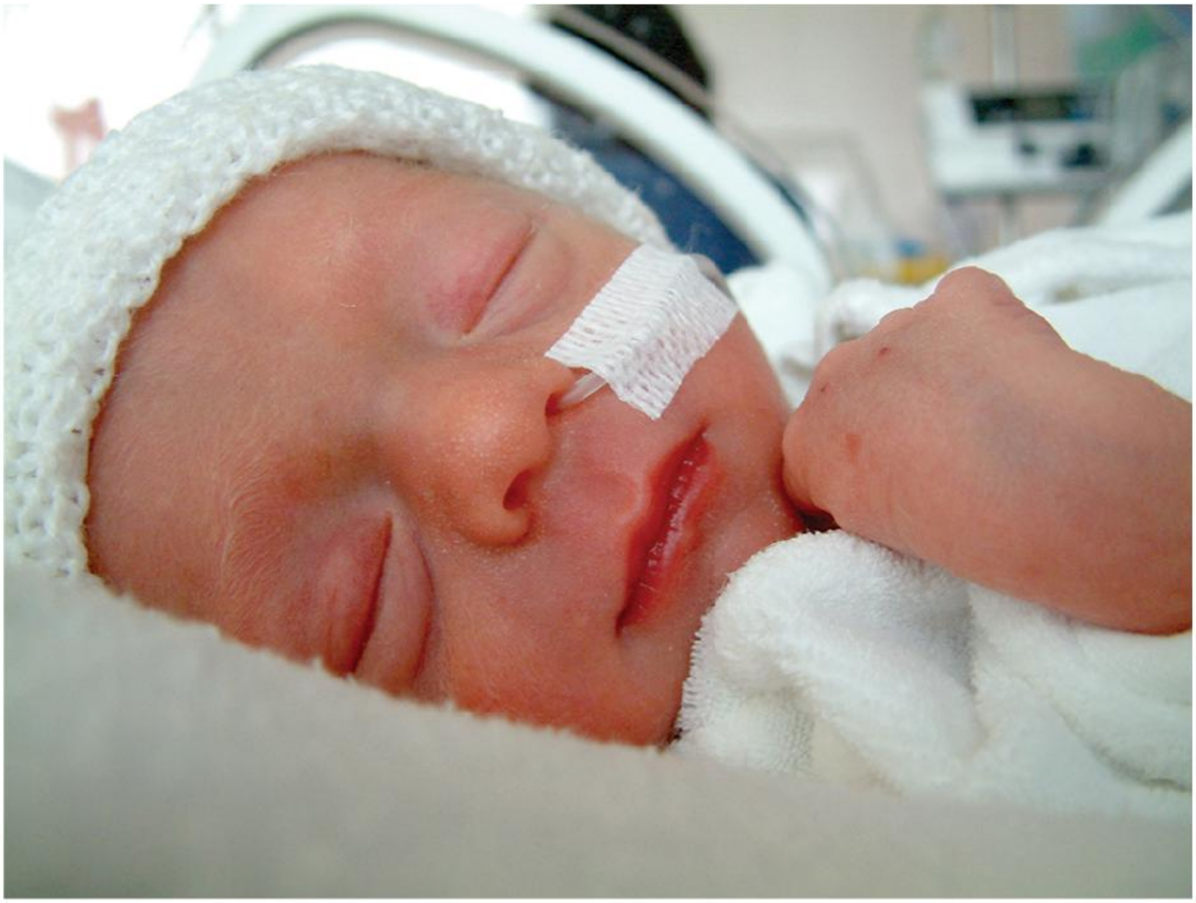

FIGURE 25-29 A nasogastric tube.

© Mediscan/Alamy Stock Photo.

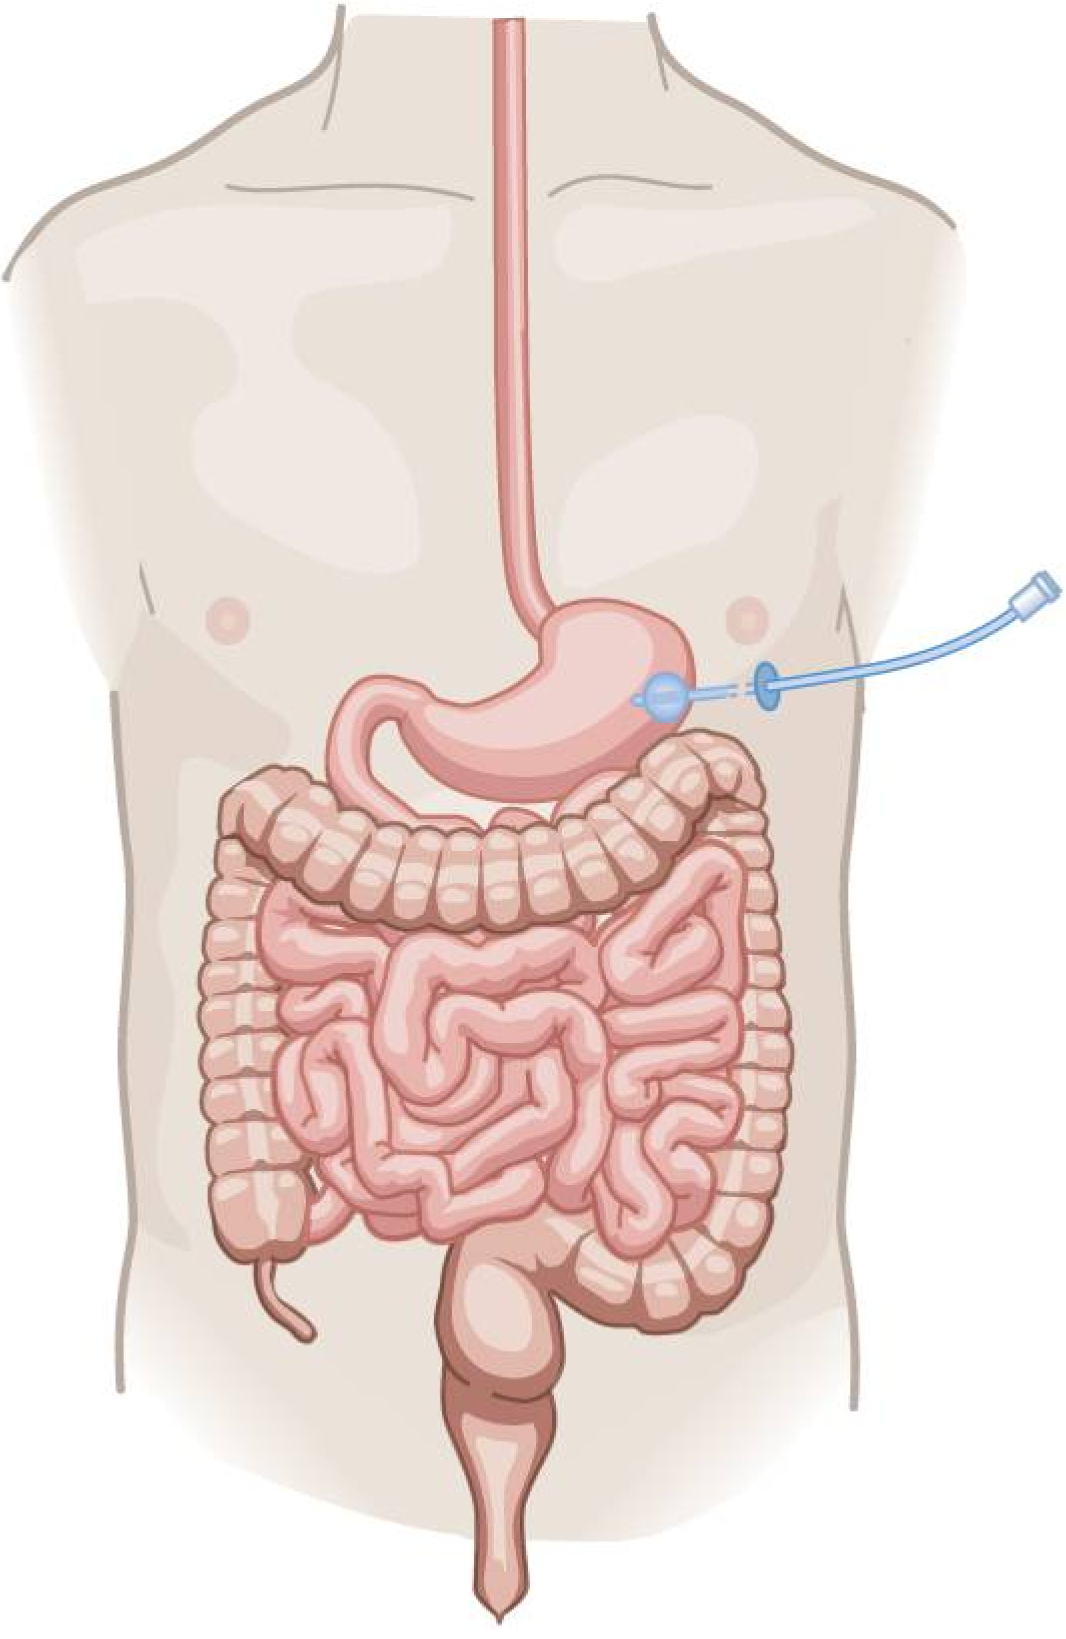

FIGURE 25-30 A gastrostomy tube.

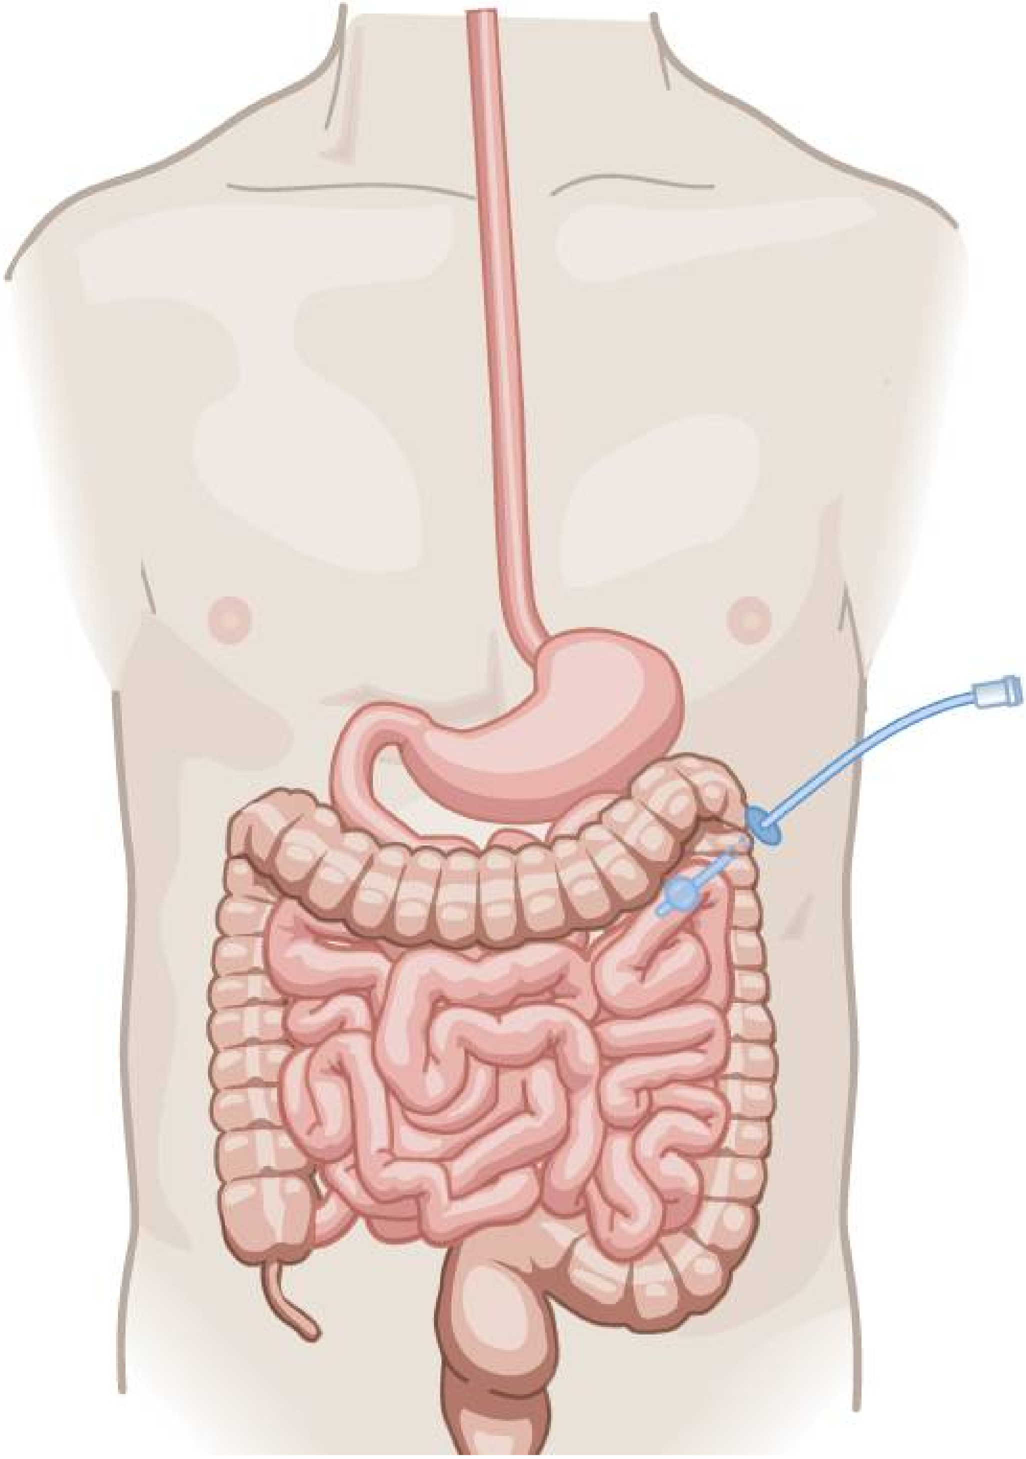
© Jones & Bartlett Learning.



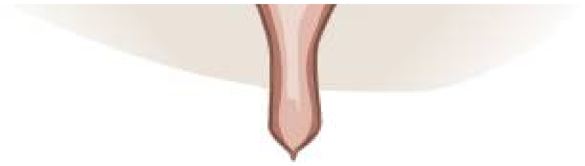


FIGURE 25-31 A jejunostomy tube.

© Jones & Bartlett Learning.

Complications that may be encountered with these devices include the accidental removal of the gastrostomy tube. In such a case, if protocols allow, an indwelling urinary (Foley) catheter may be placed into the abdominal stoma to maintain the patency of the stoma until the gastrostomy tube can be replaced. This complication is of particular urgency if the surgical tract is “immature,” typically meaning the tube was placed less than 6 weeks earlier. It is classically thought that these tracts can close in as little as 4 hours, so it is important to immediately maintain their patency. For this reason, caregivers often will have an extra tube on hand to replace the dislodged tube until definitive replacement can be performed in the hospital. Proper position of the tube should be radiographically confirmed before restarting feeds or delivering medications into a tube that has been replaced. The insertion sites of gastrostomy and jejunostomy tubes must be closely monitored for signs of infection, redness, excoriation, foul drainage, and inflammation.

Children who have colostomy or ileostomy drainage bags in place must be closely monitored for skin infection and breakdown. Colostomy and ileostomy placement increases the risk for skin breakdown due to proteolytic enzymes in the liquid stool coming in contact with skin. The ostomy bags must be well fitted to protect the skin from contact, yet loose enough to not constrict the exposed intestines.

Special Considerations With Pediatric Patients

CCTPs often come in contact with patients who have developmental or cognitive disabilities. The illness or injury that prompted the dispatch may not be a direct result of the patient’s disability, but CCTPs must be able to communicate effectively with the parents and/or caregivers, and understand that the patient may or may not be able to communicate effectively with them. The parents and/or caregivers will be the best source of information in regard to how the patient normally responds. Obtaining an accurate history is vital in determining a baseline for these patients. Providers should not assume that a patient cannot understand language or communicate simply because they are not producing normal speech. Many patients communicate with communication boards or devices.

Patients with Down syndrome also warrant special consideration. These children are often difficult to intubate due to their disproportionately large tongue. Additionally, any patient with a congenital anomaly that results in a small jaw should be considered to have a difficult airway.

Considering that nearly 1 in every 10 births in the United States is premature, CCTPs are likely to encounter infants on apnea monitors. Because apnea monitors record data on events that can later be uploaded into a database at the pediatrician’s office, these devices should be transported with the patient and not removed unless they impede direct patient care.

CSHCN account for approximately 18.5% of all children in the United States. It is important that CCTPs be familiar with these children, who require special attention in the CCT setting. It cannot be overemphasized that the parents and/or caregivers of such patients are the greatest resource that CCTPs have. They will know not only the child’s history, but also the child’s norms, which may be unique. They are the experts in their children’s illnesses, and CCTPs must respect and take into consideration any input they have. As with any pediatric patient, family-centered care is a definite requirement when attending to CSHCN.

Summary

A relatively new area in which CCT units have become involved is the transport of bariatric patients, including those who have undergone bariatric procedures. Following these procedures, patients may require EMS intervention or CCT for either early or late complications. In such cases, the dispatch center or call center should have a detailed protocol for receiving the bariatric transport request, because such transports require specialized equipment and additional personnel, owing to these patients' weight and size. Two basic moves must be carefully planned: (1) moving the patient from the facility bed, chair, or table to the ambulance stretcher, and doing the reverse at the destination; and (2) loading the patient into the ambulance, and removing the patient at the destination. The challenges related to such moves require the CCTP to ensure the safety of both the crew and the patient, while simultaneously guarding the patient's privacy and maintaining good communication.

Excited delirium is a complex condition that can cause severe morbidity and mortality if not rapidly identified and treated. Patients with excited delirium experience symptoms including acute onset of hyperactive, aggressive, and/or combative behavior often associated with excessive physical strength. These symptoms present challenges for CCTPs and may necessitate assistance from law enforcement to maintain safety. Excited delirium is frequently associated with stimulant substance abuse, but may also be linked to underlying psychiatric disease. The primary goals in treating a patient with excited delirium are to protect the patient and providers from injury while maintaining patient dignity, reduce psychomotor agitation, perform a detailed physical exam and continuous monitoring of vital signs, establish IV access, and prevent morbidity and mortality. Treatment of excited delirium focuses on reducing agitation through verbal and environmental de-escalation techniques, administering sedative medications if necessary, correcting hypovolemia with IV volume resuscitation, employing specific therapies targeted at metabolic abnormalities, and preventing unsafe conditions such as transporting the patient in the prone position while handcuffed, or in a position that constricts the chest or neck.

Thanks to the many advances in medicine and technology, some children who would otherwise spend time in the hospital and ICU can be discharged to home with nursing coverage and specialized equipment. These pediatric patients often have congenital illnesses such as heart defects or may have acquired illnesses such as respiratory compromise related to bronchopulmonary dysplasia. Many of them are dependent on technology such as ventilators, tracheostomies, VP shunts, central venous catheters, colostomies, apnea monitors, or gastric tubes. When addressing the needs of these vulnerable patients, CCTPs should recognize that parents and/or caregivers are often the best sources of information.

CASE STUDY

Your ground-based CCT service has been called to a community hospital to transport a 28-year-old man to a tertiary medical center for a higher level of care. The initial dispatch information is vague but suggests that the patient was acting oddly at a community gymnasium, so police were called. A struggle ensued and police requested EMS when they were unable to effectively restrain the patient. On your arrival at the sending facility, you learn that the patient weighs 187 pounds (85 kg) and was sedated in the field by local EMS with 350 mg of ketamine administered IM, followed by several doses of IV midazolam.

Your initial assessment reveals a muscular, incoherent, and profusely diaphoretic 28-year-old man in four-point restraints with a nonrebreathing oxygen mask in place. Despite an oxygen flow of 15 L/min, the oxygen reservoir is completely collapsing with each breath. EMS has established a large-bore IV, currently set at a TKO (to keep open) rate with the initial liter of normal saline, of which approximately 200 mL has been delivered. A second IV is in place, through which an infusion of midazolam is being delivered at 10 mg/h. SpO_2 is 98%; BP is 150/94 mm Hg; heart rate is 155 beats/min with somewhat peaked T waves on the ECG monitor; respirations are 36 breaths/min and deep; and rectal temperature is reported at 102.8°F (39.3°C). Your partner presents you with venous blood gas results that have just been reported, showing pH, 7.0; PO_2, 58 mm Hg; carbon dioxide, 23 mm Hg; bicarbonate, 12 mEq/L; and potassium, 6.1 mEq/L. Lactate is later reported as 16 mg/dL.

The patient is making incomprehensible sounds but is not struggling against the restraints. Your physical exam reveals multiple recent bruises and abrasions consistent with a significant struggle but no major deformity, trauma, or head wounds. A Foley catheter is in place and is draining a scant amount of dark-colored urine.

Following discussion with your partner, you initiate cooling with your transport cooling pads and apply nasal $ETCO_2$, noting a respiratory rate of 38 breaths/min and carbon dioxide of 21 mm Hg. You administer 100 mEq/L of sodium bicarbonate, add 15 L/min of nasal oxygen, and prepare for RSI. Using ketamine and rocuronium, your partner successfully intubates the patient, discontinuing the midazolam infusion in favor of a ketamine infusion for continued sedation. Ventilator settings are adjusted to maintain an end-tidal pressure of 20 mm Hg, an esophageal temperature probe is placed that now reads 102.4°F (39.1°C), and transport is begun. Restraints are double-checked to assure safety and adequate distal perfusion.

During transport, you closely monitor the ECG for changes, add bicarbonate to the normal saline infusion, and increase the fluids to 800 mL/h, which markedly improves the patient's urine output. After 50 minutes, the patient's BP is 140/85 mm Hg; heart rate is 140 beats/min; SpO_2 is 97% on a fraction of inspired oxygen (FIO_2) of 0.3; esophageal temperature is 101.8°F (38.8°C); the patient is breathing spontaneously at 34 breaths/min (with the ventilator now set at 32 breaths/min in pressure control mode); $ETCO_2$ is 18 mm Hg; and urine output for the hour appears to be approaching 80 mL. You deliver the patient to the ED staff at the tertiary hospital and deliver your patient care report.

1. What was the rationale for RSI and why was ketamine selected for induction?
2. How was the end-tidal target determined?

Analysis

Excited delirium is a life-threatening syndrome with a high mortality rate, even when recognized and promptly treated. Metabolic acidosis associated with the hypermetabolic state of excited delirium results in compensatory Kussmaul respirations with increased minute volume. Hyperthermia, lactic acidosis, and excess myoglobin result in renal damage and require volume replacement to correct hypovolemia, correction of acidosis via respiratory and pharmacologic therapies, and rapid treatment with sedatives to reduce agitation. IM and/or intranasal sedative medications are commonly used initially to ensure patient and provider safety, followed by active cooling and additional sedation to lessen agitation.

Rhabdomyolysis and profound metabolic acidosis require early and aggressive IV fluid resuscitation as well as administration of IV bicarbonate. Hyperthermia should be treated with cooling measures and benzodiazepines if agitation persists. RSI and mechanical ventilation should be used only if all other interventions have failed and the patient either becomes apneic after sedative medications have been administered or has signs of impending respiratory failure. Caution must be exercised not to reduce the native minute volume being used to compensate for the underlying metabolic acidosis. Hence, after the drive to breathe is eliminated with RSI, providers must attempt to match or slightly surpass the preintubation $ETCO_2$ level. Failure to do so risks worsening the metabolic acidosis, which can rapidly lead to sudden cardiac collapse and death.

Ketamine is effective as both a sedative in excited delirium and an induction agent for intubation because it can be administered by either the IM or IV route and has a rapid onset without the hypotensive or negative inotropic effects often seen with benzodiazepines or narcotics.

PREP KIT

Ready for Review

- In the United States, more than 40% of adults have obesity. The trend toward greater levels of obesity has been accompanied by a rise in the number of bariatric (weight-loss) procedures performed.
- Several types of bariatric procedures are currently performed, including laparoscopic adjustable banding, vertical banded gastroplasty, sleeve gastrectomy, biliopancreatic diversion with duodenal switch, Roux-en-Y anastomosis, and intragastric balloon.
- Laparoscopic adjustable gastric banding is the least invasive bariatric surgical procedure; it may be performed using either five incisions or one incision.
- Vertical banded gastroplasty, also known as vertical sleeve gastrectomy, is the first part of a biliopancreatic diversion with duodenal switch procedure.
- Biliopancreatic diversion with duodenal switch is a two-part procedure that requires reshaping of the stomach and bypassing of a large portion of the small intestine.
- Roux-en-Y, one type of gastric bypass, is the most common type of bariatric procedure. In this two-part procedure, the stomach is reduced to a holding volume of approximately 30 mL (or the size of a walnut), and then the small intestines are divided and the jejunum is connected to a small hole in the stomach pouch.
- Early complications of bariatric procedures are those that occur within the first month after the procedure, such as deep vein thrombosis, pulmonary embolism, wound infection, sepsis, and gastrointestinal bleeding.
- Late complications of bariatric procedures occur more than 1 month after the procedure, such as obstruction from strictures,

hernias, or hardware complications.

- Other specific bariatric procedural complications include band erosion, band intolerance, band slippage, port flip/inversion or dislodgement, and port dislocation.
- In patients with morbid obesity and those who have undergone bariatric surgery, both oxygen consumption and carbon dioxide production are increased. The increase in oxygen consumption may necessitate the use of a full main cylinder or the inclusion of additional oxygen cylinders on the transport unit, depending on the patient and the length of transport or time spent on the stretcher.
- The dispatch center or call center should have a detailed protocol for receiving bariatric transport requests, including obtaining information on the patient’s height and weight.
- In bariatric transports, time on task will be significantly increased. Operationally, the agency must be prepared for this extended duration and the deleterious effects it may have on the transport service’s system-wide performance and availability of resources.
- Two basic moves must be planned for when transporting bariatric patients:
  - Moving the patient from the facility bed, chair, or table to the ambulance stretcher, and doing the reverse at the destination
  - Loading the patient into the ambulance, and removing the patient at the destination
- A slide board is a basic device that is specifically used when movement of the patient from one level surface to another surface of similar height is indicated, typically from the bed to treatment table to the ambulance stretcher.
- Hydraulic and mechanical lift devices are most often seen in hospitals, surgical centers, skilled nursing facilities, and rehabilitation facilities.
- Air transfer mats work similarly to slide boards, in that they are used to laterally transfer patients, regardless of their size, from one level surface to another at a similar height.

- Bariatric-model stretchers are rated for a higher capacity and size; they are made with stronger construction and are considerably wider to ensure the patient’s comfort.
- Many transport services have deployed a ramp and winch system in specific vehicles designated for the transportation of bariatric patients.
- Strictly because of their sizes, bariatric patients require special considerations when being prepared for transport. Covers will need to be larger, and patient adjustment on an ambulance stretcher may be difficult.
- Accommodating bariatric patients requires special considerations and proper communication. The patient has likely learned ways to deal with these challenges and can assist providers in helping with moving, positioning, and other transport issues.
- When transporting a bariatric patient, it is of utmost importance that the patient’s dignity and privacy are protected.
- Safety during bariatric transports is a paramount concern for both providers and patients. Special devices such as ceiling harnesses, emergency lifting cushions, patient boosters, and motorized wheelchairs and bed movers may be available to reduce the risk of injury, and additional personnel may be needed.
- Patients with excited delirium, also called agitated delirium, experience both delirium (acute confusion, hallucinations, and disorientation that is rapid in onset and may fluctuate in intensity) and an excited or agitated state. Symptoms include acute onset of hyperactive, aggressive, and/or combative behavior often associated with excessive physical strength.
- Patients with excited delirium have high rates of recent sympathomimetic or hallucinogenic recreational drug use, but may also present with or without drug use in the setting of acute decompensated psychiatric illness, such as schizophrenia or bipolar disorder.
- Even with prompt and appropriate treatment, excited delirium has a high mortality rate; nevertheless, rapid, targeted treatment

greatly improves outcomes, decreasing both morbidity and mortality.

- Risk factors that appear to predispose an individual to developing excited delirium include male sex, use of stimulant drugs, and underlying psychiatric disease.
- Excited delirium is characterized by abnormal neurotransmitter physiology in the brain, including increased concentrations of the catecholamine dopamine.
- In the hypermetabolic state associated with elevated dopamine levels, sympathomimetic effects associated with excited delirium include tachycardia, hypertension, and elevated temperature. Oxygen supply–demand mismatch can occur, leading to severe lactic metabolic acidosis from anaerobic metabolism.
- Renal failure in patients with excited delirium results in accumulation of waste products in the blood, hyperkalemia, and metabolic acidosis. The combination of these factors places the patient at high risk for cardiac arrhythmias and death.
- It can be difficult to differentiate excited delirium from other diagnoses without a thorough evaluation, but such an evaluation can be nearly impossible to perform prior to pharmacologic sedation due to the risk of injury to health care providers and the patient. Often, only a very limited history can be obtained due to the patient’s altered mental status.
- In suspected excited delirium, a 12-lead ECG can be useful to detect QTc interval prolongation, QRS complex widening, cardiac ischemia, and evidence of hyperkalemia.
- Laboratory evaluation of a patient with excited delirium may reveal a severe anion gap metabolic acidosis, a nonspecific leukocytosis, elevated troponin levels, elevated creatine kinase levels, myoglobinuria, hyperkalemia, and potentially acute renal failure with an elevated creatinine level.
- The primary goals of treatment of a patient with excited delirium are to protect the patient and healthcare providers from injury while maintaining patient dignity, reduce psychomotor agitation,

facilitate a detailed physical exam and continuous monitoring of vital signs, establish intravenous (IV) access, and prevent morbidity and mortality. Treatment of excited delirium focuses on reduction of agitation through verbal and environmental de-escalation techniques, the use of sedative medications if necessary, correction of hypovolemia with IV volume resuscitation, specific therapies targeted at metabolic abnormalities, and the prevention of environmental conditions that increase mortality.

- It is frequently not possible to safely establish IV access during the primary assessment of a patient with excited delirium, and initial sedation must be achieved via the intramuscular route. The most commonly used medications for this purpose include benzodiazepines, antipsychotics, and ketamine. Rapidly dissolving second-generation antipsychotics, such as olanzapine, are another effective option.
- When they experience a prolonged state of psychomotor agitation, patients with excited delirium may become dangerously hyperthermic, and cooling may be required.
- The treatment of rhabdomyolysis emphasizes aggressive IV volume resuscitation and urine output monitoring to maintain adequate renal perfusion and reduce the risk of kidney damage.
- Patients being transported with excited delirium should be placed on continuous cardiopulmonary monitoring, including electrocardiogram, pulse oximetry, end-tidal carbon dioxide, and body temperature readings. Critical care transport professionals (CCTPs) should not use handcuffs or other locked physical restraints unless required by law enforcement, in which case a key and the law enforcement officer should accompany the patient at all times. Patients should never be transported in the prone position, with hands and feet tied together behind their back, or in a position that constricts the chest or neck.
- Children with special health care needs (CSHCN) are defined by the US Department of Health and Human Services as “those who have or are at increased risk for a chronic physical,

developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally."

- Many children who would otherwise spend time in the hospital and intensive care unit are now able to be discharged to home with nursing coverage and specialized equipment (eg, ventilators, tracheostomies, ventriculoperitoneal shunts, central venous catheters, colostomies, apnea monitors, or gastric tubes). These children often have congenital illnesses such as heart defects or may have acquired illnesses such as respiratory compromise related to bronchopulmonary dysplasia.
- The clinical consequences of congenital heart defects (CHDs) are heart failure and hypoxemia.
- Classification of CHDs is currently based on hemodynamic characteristics and consists of four categories: (1) increased pulmonary blood flow; (2) decreased pulmonary blood flow; (3) mixed blood flow; and (4) obstructive blood flow out of the heart.
- Acyanotic defects are usually caused by increased pulmonary blood flow and obstructive blood flow out of the heart; cyanotic defects consist of decreased pulmonary blood flow and mixed blood flow.
    - The increased pulmonary blood flow classification for acyanotic defects includes defects that cause a left-to-right shunt and can cause heart failure: atrial septal defect, ventricular septal defect, atrioventricular canal defect, and patent ductus arteriosus.
    - Acyanotic defects associated with obstructive blood flow include coarctation of the aorta, aortic stenosis, and pulmonic stenosis.
    - Cyanotic defects associated with decreased pulmonary blood flow include tetralogy of Fallot and tricuspid atresia.
    - The mixed blood flow classification of cyanotic defects consists of transposition of the great vessels and hypoplastic left heart syndrome.

- Some CHDs, such as coarctation of the aorta and hypoplastic left heart syndrome, require patency of the ductus arteriosus for survival. Administration of oxygen must be approached cautiously in infants with CHDs, as it may be fatal by promoting closure of the patent ductus arteriosus.
- IV fluid administration must be used cautiously in pediatric patients with CHDs. While most children can handle an IV bolus of 20 mL/kg, these vulnerable patients must be closely monitored and given only 10 mL/kg to prevent fluid overload or pulmonary edema.
- Pulse oximetry and blood pressure readings from both the upper and lower extremities can yield valuable clues to the presence of a CHD in pediatric patients.
- Children with sickle cell anemia often present with chest pain, extremity pain, and difficulty breathing. In the worst-case scenario, they may have a cerebral vascular accident.
- When children present in sickle cell crisis, aggressive treatment is necessary. These patients require oxygenation, an IV fluid bolus of isotonic crystalloids, or, if tolerated, oral rehydration. In severe cases, children may require blood transfusions.
- Pain management is extremely important for patients in sickle cell crisis, as is monitoring of respiratory status to assess for pneumonia.
- When faced with an injury to a child with hemophilia, first and foremost the CCTP must treat any obvious bleeding. These children require immediate administration of factor VIII intravenously.
- Venous access devices include tunneled catheters, implanted ports, and peripherally inserted central catheters. Depending on the specific catheter, the smallest syringe the CCTP may be able to use with these devices might be a 10-mL syringe.
- Bronchopulmonary dysplasia and tracheomalacia are commonly encountered respiratory disorders that may require or be the

result of long-term ventilation, endotracheal tube placement, or tracheostomy placements in pediatric patients.

- Children with bronchopulmonary dysplasia may require tracheostomies, mechanical ventilation, and end-tidal carbon dioxide monitoring.
- Placing infants and children with tracheomalacia in a prone position allows gravity to assist in opening the airway; the supine position is dangerous in these patients due to the risk of narrowing of the weakened trachea or even airway collapse.
- When changing the tracheostomy tube, the CCTP should place a towel roll under the patient’s shoulders (which puts the child into the “sniffing” position and allows for easier insertion of the tracheostomy tube), ensure that the cuff is not overinflated, and administer only warmed, humidified oxygen via an oxygen warming device or a humidivent attachment.
- When caring for children with a tracheostomy tube, the CCTP should ensure that an obturator, an extra tracheostomy tube of the same size, and a tracheostomy tube of a size smaller are readily available in case the tube is accidentally pulled out of place.
- Children with hydrocephalus will present with abnormally large heads, poor feeding, restlessness, bulging fontanelles, shrill or shrieking cry, and inconsolability; they may also have dilated scalp veins. The CCTP will often encounter these children when they have a ventriculoperitoneal shunt malfunction or infection.
- Children with malfunctioning ventriculoperitoneal shunts or shunt-related infections must be monitored closely and transported with their heads elevated to a 30° angle. The head should be maintained in a neutral position, and the child should be kept as calm as possible.
- Children with gastrointestinal disorders who have special devices or needs may have such issues as failure to thrive, craniofacial abnormalities, esophageal atresia, burns, or strictures, or they may experience chronic malabsorption or gastroesophageal reflux disease. Infants and children with Hirschsprung disease, Crohn

disease, necrotizing enterocolitis, or imperforate anus may require colostomy or ileostomy placement.

- In case of the accidental removal of a gastrostomy tube, if protocols allow, an indwelling urinary catheter may be placed into the abdominal stoma to maintain the patency of the stoma until the gastrostomy tube can be replaced.
- The insertion sites of gastrostomy and jejunostomy tubes must be closely monitored for signs of infection, redness, excoriation, foul drainage, and inflammation.
- With pediatric patients who have developmental or cognitive disabilities, CCTPs must be able to communicate effectively with their parents and/caregivers, and understand that the patient may or may not be able to communicate effectively with them. The parents and/or caregivers will be the best source of information regarding how the patient normally responds.
- Patients with Down syndrome are often difficult to intubate due to their abnormally large tongues.
- Apnea monitors should be transported with the patient and not removed unless they impede direct patient care.

Vital Vocabulary

acyanotic defects Congenital heart defects in which blood is shunted from the left heart to the right heart; usually caused by increased pulmonary blood flow and obstructive blood flow out of the heart.

aortic stenosis Narrowing of the aortic valve, which can be described as valvular, supravalvular, or subvalvular.

atrial septal defect (ASD) An opening in the septal wall of the heart between the left and right atria, allowing blood flow from the left atrium to the right atrium.

atrioventricular canal defect An acyanotic heart defect that consists of both ventricular and atrial septal defects as well as a defect affecting the mitral and tricuspid valves, in which the valves are shared.

bariatric procedures Weight-loss procedures that typically involve reconfiguring the stomach and sometimes other portions of the gastrointestinal tract.

biliopancreatic diversion with duodenal switch (BPD/DS) A two-part bariatric surgical procedure that involves reshaping the stomach and bypassing a large portion of the small intestine.

bronchopulmonary dysplasia A chronic lung disorder that usually occurs in premature infants who weigh less than 3 pounds (1,500 g) at birth.

children with special health care needs (CSHCN) As defined by the US Department of Health and Human Services, those children “who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally.”

coarctation of the aorta The narrowing or constriction of part of the aorta or aortic arch of the heart.

cyanotic defects Congenital heart defects that lead to low oxygen saturation, owing to either decreased pulmonary blood flow or mixed blood flow.

delirium Acute confusion, hallucinations, and disorientation that is rapid in onset and may fluctuate in intensity.

dopamine A neurotransmitter that plays important roles in executive function, impulsivity, sensory perception, and key physiologic parameters (eg, heart rate, blood pressure, and temperature regulation).

excited delirium A complex, life-threatening syndrome including both delirium and an excited or agitated state; also called agitated delirium.

heart failure A set of clinical signs and symptoms indicative of myocardial dysfunction and cardiac output that is inadequate to meet the metabolic demands of the body.

hemophilia A disease caused by inheritance of a recessive gene trait that causes excessive bleeding. The resulting factor VIII or factor IX deficiency leaves the blood unable to clot properly.

hydrocephalus The result of an obstruction that causes an excessive accumulation of cerebrospinal fluid.

hyperkalemia Abnormally high potassium concentration in the blood.

hypoplastic left heart syndrome A cyanotic heart defect that is caused by an abnormally small left ventricle; it is often associated with aortic and mitral valve stenosis or atresia.

Kussmaul respiration A typical respiratory pattern seen in patients with metabolic acidosis; it is characterized by a high respiratory rate and high tidal volume, leading to increased minute ventilation.

laparoscopic adjustable gastric banding (LAGB) The least invasive bariatric surgical procedure, in which an adjustable band is placed around the upper portion of the stomach, with an adjustment port located on the right side of the abdomen, under the skin.

morbid obesity A body mass index of 40 kg/m^2 or higher. Morbid obesity includes all of the health risks associated with obesity, but also makes essential functions such as walking or breathing difficult.

neutropenia A decrease in the number of neutrophils in the body; neutrophils are essential in the body’s immune response system.

obesity A body mass index greater than or equal to 30 kg/m^2.

overweight A body mass index of 25 to 29.9 kg/m^2.

patent ductus arteriosus (PDA) An acyanotic heart defect in which blood flows from the aorta to the pulmonary artery.

Pickwickian syndrome A hypoventilation syndrome associated with obesity in which the person may experience increased breathing difficulty when in the supine position and have a higher incidence of sleep apnea, snoring, and hypercapnia.

pulmonic stenosis An acyanotic heart defect caused by obstruction of blood flow from the right ventricle to the pulmonary artery; also called pulmonary stenosis.

rhabdomyolysis A condition in which muscle fibers break down and release their contents (proteins) into the bloodstream.

Roux-en-Y The most common type of bariatric surgery, in which the size of the stomach is reduced, the small intestines are divided, and the jejunum is connected to a small hole in the stomach pouch; also known as gastric bypass.

sickle cell anemia A disease caused by inheritance of two sets of recessive genes that produce an abnormal hemoglobin protein, known as Hgb S. The red blood cells become deformed (have a sickle shape) and occlude vessels, clot, and cause great pain in patients.

sleeve gastrectomy A bariatric surgical procedure that is the first part of a biliopancreatic diversion with duodenal switch procedure, in which the structure of the stomach is changed to a tube; also known as vertical sleeve gastrectomy.

tetralogy of Fallot (TOF) A cyanotic heart defect characterized by four anomalies: ventricular septal defect, pulmonary stenosis, overriding aorta, and right ventricular hypertrophy.

tracheomalacia A weakening or softening of the tracheal cartilage/rings that leads to respiratory disease.

transposition of the great vessels A cyanotic heart defect that results from the aorta receiving blood from the right ventricle while the pulmonary artery leaves the left ventricle.

tricuspid atresia A cyanotic heart defect that results from an absent or defective tricuspid heart valve, which causes blood flow from the right atrium to the right ventricle to be blocked.

ventricular septal defect (VSD) An acyanotic heart defect in which blood flows from the left ventricle to the right ventricle through a hole in the septal wall.

vertical banded gastroplasty (VBG) A bariatric surgical procedure that divides the stomach into two parts; also known as stomach stapling.

GLOSSARY

3-3-2 rule:

A method used to predict difficult intubation; a mouth opening of less than three fingers wide, a mandible length of less than three fingers wide, and a distance from the hyoid bone to the thyroid notch of less than two fingers wide indicate a possibly difficult airway.

abandonment:

The termination of the patient relationship without assurance that an equal or greater level of care will continue.

Abbreviated Injury Scale (AIS):

A trauma scoring system that ranks injury severity by assigning an individual injury score of 1 to 6 to six body regions, with 1 being a minor injury and 6 being an injury with a high mortality rate; does not account for multisystem injuries.

ABCDE:

A mnemonic used to help providers remember the patient assessment sequence: Airway, Breathing, Circulation, Disability, and Exposure.

abdominal compartment syndrome (ACS):

A condition that can result from intra-abdominal hypertension, including decreased end-organ perfusion with evidence of failure; if untreated, it can lead to death.

ablation:

Removal of a pathway or function by electrocautery or radiofrequency.

ABO-incompatible transfusion reactions:

Transfusion reactions in which the patient possesses antigens to a blood type and receives that blood type.

absolute refractory period:

The early phase of cardiac repolarization, wherein the heart muscle cannot be stimulated to depolarize.

absorption:

Acquisition of additional heat, radiation, or other energy from the environment. Also, movement of a substance’s molecules from the site of entry on the body into the systemic circulation; the process by which molecules are taken up into another medium or tissue.

accuracy:

A measure of the likelihood that an average of a set of test values will be similar to the true value.

acetylcholine (ACh):

A chemical neurotransmitter of the parasympathetic nervous system.

acrocyanosis:

A decrease in the amount of oxygen delivered to the extremities. The hands and feet turn blue because of the lack of oxygen.

activated charcoal:

A carbon-based liquid with an incredible adsorptive ability that is typically administered orally or via nasogastric or orogastric tube to decrease the available quantity of a toxic substance.

activated partial thromboplastin time (aPTT):

A value that represents the intrinsic coagulation pathway’s clotting ability; also known as partial thromboplastin time (PTT).

active error:

An error that almost always involves frontline staff and occurs at a contact point between a staff member and some aspect of a larger system.

active immunity:

Production of a specific antibody in response to an infection or antigen.

active warming:

A method of warming a hypothermic patient that involves the introduction of exogenous heat sources to the patient; measures may include infusing warmed IV fluid, delivering warm, humidified oxygen, or administering a peritoneal lavage of a potassium chloride–free solution or nasogastric/orogastric lavage with warmed fluids.

acute coronary syndrome (ACS):

Any group of clinical symptoms consistent with acute myocardial ischemia.

acute glomerulonephritis (AGN):

A histopathologic diagnosis associated with edema, hypertension, and hematuria; results from deposition of circulating immune complexes in the kidney basement membrane, which ultimately causes reduced glomerular filtration.

acute kidney injury (AKI):

Decreased renal function in the absence of preexisting renal disease. It is classified into three categories: prerenal, intrarenal, and postrenal.

acute postinfectious glomerulonephritis (APIGN):

A form of acute glomerulonephritis that occurs following an infection by streptococci.

acute radiation syndrome:

Radiation poisoning.

acute tubular necrosis (ATN):

Damage to the tubules of the nephron, preventing proper ion and fluid exchange in the kidneys.

acyanotic defects:

Congenital heart defects in which blood is shunted from the left heart to the right heart; usually caused by increased pulmonary blood flow and obstructive blood flow out of the heart.

adaptive immune system:

The secondary mechanism that protects the host by reacting with and eliminating specific antigens but that requires more time than the innate immune system to mobilize its defenses against unknown pathogens.

adaptive immunity:

The immunity the body develops as part of exposure to an antigen or through vaccination; also called acquired immunity.

Addison disease:

A chronic hormonal or endocrine disorder caused by a deficiency of cortisol and/or aldosterone; characterized by weakness, fatigue, hypotension, unexplained weight loss, and darkening of the skin.

addisonian crisis:

The sudden appearance of symptoms, especially shock, in a patient with chronic adrenal insufficiency; it may appear suddenly as a result of an increased period of stress, trauma, surgery, or severe infection. Other symptoms include weakness, altered mental status, hyperthermia, and severe pain in the lower back, legs, or abdomen.

adhesions:

Bands of connective tissue that can distort the normal GI anatomy; the result of improper healing or scar tissue growth following surgery.

adrenal insufficiency (AI):

Underproduction of cortisol and aldosterone caused by a decreased function of the adrenal cortex; it occurs when at least 90% of the adrenal cortex has been damaged.

adsorption:

The process of attracting molecules of a substance to the surface of that substance.

adventitious breath sounds:

Abnormal breath sounds that are heard in addition to, or in place of, normal sounds.

adverse drug event (ADE):

An adverse reaction caused by taking a medication.

aerobic metabolism:

A form of energy production in which mitochondria use glucose, amino acids, and fatty acids combined with oxygen and ADP to produce ATP, carbon dioxide, water, and heat.

aerophagia:

A condition in which the stomach fills with excessive air secondary to increased respiratory rate.

afferent pathways:

Ascending pathways that carry sensory impulses toward the central nervous system.

afterload:

The tension or stress that develops in the ventricles during systole; measured by pulmonary and systemic vascular resistance.

agonal respirations:

Slow, shallow, irregular respirations, or occasional gasping breaths; result from cerebral anoxia.

agonist:

A molecule (medication) that binds and activates a receptor, producing a biologic response.

Air Medical Physician Association (AMPA):

An organization of physicians and air medical professionals that promotes safe patient transport.

air medical resource management (AMRM):

The term used in air medical programs to denote the concept of crew resource management—an initiative designed to ensure all parties involved in an operation have decision-making input.

alanine aminotransferase (ALT):

An intracellular enzyme found in large amounts in the liver and kidney, skeletal muscle, and heart; formerly known as serum glutamic-pyruvic transaminase (SGPT).

albumin:

A blood product containing this specific protein found in the blood, which is prepared by the fractionation of pooled plasma; used for volume replacement in certain conditions; the most common protein in the body; acts as a transport protein, is a free radical scavenger, and serves as the main source of protein-generated oncotic pressure.

alcoholic ketoacidosis:

A type of acidosis characterized by a buildup of ketones in the blood, caused by a large intake of alcohol and poor nutritional intake.

aldosterone:

The main hormone responsible for adjustments to the final composition of urine; it increases the rate of active resorption of sodium and chloride ions into the blood and decreases the resorption of potassium.

aldosteronism:

A syndrome of high blood pressure and low blood potassium levels caused by an excess of aldosterone; there are two main types—primary and secondary.

alkaline phosphatase:

An enzyme that is essential for proper digestion and absorption through the mucous membranes in the gastrointestinal tract; it is clinically useful for testing liver function and for diagnosing a common bile duct obstruction.

Allen test:

A technique in which the patient’s hand is initially held above the head while the fist is clenched and the radial and ulnar arteries are compressed; the hand is then lowered and the fist is opened, ulnar pressure is released, and radial pressure is maintained. After the ulnar pressure is released, color should return to the hand within 6 seconds.

alveolar ventilation (V_a):

The volume of air that comes into contact with the alveolar-capillary membrane surfaces and participates in the exchange of gases between the lung and blood.

amniotic fluid embolism (AFE):

A rare and poorly understood condition in which fetal tissue crosses over the placental barrier into the maternal circulation. It can occur antepartum and postpartum and is believed to be associated with an anaphylactoid response leading to multisystem organ failure and disseminated intravascular coagulation.

amylase:

A key enzyme used by the body to metabolize carbohydrates; it is produced primarily by the salivary glands and the pancreas.

amyloidosis:

A group of diseases that result from abnormal deposits of the protein amyloid in various tissues of the body; can occur in a localized area or may be systemic.

anaerobic metabolism:

A less efficient form of energy production in which an alternative pathway converts glucose to pyruvic acid with the simultaneous production of ATP; it also results in the production of lactate.

anaphylactic shock:

A potentially life-threatening allergic reaction that presents with increased general body edema, hypotension, rash, urticaria, anxiety, and warm, flushed skin; a severe hypersensitivity reaction that involves bronchoconstriction and cardiovascular collapse.

anaphylactoid reaction:

A non–IgE-mediated response that causes the rupture of mast cells and basophils, which then release histamine and other defense mediators.

anaphylaxis:

A serious systemic allergic reaction that has a rapid onset and a variable clinical presentation.

anatomic dead space (V_d):

Space in airway structures such as the trachea, bronchi, and bronchioles that does not participate in gas exchange. It is defined physiologically as ventilation without perfusion.

anechoic:

Free from echo.

aneurysm:

A weakened portion of the wall of an artery where the blood creates a localized dilation or bulge; it can involve the intact wall or be classified as dissecting, in which case the artery wall ruptures and blood pools between the inner and outer artery wall.

angiodysplasia:

Deformed submucosal blood vessels in the GI tract that are susceptible to bleeding.

anion:

A negatively charged ion.

anion gap (AG):

A summary of the relationship among the three major contributors to the overall electrical charge (Na^+, Cl^-, and HCO_3^-); abnormal AG values may signal disturbances in the overall electrical and acid–base balance of the serum and presence of disease.

anisocoria:

A condition in which the pupils are not of equal size.

anode:

The electrode in a pacing circuit that is positively charged when current is flowing.

antagonist:

A molecule (medication) that blocks a receptor site from being stimulated by an agonist or other chemical mediators.

antegrade conduction:

Conduction in the normal direction between cardiac structures.

anterior cord syndrome:

Displacement of bony fragments into the anterior portion of the spinal cord, often as the result of flexion injuries or fractures, that disrupts blood flow in the anterior spinal artery.

antiarrhythmic:

A medication used to treat and prevent cardiac rhythm disorders.

anticholinergic syndrome:

A syndrome that occurs following excessive exposure to medications such as antihistamines, atropine, and benztropine (Cogentin), or other substances such as jimson weed, resulting in muscarinic receptor blockade at the CNS and various other organs; characterized by tachycardia, hyperthermia, dilated pupils, warm (or hot) dry skin, ileus, delirium, seizures, hallucinations, and urinary retention.

antigen:

An agent that stimulates the formation of specific protective proteins called antibodies; substance that can create an immune response in the body.

antigenic drift:

A series of small genetic changes in a virus that alter the virus just enough that antibodies generated in previous infections no longer recognize the viral epitopes or surface proteins and, therefore, do not protect the body from the symptoms of a new infection.

antigenic shift:

More drastic genetic changes in a virus, in which the protein structure of one or both of the spike proteins undergoes changes.

antiphospholipid syndrome (APS):

An autoimmune disorder in which antibodies block certain phospholipid-binding proteins that normally protect the body from excessive coagulation.

anxiolysis:

The reduction of anxiety by the administration of an antianxiety agent.

aortic regurgitation:

Backward flow of blood through the aortic valve from the aorta into the left ventricle.

aortic stenosis:

Narrowing of the aortic valve, which can be described as valvular, supravalvular, or subvalvular.

Apgar score:

A scoring system for assessing the status of a newborn that assigns a numerical value to five areas of assessment (the total possible score range is 0–10).

aphasia:

Any loss or impairment of language function as a result of brain damage.

apnea:

Respiratory pause greater than or equal to 20 seconds; the absence of respiration.

apneustic breathing:

A condition in which lesions in the respiratory center of the brainstem lead to a breathing pattern characterized by prolonged, gasping inspiration, followed by extremely short, ineffective expiration.

apoptosis:

Programmed cell death.

appendicitis:

Inflammation and/or infection of the appendix.

arachnoid mater:

The middle layer of the meninges, which contains blood vessels that give it the appearance of a spider web.

arterial blood gas (ABG) panel:

A collection of lab values used to analyze the following characteristics of blood: pH, partial pressure of CO_2 (in arterial blood), partial pressure of oxygen (in arterial blood), concentration of bicarbonate ion, base excess (indicating whether the patient is acidotic or alkalotic), and oxygen saturation of the hemoglobin molecule.

arterial bruits:

Turbulence or “swishing” sounds heard with a stethoscope placed over the carotid arteries that signal the presence of atherosclerosis.

arterial lines:

Catheters inserted into the patient’s arterial vascular system for the purpose of producing a waveform with pressure measurements; also called A-lines.

arterial oxygen content (Cao_2):

The total amount of oxygen in the arterial blood.

arteriovenous malformation (AVM):

A cluster of abnormally formed blood vessels that have a higher rate of bleeding than average vessels.

ascites:

A buildup of fluid in the abdominal cavity.

ascromegaly:

A syndrome that results from excessive secretion of growth hormone by the pituitary gland after the epiphyseal plate has closed; characterized by the growth of bones, muscles, and many internal organs at an abnormally fast rate.

aspartate aminotransferase (AST):

An intracellular enzyme found in large amounts in the liver and in skeletal muscle, the brain, red blood cells, and the heart; formerly known as serum glutamic-oxaloacetic transaminase (SGOT).

assault:

The unlawful act of placing a person in apprehension of immediate bodily harm without their consent.

assisted systole:

The pressure waveform that follows the diastolic augmentation peak.

assist ratios:

Settings on the intra-aortic balloon pump that allow the operator to determine how often the pump inflates the balloon.

atelectasis:

Collapse of all or part of a lung.

atmosphere:

Gases that extend from the earth’s surface to space; composed primarily of nitrogen, oxygen, argon, and trace gases.

atresia:

Complete absence of a lumen.

atrial septal defect (ASD):

An opening in the septal wall of the heart between the left and right atria, allowing blood flow from the left atrium to the right atrium.

atrioventricular (AV) valves:

The valves (mitral and tricuspid) that separate the atria from the ventricles.

atrioventricular canal defect:

An acyanotic heart defect that consists of both ventricular and atrial septal defects as well as a defect affecting the mitral and tricuspid valves, in which the valves are shared.

autonomic dysreflexia:

A potentially life-threatening complication of spinal cord injury that results from the loss of parasympathetic stimulation. It is characterized by a massive, uninhibited, uncompensated cardiovascular response as the result of some stimulation of the sympathetic nervous system below the level of injury; also called autonomic hyperreflexia.

auto-PEEP:

The nonintended increase in end alveolar pressure due to air trapping.

AVPU scale:

An evaluation tool used to determine patient responsiveness; stands for Alert, responds to Voice, responds to Pain, Unresponsive.

axonal transport:

The movement of organelles and proteins along a nerve cell axon into and out of the cell body.

azotemia:

Increased nitrogenous wastes in the blood.

azygos system:

A network of blood vessels that connects the superior and inferior vena cava; it also drains a portion of the esophageal venous blood.

bacteremia:

The presence of bacterial infection in the blood.

bactericidal:

Capable of killing bacteria.

bacteriostatic:

Capable of inhibiting bacterial growth.

bandemia:

Release of excessive numbers of band cells from the bone marrow into the blood.

bariatric procedures:

Weight-loss procedures that typically involve reconfiguring the stomach and sometimes other portions of the gastrointestinal tract.

barodontalgia:

A condition caused by ambient pressure changes that may result from gas bubbles trapped below the gums during restorative dental treatments, from periodontal cysts or abscesses; previously referred to as flyer’s toothache.

barometric pressure:

The weight per unit area of all the molecules of the gases above the point at which the measurement was taken.

barosinusitis:

An inflammation of one or more of the paranasal sinuses resulting from a pressure gradient between the sinus cavity and atmosphere.

barotitis media:

Inflammation and possible petechial hemorrhage in the middle ear and possible rupture of the eardrum that results from the failure of the middle ear space to ventilate when going from low to high atmospheric pressure; also known as ear block.

barotrauma:

Injury to the chest or lungs as a result of increased intrathoracic pressure; injury to tissues, organs, or structures within the body, resulting from rapid or significant changes in environmental air pressure.

basal ganglia:

Masses of nuclei located deep in the cerebral hemispheres that play a major role in fine motor function.

basal metabolic rate (BMR):

The heat energy produced at rest by normal body metabolic reactions, determined mostly by the liver and skeletal muscle.

base excess (BE):

A measure of metabolic derangement that is part of the arterial blood gas panel; also known as base deficit (BD), as the value can be either positive (excess) or negative (deficit).

basilar skull fracture:

A fracture along the base of the skull.

battery:

The unlawful touching of another person without their consent.

Battle sign:

Migration of blood to the mastoid region, posterior and slightly inferior to the ear, resulting in discoloration; also called retroauricular ecchymosis.

Beck triad:

The combination of a narrowed pulse pressure, muffled heart tones, and jugular venous distention associated with cardiac tamponade; usually resulting from penetrating chest trauma.

Benchmarking:

The process of comparing an organization’s processes and performance to those of the overall industry or the best practices from other companies.

bicarbonate (HCO_3^-):

An ion that is present in the blood; its measurement represents the metabolic component of the arterial blood gas panel.

bicarbonate–carbonic acid buffer system:

The principal extracellular buffer system, which operates primarily in the lungs and kidneys; in this system, carbon dioxide and water are reversibly converted into carbonic acid, which in turn is reversibly converted into hydrogen ions and bicarbonate.

bifascicular block:

The combination of a right bundle branch block and a block of one of the fascicles of the left bundle, the left anterior or left posterior fascicle.

bilevel positive airway pressure (BPAP):

The use of two separate pressures—inspiratory positive airway pressure and expiratory positive airway pressure—to raise the breathing baseline above the ambient pressure. The pressure gradient enhances ventilation, and the reduced expiratory pressure makes exhalation easier and increases patient tolerance.

biliopancreatic diversion with duodenal switch (BPD/DS):

A two-part bariatric surgical procedure that involves reshaping the stomach and bypassing a large portion of the small intestine.

bilirubin:

A waste product of heme formed during erythrocyte metabolism. It is moved to the small intestine within bile and then converted into urobilinogen, resulting in brown pigmented feces.

bioavailability:

The amount or percentage of a medication that reaches the systemic circulation without being altered.

Biot (ataxic) respiration:

Breathing characterized by three patterns: (1) slow and deep, (2) rapid and shallow, and (3) apnea. Causes include meningitis, increased intracranial pressure, and central nervous system dysfunction.

biotransformation:

The process by which the body alters a medication.

biphasic:

A descriptor for a wave with negative and positive components; typically used in conjunction with P and T waves.

bipolar lead:

A conduction lead comprising two electrodes attached at specific body sites with different polarity, which is used to examine electrical activity by monitoring changes in the electrical potential between those sites.

bipolar system:

A closed system consisting of bipolar leads and a module to generate impulses and measure response.

blood–brain barrier:

A network of endothelial cells and astrocytes (neuroglia) in the brain that regulates the transport of nutrients, ions, water, drugs, and waste products to and from the brain through the process of selective permeability.

blood urea nitrogen (BUN):

A test used to measure urea, which is a biomarker for adequate kidney function.

blood urea nitrogen:creatinine (BUN:CR):

A calculated index used to determine the cause of increased levels of blood urea nitrogen and creatinine.

body packers:

People who swallow carefully prepared packages of illicit substances for smuggling purposes.

body stuffers:

People who hastily swallow poorly packaged illicit substances (often to avoid impending arrest).

Boerhaave syndrome:

Esophageal rupture, associated with subcutaneous emphysema, chest pain, and vomiting.

Boyle's law:

A gas law stating that the volume of a gas is inversely proportional to the pressure to which it is subjected. Gases trapped in body cavities will expand with increases in altitude and will contract with decreases in altitude.

bradypnea:

A respiratory rate that is slower than normal.

brain herniation:

Displacement of a portion of the brain from its correct location within the cranial cavity to a different location.

brain tissue compliance:

The change in brain volume resulting from a change in pressure.

brain tissue oxygen tension ($P_{br}O_2$):

A method of monitoring temperature and oxygenation via placement of a commercial probe into the brain tissue through a bolt; it can be done simultaneously with ICP monitoring placement.

breach of duty to act:

A case in which a health care provider does not conform to the standard of care by providing inappropriate care, failing to act, or acting beyond the scope of practice.

breech:

A delivery presentation in which the presenting part is not the head.

bridge to recovery (BTR):

A treatment objective in which a left ventricular assist device is implanted in a patient as mechanical circulatory support until the native heart recovers its pumping ability.

bridge to transplantation (BTT):

A treatment objective in which a left ventricular assist device is implanted in a patient as mechanical circulatory support to prolong life until a heart transplant can be secured.

Broca area:

Part of the frontal lobe that is located at the inferior frontal gyrus and that participates in the formulation of words.

bronchiolitis:

A condition seen in children younger than 2 years, characterized by dyspnea and wheezing.

bronchopulmonary dysplasia:

A chronic lung disorder that usually occurs in premature infants who weigh less than 3 pounds (1,500 g) at birth.

bronchovesicular sounds:

A combination of the tracheal and vesicular breath sounds, heard in places where airways and alveoli are found, including the upper part of the sternum and between the scapulae.

Brown-Séquard syndrome:

Loss of function as a result of penetrating trauma accompanied by hemisection of the spinal cord and complete damage to all spinal tracts on the involved side; it is characterized by loss of motor function and sensation of light touch, proprioception, and vibration on the ipsilateral side and loss of temperature and pain sense on the contralateral side.

Brudzinski sign:

Passive flexion of the legs and thighs when the examiner flexes the patient’s neck to the chest. If this causes pain or causes the knees and hips to flex involuntarily, the sign is positive.

B-type natriuretic peptide (BNP):

A polypeptide whose value is indicative of abnormal ventricular function and congestive heart failure.

buffer:

Any substance that can alternately bind or release hydrogen ions depending on the outside conditions.

bundle branch block (BBB):

A disturbance in electric conduction through the right or left bundle branch from the bundle of His.

business associate:

As defined under HIPAA, a person or entity, other than a covered entity, who performs activities on behalf of, or provides services to, a covered entity that involves access to protected health information.

cable:

The physical wire that connects the electrode to the electrocardiography monitor.

caloric test:

A method for assessing vestibular function that involves the raising and lowering of the temperature in the external auditory canal; also called Bárány test.

capillary refill time (CRT):

The time it takes for baseline skin color to return to the nail bed after being pressed by the provider; serves as a window into the state of peripheral perfusion.

capnography:

A method for measuring exhaled CO_2, which in most cases correlates with the CO_2 levels in arterial blood. Two different types of devices can be used—an electronic monitor that displays a waveform and a colorimetric device that should turn yellow during exhalation, indicating proper tube placement.

capnometry:

A method for measuring exhaled CO_2; it is performed the same way as capnography, but provides a light-emitting diode readout of the patient’s exhaled CO_2.

caput succedaneum:

In the newborn, a subcutaneous collection of fluid with poorly defined margins within the scalp, resulting from pressure on the head during delivery; soft-tissue swelling in a neonate’s head owing to fluid collection.

carboxyhemoglobin (COHb):

A measure of the amount of hemoglobin–carbon monoxide complexes in the blood.

cardiac imaging:

A broad array of modalities used to assess the cardiac system for structural disease, acute coronary syndrome, inflammatory conditions, and other conditions.

cardiac index (CI):

A hemodynamic value that adjusts a patient's cardiac output to take into account the total body surface area.

cardiac monitoring:

The continuous observation of the patient's condition in relation to the cardiac rhythm.

cardiac output (CO):

The amount of blood pumped out of the heart in 1 minute; the product of the stroke volume (average = 70 mL) and the heart rate (average = 60–100 beats/min).

cardiogenic shock:

A condition caused by loss of 40% or more of the functioning myocardium; the heart is no longer able to circulate sufficient blood to maintain adequate oxygen delivery. It may be caused by congenital cardiac defects, drug toxicity, metabolic causes, hypovolemia, myocarditis, and arrhythmias.

cardiomyopathy:

A general term for diseases in which the myocardium becomes thin, flabby, dilated, or enlarged, ultimately progressing to heart failure, acute myocardial infarction, or death.

carrier:

A person or animal that is infected with a disease, but does not express symptoms of that disease.

cathode:

The electrode in a pacing circuit that is negatively charged when current is flowing.

cation:

A positively charged ion.

cauda equina:

The collection of individual nerve roots into which the spinal cord separates at the L2 vertebra.

caudal:

Pertaining to or in the direction of the feet.

CBC with differential:

An expanded panel of lab tests that includes counts of specific types of white blood cells in the blood, such as neutrophils, lymphocytes, monocytes, eosinophils, and basophils.

central cord syndrome:

A syndrome in which cavities form in the central portions of the spinal cord, usually in the cervical area; it may be due to a tumor, a genetic mutation, or trauma. The syndrome presents along with hemorrhage or edema to the central cervical segments.

central cyanosis:

Blue coloration of the skin caused by the presence of deoxygenated hemoglobin in blood vessels near the skin surface.

central diabetes insipidus:

A condition caused by a decrease in ADH secretion from the posterior pituitary gland; characterized by polyuria and polydipsia, which lead to dehydration.

central line–associated bloodstream infection (CLABSI):

A primary bloodstream infection that develops in a patient who had a central line in place within the 48-hour period prior to the onset of the bloodstream infection.

central lumen:

The lumen or port of the intra-aortic balloon catheter used to guide initial catheter insertion and to monitor arterial pressure during operation.

central neurogenic hyperventilation:

A pattern of very deep, rapid respirations at rates of 40 to 60 breaths/min, caused by a midbrain lesion or dysfunction.

central venous lines:

Intravenous access catheters that terminate in the central circulation, usually just proximal to the right atrium.

central venous pressure (CVP):

The pressure in the superior vena cava (average = 2–6 cm H_2O), which reflects the pressure in the venous system when the blood is returned to the right atrium. It is indicative of a patient’s fluid volume status and right-side heart performance.

cephalad:

Pertaining to or in the direction of the head or front.

cephalohematoma:

A collection of blood between the bone and subperiosteal space; may be accompanied by a linear skull fracture.

cerebral angiography:

A procedure that uses imaging and a contrast material or dye to view and find abnormalities in the blood vessels in the brain.

cerebral aqueduct:

The narrowest portion of the brain’s ventricular system; it provides communication with the fourth ventricle, which lies between the brainstem and the cerebellum.

cerebral blood flow (CBF):

The amount of blood flow the brain requires to maintain homeostasis. In a 24-hour period, the brain requires 1,000 L of blood to obtain 71 L of oxygen and 100 g of glucose.

cerebral contusion:

A focal brain injury in which brain tissue is bruised and damaged in a defined area.

cerebral cortex:

The outermost layer of the cerebrum.

cerebral function analysis monitor (CFAM):

A device that can provide summed, averaged, and analyzed outputs of the general state of brain activity.

cerebral function monitor (CFM):

A device that can provide summed and averaged outputs, but not analysis, of the general state of brain activity.

cerebral hemispheres:

The name for each half of the brain (right or left); each of these areas contains one of the paired lobes (occipital, parietal, temporal, and frontal).

cerebral metabolic rate for oxygen ($CMRO_2$):

A measurement used to determine neuronal demand for oxygen. Neurons with high activity rates require greater amounts of oxygen.

cerebral perfusion pressure (CPP):

The pressure gradient across the brain; it provides an estimate of perfusion adequacy: CPP = MAP – ICP.

Charcot triad:

Fever, jaundice, and right upper quadrant abdominal pain suggestive of choledocholithiasis.

Charles's law:

A gas law stating that when pressure is constant, the volume of a gas is very nearly proportional to its absolute temperature. Thus, the volume is directly proportional to the temperature when it is expressed on an absolute scale where all other factors remain constant.

Cheyne-Stokes respiration:

A cyclic pattern of increased respiratory rate and depth with periods of apnea. Causes include increased intracranial pressure, renal failure, meningitis, drug overdose, or hypoxia secondary to congestive heart failure.

children with special health care needs (CSHCN):

As defined by the US Department of Health and Human Services, those children "who have or are at increased risk for a chronic physical, developmental, behavioral, or emotional condition and who also require health and related services of a type or amount beyond that required by children generally."

chloasma:

A dermatologic condition affecting pregnant women in which darkened skin patches appear on the cheeks and forehead.

choanal atresia:

A congenital narrowing or blockage of the nasal airway by membranous or bony tissue.

cholangitis:

A serious ascending infection due to biliary tract obstruction that can result in fever, transaminitis, and altered mental status.

cholecystitis:

Inflammation of the gallbladder.

choledocholithiasis:

Gallstones in the biliary tract system, which put the patient at high risk for developing a biliary tract obstruction; typically initially managed with endoscopic retrograde cholangiopancreatography rather than cholecystectomy.

cholelithiasis:

Gallstones in the gallbladder.

cholinergic syndrome:

Cholinesterase inhibitor toxicity.

chordae tendineae:

Tendons that connect the papillary muscles to the tricuspid and mitral valves.

choroid plexus:

A cluster of nerve roots at the lateral and the third and fourth ventricles of the brain that produce cerebrospinal fluid.

chronic kidney disease (CKD):

A gradual decrease in renal function resulting from irreversible damage to the nephrons. It is characterized by a glomerular filtration rate of less than 60 mL/min, and eventually progresses to end-stage renal disease.

chronotropic:

A medication that affects the rate of contraction of the heart; altering the heart rate.

circle of Willis:

A system of arteries located at the base of the skull that (in most people) is able to compensate for reduced blood flow from any one of the major contributors to cerebral circulation.

cirrhosis:

Irreversible structural changes to the liver that impair its proper functioning.

civil damages:

Monetary compensation awarded to a plaintiff in noncriminal court proceedings.

claudication:

A severe pain in a muscle caused by narrowing of the arteries in that muscle and leading to ischemic pain with slight exertion such as that associated with walking.

clubbing:

Broadening of a child’s fingers and toes in response to chronically low oxygen levels for longer than 3 months.

cluster breathing:

An abnormal respiratory pattern in which a cluster of irregular respirations that vary in depth are followed by a period of apnea at irregular intervals.

coarctation of the aorta:

The narrowing or constriction of part of the aorta or aortic arch of the heart.

cocaine washout syndrome:

Profound exhaustion with the ability to regain normal mental status and orientation when aroused; commonly seen with heavy cocaine users.

colitis:

Inflammation of the colon.

colonoscopy:

An endoscopy of the lower GI tract.

comminuted fracture:

A type of skull fracture in which the skull is splintered or shattered into many pieces.

Commission on Accreditation of Medical Transport Services (CAMTS):

An organization dedicated to improving the quality of patient care and safety of the transport environment for both rotor-wing and fixed-wing providers. CAMTS also provides voluntary accreditation of critical care transport agencies.

common law:

Case law established by prior disputes that is published to guide future proceedings.

community hospitals:

Community medical centers that offer emergency medicine and inpatient facilities but with limited inpatient specialists other than hospitalists and general surgery physicians.

compartment syndrome:

A condition that develops when edema and swelling result in increased pressure within soft tissues, causing circulation to be compromised, possibly resulting in tissue necrosis.

compensatory stage:

A stage of hypoxia in which the physiologic adjustments that occur in the respiratory and circulatory systems are adequate to prevent the effects of hypoxia. Factors such as environmental stress and prolonged exercise can potentiate certain effects of hypoxia.

competence:

A legal determination, through a statute or court proceeding, that a person is capable of making personal decisions, including about their health care.

complete breech:

A delivery presentation in which the buttocks present first and the legs are crossed inside the uterus.

complete spinal cord injury:

A complete disruption of all tracts of the spinal cord, with permanent loss of all cord-mediated functions below the level of transaction.

compliance:

A change in volume per unit of pressure; $\Delta V/\Delta P$.

computed tomography (CT):

An imaging modality in which x-rays are used in a 360° rotation around an object to generate a computed three-dimensional model that can be viewed as multiple slices through a given plane; also called computerized axial tomography (CAT) scan; provides a mathematically reconstructed view of multiple cross-sections of the body, including the brain; it should be performed on almost every patient with abnormal neurologic findings.

computed tomography angiography (CTA):

A form of imaging that includes the injection of an IV contrast agent into the patient moments before CT scanning and results in improved imaging of arterial structures.

concentration:

The amount of a substance present in a given volume of fluid.

concentration gradient:

The natural tendency for substances to flow from an area of higher concentration to an area of lower concentration, within or outside the cell.

concussion:

A transient interruption of normal neurologic function.

conduction:

Transfer of heat to a solid object or a liquid by direct contact.

congenital adrenal hyperplasia:

A group of diseases in which the adrenal glands do not function properly and as a result do not produce a sufficient amount of the hormone cortisol.

conjugate movement:

Movement of both eyes together in the same direction.

consent:

Voluntary agreement by a patient with sufficient mental capacity to capably accept or refuse assessment, treatment, or transport offered by the care provider.

contact phenomena injuries:

Injuries that occur as the direct result of trauma to the head, including local effects such as scalp laceration, skull fracture, hematoma, and intracerebral hemorrhage.

contamination:

A state in which a certain substance, such as blood, infectious material, or a toxic substance, is present on an item or surface. In the case of radiation, it is important to distinguish between contamination and irradiation.

continuous positive airway pressure (CPAP):

A means of raising the breathing baseline above the ambient pressure. The increased pressure across the entire breathing cycle increases the mean airway pressure, stents the airway, and increases the functional residual capacity, thereby improving oxygenation.

contrecoup injury:

A situation in which an impact occurs on one side of the head, causing the brain to move within the cranial vault and forcibly contact the opposite side of the skull, resulting in damage on that side of the brain; also called transitional injury.

controlled substances:

Drugs whose manufacture, possession, and use are controlled by the government.

convection:

The mechanism by which heat (body heat, in the context of this chapter) is picked up and carried away by moving air currents.

Coombs test:

A test used to identify antibodies that may bind to red blood cells and cause hemolysis.

corpus callosum:

A large tract of transverse fibers that provides a communication link between the two cerebral hemispheres.

covered entity:

As defined under HIPAA, a health care provider, a health plan, or a health clearinghouse that must transmit health information in electronic form in connection with a transaction covered by HIPAA (payment or administrative) to qualify. Ambulance providers of all kinds are explicitly included in the definition of a covered entity.

crackles:

A breath sound produced as fluid-filled alveoli pop open under increasing inspiratory pressure; can be fine or coarse.

cranial nerves (CN):

The 12 nerves arising directly from the brain that govern many of the senses and the functions of muscles in the eyes, face, and pharynx.

C-reactive protein (CRP):

An acute-phase reactant used to identify inflammatory response.

creatine:

A major storehouse of intramuscular high-energy phosphate.

creatine kinase (CK):

An enzyme that cleaves the high-energy phosphate from creatine in muscle tissues and transfers it to adenosine diphosphate to yield adenosine triphosphate; its measurement is used in the assessment for muscle damage.

creatinine (Cr):

A chemical waste product of creatine that results from muscle metabolism and is eliminated through the urine; increased levels indicate decreased GFR and renal function.

crew resource management (CRM):

A system that originated as the result of a National Aeronautics and Space Administration workshop in 1979 as a means to improve air safety. It incorporates equipment, procedures, and crew concerns to make the best decision during flight operations, focusing on interpersonal communication, leadership, and decision making.

critical-access hospitals:

As defined by the Centers for Medicare and Medicaid Services, hospitals that have 25 or fewer beds, are located more than 35 miles from another hospital, have an average length of stay of less than 96 hours, and provide 24/7 emergency medicine services. Most acutely ill or injured patients treated at these hospitals require transport to higher levels of care once stabilized.

critical care:

Constant, complex, detailed health care as provided in various acute life-threatening conditions; the ability to deal with such situations rapidly and with precision using various advanced machines and devices for treating and monitoring the patient’s condition.

critical care patient:

Any patient who experiences an actual or potential life-threatening illness or injury that requires continual monitoring and care by a specially trained physician, registered nurse, or paramedic.

critical care transport (CCT):

The transport of a patient from an emergency department, critical care unit, or incident scene during which the patient receives the same level of care as was provided in the hospital or originating facility.

critical care transport professional (CCTP):

A health care professional who has successfully completed a recognized critical care program and meets the minimum qualifications set forth by the employing transport program.

critical incident stress debriefing (CISD):

An approach favored since the 1980s to manage the psychological aftereffects in emergency personnel after particularly distressing responses; it requires a specially trained team and has the potential to create iatrogenic harm.

critical stage:

The stage of acute hypoxia in which there is almost complete mental and physical incapacitation, resulting in rapid loss of consciousness, seizures, respiratory arrest, and death.

Crohn disease:

An inflammation of the GI tract in which all layers of the mucosa may be affected. It results in scattered ulcerations and fibroses throughout the large and small intestines.

cross-tolerance:

A form of drug tolerance in which patients who take a particular medication for an extended period can build up a tolerance to other medications in the same class.

croup:

A childhood viral disease characterized by edema of the upper airways with barking cough, difficult breathing, and stridor; also called laryngotracheobronchitis.

crush syndrome:

The combination of shock and renal failure after a crush injury; it may lead to the death of an entrapped person after the patient is freed from the entrapment.

cryoprecipitate:

A blood product created from plasma and in which clotting factors, especially factor VIII, are concentrated; it is used to treat patients with coagulation disorders.

CT angiography:

Radiographic observation of dye injected into the bloodstream.

CT polytrauma:

An imaging protocol that typically includes computed tomography (CT) of the head, cervical spine, chest, and abdomen/pelvis to generate a continuous image from the top of the head through the pelvis; also called a pan-scan.

cumulative effect:

An effect that occurs when several successive doses of a medication are administered or when absorption of a medication occurs faster than its excretion or metabolism.

current:

The movement of electrons through an electrical circuit over time, measured in amperes.

Cushing syndrome:

A condition caused by overproduction of cortisol by the adrenal glands or by excessive use of cortisol or other similar steroid (glucocorticoid) hormones; also known as hypercortisolism.

Cushing triad:

A cascade of events provoked when intracranial pressure rises to the level of the arterial pressure, vasoconstriction occurs in an effort to shift fluid volumes in the cranium, and the ensuing brain displacement puts pressure on the medulla oblongata by pushing it into the foramen magnum, resulting in disturbances in breathing, heart rate, and blood pressure.

cyanosis:

Blue discoloration of the gums and face.

cyanotic congenital heart disease (CCHD):

Heart disease caused by developmental anomalies of the heart or major vessels (truncus arteriosus, transposition of the great vessels, tetralogy of Fallot, tricuspid atresia, or total anomalous pulmonary venous return) leading to abnormal blood flow. Deoxygenated blood from the right side of the heart is shunted to the left side, causing cyanosis.

cyanotic defects:

Congenital heart defects that lead to low oxygen saturation, owing to either decreased pulmonary blood flow or mixed blood flow.

cytokines:

Chemical messengers that enhance cell growth, promote cell activation, direct cellular traffic, stimulate macrophage function, and destroy antigens. Interleukins are a type of cytokine.

Dalton’s law:

A gas law stating that the total pressure of a gas mixture is the sum of the individual or partial pressures of the gases in the mixture; also referred to as the law of partial pressure.

damages:

In a legal context, harm that results from a breach of duty by a health care provider who is found negligent. Usually, the injury is physical.

dampened waveform:

A hemodynamic pressure waveform that appears to have lost crisp deflections.

D-dimer test:

A test of hypercoagulability that detects a fragment from the fibrinolysis process; the test can be used to help diagnose and monitor diseases and conditions related to inappropriate clotting, such as deep venous thrombosis.

debriefing:

A powerful inquiry tool in which a concise exchange occurs to identify what happened, what was learned, and what can be done better in the future.

decision-making capacity (DMC):

The determination that a patient’s brain is functioning well enough to process information and make health care decisions.

decompression sickness:

A condition resulting from exposure to low barometric pressure, causing inert gases normally dissolved in body fluids and tissue to come out of physical solution and form bubbles.

decontamination:

Use of chemical, physical, or other means to remove, inactivate, or eradicate harmful microorganisms from people, surfaces, or objects.

deep partial-thickness burn:

A burn in which the skin is blistered but not charred and is painful to the touch; it is usually the result of steam, oil, or flames and involves the deeper layers of the dermis.

delayed hemolytic transfusion reactions:

Transfusion reactions that do not occur until 3 to 30 days after transfusion.

delayed traumatic intracranial hemorrhage (DTICH):

Hemorrhage that occurs within the first 3 to 10 days following an injury to the occipital-parietal region via a coup–contrecoup mechanism.

delirium:

Acute confusion, hallucinations, and disorientation that is rapid in onset and may fluctuate in intensity.

delta wave:

The slurring of the upstroke of the first part of the QRS complex that occurs in Wolff-Parkinson-White syndrome.

depolarization:

The process of discharging resting cardiac muscle fibers by an electrical impulse that causes them to contract.

depolarizing paralytic:

A medication that causes neuromuscular blockade by binding and briefly activating receptor sites at the neuromuscular junction, preventing further activation of these sites and causing chemical paralysis.

depressed skull fracture:

A type of skull fracture in which a portion of the skull is depressed; the scalp and dura may or may not be torn.

dermis:

The layer of skin that lies beneath the epidermis; it is a dynamic layer of thick connective tissue.

destination therapy (DT):

A treatment objective in which a left ventricular assist device is implanted in a patient with heart failure as ongoing mechanical circulatory support because the patient does not meet the heart transplantation criteria.

dextrocardia:

A congenital cause of right axis deviation, in which the heart develops in a right-facing position, creating a mirror image of the normal left-facing heart.

diabetes mellitus:

A metabolic disorder in which the pancreas's ability to metabolize simple carbohydrates (glucose) is impaired because of either inadequate production of insulin or insensitivity to circulating insulin.

diabetic ketoacidosis (DKA):

A form of acidosis observed in uncontrolled diabetes in which ketones accumulate when insulin is not available; usually associated with hyperglycemia.

diagnostic peritoneal lavage (DPL):

A surgical procedure to assess for bleeding or intestinal perforation in the abdomen. Classically, a liter of crystalloid is infused into the abdomen and then drawn out to examine for the presence of blood or intestinal contents.

diaphragma sellae:

An extension of the dura mater that forms a roof over the sella turcica, which contains the pituitary gland.

diaphragmatic hernia:

Passage of loops of bowel, with or without other abdominal organs, through the diaphragm muscle; it occurs as the bowel from the abdomen herniates upward through the diaphragm into the chest (thoracic) cavity.

diastatic stellate fracture:

A fracture involving injury to a bone with separation of an epiphysis; it is prevalent in abused children.

diastole:

The relaxation phase of the heart cycle, in which the ventricles are dilated and filling with blood.

diastolic augmentation:

The increase in aortic pressure during diastole that the intra-aortic balloon inflation produces, thereby improving coronary and peripheral perfusion; it may be thought of as a “second systole.”

diastolic blood pressure (DBP):

The trough or resting pressure in the arterial system that occurs during ventricular diastole.

dicrotic notch:

The brief increase in aortic pressure reflected in a notching of the wave; it is caused by the sudden closure and springing back of the aortic valve leaflets, and signals the start of diastole.

diencephalon:

Portion of the cerebrum consisting of the thalamus, the hypothalamus, the subthalamus, and the epithalamus.

differential diagnosis:

The process of selecting the most likely underlying cause of the patient’s condition by comparing multiple potential causes of the presenting signs and symptoms.

difficult airway:

An airway in which the provider anticipates complications in securing an airway.

diffuse axonal injury (DAI):

A deep-brain injury in which shearing forces damage the integrity of the axon at the node of Ranvier, which consequently alters the axoplasmic flow.

digoxin:

A cardiac glycoside that produces positive inotropic and negative chronotropic activity in the heart and is primarily indicated in the treatment of chronic heart failure and to control the ventricular rate in atrial tachyarrhythmias.

dilation and curettage (D&C):

A surgical procedure in which the cervix is opened and the uterus scraped of tissue.

dilutional hyponatremia:

A condition caused by excessive intake of fluids in which serum sodium concentration is less than 135 mmol/L; sometimes referred to as water intoxication.

diplopia:

Double vision.

direct bilirubin:

Conjugated bilirubin; the result of bilirubin’s conjugation in the liver, which is ultimately excreted in the bile.

discordant:

A descriptor for T waves that are in the opposite direction from the terminal portion of the QRS complex in bundle branch blocks.

discovery rule:

A legal rule stating that the statute of limitations for filing a legal case does not begin until the injured party can reasonably be expected to know of the injury.

dispatch:

The person or organization that receives the request for critical care transport and contacts the critical care transport team with the details of that request to ascertain the team’s availability.

disseminated intravascular coagulation (DIC):

A complex condition arising from different causes that activate coagulation mechanisms, resulting in obstructed blood flow as a result of microclots as well as fibrinolysis, while the body attempts to reopen the microcirculation. Bleeding, thrombosis, and, potentially, organ dysfunction result.

distal intestinal obstruction:

Partial or complete obstruction of the distal small bowel (ileum) or large intestine.

distribution:

The process by which molecules move from the body’s systemic circulation to specific organs and tissues.

distributive shock:

A form of shock in which the smallest blood vessels fail to deliver adequate blood to the tissues; it includes neurogenic shock, anaphylactic shock, and septic shock.

disturbance stage:

A stage of hypoxia in which physiologic responses are inadequate to compensate for the oxygen deficiency, and hypoxia is evident.

diverticula:

Small pouches of tissue that develop as outcroppings of the large intestine, typically in the descending colon and sigmoid colon.

diverticular bleeding:

Bleeding from diverticula that have developed in the colon.

diverticulitis:

Inflammation of diverticula.

diverticulosis:

Presence of intestinal diverticula, which may then become inflamed or bleed.

doll's eye test:

An oculocephalic reflex test that is performed on the unconscious patient by rapidly rotating the head from side to side and observing the eye movement.

do not resuscitate (DNR) order:

A type of advance directive that describes which life-sustaining procedures should be performed if the patient suffers cardiopulmonary arrest.

dopamine:

A neurotransmitter that plays important roles in executive function, impulsivity, sensory perception, and key physiologic parameters (eg, heart rate, blood pressure, temperature regulation).

dorsal:

Toward the back surface of an object; posterior.

drag:

The resistance of an aircraft to forward motion, directly opposed to thrust.

dromotropic:

Influencing the conduction rate within the heart; affecting the velocity of conduction.

drug interaction:

The alteration of the action or metabolism of a particular medication when combined with another medication.

dual-chamber pacemaker:

An artificial pacemaker with two leads (one in the atrium and one in the ventricle) so electromechanical synchrony can be achieved.

DUMBELS:

Mnemonic for symptoms of anticholinesterase inhibitor toxicity: Diaphoresis/diarrhea, Urination, Miosis, Bradycardia/bronchospasm/bronchorrhea, Emesis, Lacrimation, and Salivation.

dural venous sinuses:

Endothelial-lined spaces between the periosteal and meningeal layers of the dura mater.

dura mater:

The outer membrane of the meninges.

duration of action:

The amount of time a medication concentration can be expected to remain above the minimum level needed to provide the intended action.

duty to act:

A legal obligation of health care providers to render medical care to a certain level. When the duty to act applies varies from state to state.

dysarthria:

Difficulty articulating words caused by neurologic impairment affecting the vocal apparatus.

dysbarism:

A condition resulting from the effects (excluding hypoxia) of a pressure differential between the ambient barometric pressure and the pressure of gases within the body.

dysconjugate movement:

Lack of symmetric movement between the two visual axes.

dyscrasia:

In hematology, a disorder of the cellular elements of blood.

dysphonia:

Difficulty producing intelligible speech caused by physical impairment at the level of the larynx.

early pregnancy loss:

Expulsion of the fetus that occurs naturally; also called miscarriage or spontaneous abortion.

eclampsia:

The condition that exists once a patient with preeclampsia develops seizures; it causes serious maternal complications. Warning signs of the transition from preeclampsia to eclampsia include severe headache, scotomata, hyperreflexia, epigastric pain, and anxiety.

ectopic pregnancy:

A pregnancy in which the ovum implants somewhere other than the uterine endometrium.

Edinger-Westphal nucleus:

Part of the midbrain that is responsible for mediating the autonomic reflex centers for pupillary accommodation to light.

effective performance time:

The amount of time an individual is able to perform useful duties in an environment of inadequate oxygen; also known as expected performance time.

efferent pathways:

Descending pathways that carry motor impulses away from the central nervous system.

ejection fraction:

The average percentage of blood ejected from the left ventricle with each heartbeat.

elastance:

The tendency to collapse (as in lung tissue).

electrical alternans:

An electrocardiogram pattern in which the QRS vector changes with each heartbeat. This pattern is pathognomonic of cardiac tamponade.

electrode:

In the context of a 12-lead electrocardiogram, an electrical sensor placed on the chest to record the bioelectrical activity of the heart. In the context of a pacemaker, a conductor in contact with cardiac tissue at the end of a pacing lead; it delivers impulses to that tissue.

electroencephalography (EEG):

A procedure that records the electrical activity of the brain by measuring brain waves.

electrophysiology:

The cardiac specialty that involves evaluation and management of rhythm disturbances.

embolic stroke:

A condition in which a blood clot, known as an embolus, forms in one part of the body and travels through the bloodstream to the brain or neck.

emergency medical condition:

A condition manifesting itself by acute symptoms of sufficient severity (including severe pain) such that the absence of immediate medical attention could reasonably be expected to result in placing the individual’s health (or the health of an unborn child) in serious jeopardy, serious impairment to bodily functions, or serious dysfunction of bodily organs.

Emergency Medical Treatment and Active Labor Act (EMTALA):

A federal law passed by the US Congress in 1986, with the primary goal of preventing hospitals from failing to treat patients, or transferring patients to other facilities, based on their insurance status or ability to pay for services.

empyema:

An accumulation of pus in the pleural space.

endemic:

A pattern of disease occurrence in which some cases of a disease are always present within a given population, and their numbers are expected and predictable.

endocardial (transvenous) leads:

Pacemaker leads guided by angiography and attached to the endocardium.

endocrine hypertension:

Significant high blood pressure caused by a hormonal disorder; often related to excess hormone produced by a tumor.

endometrium:

The inner mucous membrane of the uterus.

endoscopic retrograde cholangiopancreatography (ERCP):

A technique combining endoscopy and fluoroscopy to diagnose and treat biliary or pancreatic ductal obstruction.

endotoxins:

Lipopolysaccharides that coat the outer surface of gram-negative bacteria and elicit strong immune responses in humans while providing a layer of protection for the bacterium; they can also be secreted from the cell and are released en masse when cell death occurs.

end-stage renal disease (ESRD):

A loss of proper kidney functioning, with renal replacement therapy becoming a requirement for survival.

enhanced elimination:

A process that replaces or augments the body’s normal method of eliminating, modifying, or breaking down toxic substances.

enteroclysis:

Infusion of barium contrast into the GI tract to observe for obstruction.

enzymes:

Proteins that act as catalysts for biochemical reactions within the body.

epicardial leads:

Pacemaker leads attached to the epicardium (outer surface of the myocardium); placement and troubleshooting of these leads are done in the hospital and require surgery and anesthesia.

epidemic:

A pattern of disease occurrence in which the number of cases of a disease clearly rises (above a threshold level) in a given time or geographic area.

epidemiology:

The study of disease distribution within populations and the factors that determine that distribution.

epidermis:

The outer layer of the skin, which generally consists of four layers (thin skin), except on the palms, fingertips, and soles of the feet, which have five layers (thick skin).

epidural hematoma (EDH):

An accumulation of blood between the inner periosteum and the dura mater; also called extradural hematoma.

epiglottitis:

Inflammation of the epiglottis.

epithalamus:

An area of the cerebrum that is located in the dorsal portion of the diencephalon and contains the pineal gland.

epitope:

The specific portion of the antigen that is recognized by the antibody or B cell.

error:

A preventable adverse event in the delivery of care, whether or not it is evident or harmful to the patient.

erythrocyte sedimentation rate (ESR):

The rate at which red blood cells settle at the bottom of a tube containing a blood sample. This test is used to identify inflammatory response and is generally less specific than testing C-reactive protein.

eschar:

The leathery covering of a burn injury, formed after the burned tissues dry out.

escharotomy:

A surgical incision in an eschar to lessen constriction; sometimes necessary (although rarely performed in a prehospital setting) to prevent edema from building up, impairing capillary filling and causing ischemia.

esophageal atresia:

A congenital defect, often associated with other anomalies such as tracheoesophageal fistula, in which the esophagus ends in a blind pouch.

esophageal varix:

Swelling of esophageal veins that intrudes into the lumen of the esophagus.

esophagitis:

Inflammation of the tissues of the esophagus; commonly associated with severe gastroesophageal reflux disease, alcohol abuse, or irritation caused by pills or infection.

esophagogastroduodenoscopy (EGD):

A technique to directly observe the GI tract in which a camera is passed into the GI tract, allowing for diagnosis and treatment of disease or injury.

etiology:

The cause of a disease.

eupnea:

Normal breathing at a rate of 12 to 20 breaths/min in the adult patient.

evaporation:

The conversion of a liquid to a gas.

excited delirium:

A complex, life-threatening syndrome including both delirium and an excited or agitated state; also called agitated delirium.

exercise-associated hyponatremia (EAH):

A condition occurring within 24 hours of sustained physical activity in which fluid consumption exceeds fluids lost, resulting in dilution of serum sodium levels. Signs and symptoms may include nausea, vomiting, and, in severe cases, mental status changes and seizures.

exertional heatstroke:

A thermoregulatory emergency that occurs during activities that require physical exertion in warm environments. This condition is defined by an excessive core body temperature, typically greater than 104°F (40°C), and associated CNS impairment.

exhalation:

A passive process in which gas leaves the lungs.

exotoxins:

Proteins that are secreted by some bacteria and can directly cause significant damage to host cells while also triggering an immune response.

expiratory reserve volume (ERV):

The amount of air that can be expelled from the lungs after a normal exhalation.

exploratory laparotomy:

Surgical exploration of the abdomen.

expressed consent:

A patient’s voluntary verbal, nonverbal, or written agreement to consent to treatment or transport.

external fetal monitoring:

Electronic heart monitoring of the fetus while in utero, performed via electrodes placed on the pregnant woman’s abdomen.

extinction:

A test of sensation discrimination in which the CCTP simultaneously touches opposite, corresponding areas of the patient’s body and asks the patient where the touch is felt; it is intended to identify sensory inattention.

extracorporeal membrane oxygenation (ECMO):

A temporizing mechanism of extracorporeal gas exchange with or without hemodynamic support; also referred to as extracorporeal life support.

extradural space:

A potential space between the cranial bones and the periosteal layer of the dura that becomes a real space only when blood from torn vessels pushes the periosteum from the cranium and accumulates; also called epidural space.

extravasation:

An infusion-related complication in which the drug being administered intravenously leaks outside the vein and enters the surrounding tissues; if that substance is a vesicant, it can cause blisters and tissue damage.

face-to-face intubation:

Intubation in which the provider’s face is at the same level as the patient’s face; used when the standard position is not possible. In this position, the laryngoscope is held in the provider’s right hand and the endotracheal tube in the left.

failed airway:

An unsuccessful intubation attempt in a patient for whom oxygenation cannot be adequately maintained with bag-mask ventilation; three unsuccessful intubation attempts by an experienced operator but with adequate oxygenation; and failed intubation using one best attempt in the “forced to act” situation.

failure mode and effect analysis (FMEA):

A process that helps identify priorities in risk mitigation and process redesign.

falx cerebelli:

A fold of dura mater that forms the division between the two lateral lobes of the cerebellum.

falx cerebri:

A double fold of dura mater that divides the cerebrum into right and left hemispheres by descending vertically into the longitudinal fissure that extends from the frontal lobe to the occipital lobe.

fasciotomy:

A surgical incision into an area of fascia—for example, to relieve pressure between two compartments; not usually performed in a prehospital setting.

fat-free mass (FFM):

The proportion of body mass that consists of tissues other than adipose tissue, and that therefore consumes calories; typically the largest determinant of the basal metabolic rate in a healthy person.

fecal-oral route:

A route of transmitting infectious organisms from one individual to another; commonly, enteric bacteria or viruses are shed in the feces, spread via contamination of food or water sources, and ingested by other people.

Federal Aviation Administration (FAA):

A US governmental agency within the Department of Transportation that regulates and oversees civil aviation within the United States; it established and enforces the Title 14 CFR that govern aircraft operation within the United States.

Fick principle:

A method of indirectly determining cardiac output, in which the amount of oxygen uptake of blood as it passes through the lungs is equal to the oxygen concentration difference between mixed venous and arterial blood. The formula uses assumed values for oxygen consumption derived from basal metabolic studies on healthy subjects, which may or may not be valid in critically ill patients.

Fick’s law:

A gas law stating that the net diffusion rate of a gas across a fluid membrane is proportional to the difference in partial pressure, proportional to the area of the membrane, and inversely proportional to the thickness of the membrane.

first-order elimination:

The rate of elimination is proportional to the drug’s plasma concentration.

first-pass effect:

A process by which the dose of an oral medication is reduced as it passes through the liver (and, for some medications, the gut as well as the liver) before it enters systemic circulation; also called first-pass metabolism.

fissures:

Deep grooves between adjacent gyri of the brain.

fixed-wing aircraft:

A transportation mode typically used to transport critically ill and injured patients distances of 150 miles (240 km) or greater; also called airplanes.

FLACC scale:

A pain assessment scale that scores points for five categories, including face, legs, activity, cry, and consolability.

flail chest:

A fracture in two or more places to two or more adjacent ribs.

flat fracture:

The least common type of depressed skull fracture, in which the depressed segment does not have any connection with the cranial vault.

flexion-extension injury:

A spinal cord injury that results from forward movement of the head, typically as the result of rapid deceleration, or from a direct blow to the occiput.

flicker vertigo:

An imbalance in brain cell activity caused by exposure to low-frequency flickering or flashing light. Light flickering from 4 to 20 times per second can precipitate reactions including nausea, migraines, unconsciousness, and seizures.

flight following:

A service in which an authorized air-traffic control facility maintains constant contact with aircraft to notify the crew about traffic in the area.

flight surgeon:

A physician who specializes in flight medicine and has been trained extensively in various aspects of aviation and the effects of flight on the human body; also specializes in working with pilots and flight crew members.

flow-cycled ventilator:

A positive-pressure ventilator that ends inspiration when a predetermined flow rate is achieved.

flow rate:

The speed of the gas at which the tidal volume is delivered.

focal ischemic stroke:

A condition in which an area of marginally perfused tissue, the ischemic penumbra, surrounds a core of ischemic cells; the cells will eventually die without medical intervention.

focused assessment with sonography for trauma (FAST):

An ultrasonographic examination directed at identifying the presence of free intraperitoneal or pericardial fluids, performed by transducing four distinct areas of the abdomen.

fomite:

An inanimate object that is capable of transmitting infectious organisms from one individual to another.

footling breech:

A delivery presentation in which both feet extend into the birth canal.

foramen magnum:

The opening at the base of the skull through which the bundle of nerve fibers constituting the spinal cord exits.

foramen of Luschka:

An opening at the lateral portion of the base of the fourth ventricle that leads to the subarachnoid space and is essential for the normal flow of cerebrospinal fluid; part of the brain’s ventricular system.

foramen of Magendie:

An opening at the medial portion of the base of the fourth ventricle that leads to the subarachnoid space and is essential for the normal flow of cerebrospinal fluid; part of the brain’s ventricular system.

foramen of Monro:

An opening in the skull that connects the two lateral ventricles with the third ventricle, a central cavity; part of the brain’s ventricular system.

foramen ovale:

The opening in the fetal heart that allows blood to flow from the right atrium to the left atrium of the fetus, bypassing the lungs prior to birth.

Foster Kennedy syndrome:

A tumor or abscess at the base of the frontal lobe that affects the olfactory nerve.

fraction of inspired oxygen (FIO_2):

Percentage of inhaled oxygen expressed as a decimal. For example, 40% oxygen = F_{IO_2} of 0.40.

fracture:

A break in the continuity of a bone.

frank breech:

A delivery presentation in which the buttocks present first, both of the infant's hips are flexed, and the feet are near the fetus's head.

Frank–Starling law:

The principle that the force of the cardiac muscle contraction is proportional to the amount of stretch placed on the muscle fibers (meaning that the more the heart is stretched by the incoming blood, the more forcefully the ventricles contract and the more blood that is ejected); it demonstrates how changes in ventricular preload lead to changes in stroke volume; also called the Starling curve.

free water:

Water that is not bound to molecules in the body.

fresh-frozen plasma (FFP):

A blood product in which uncoagulated plasma has been separated from the red blood cells; it is primarily composed of water, proteins, salts, metabolites, and clotting factors.

frontal lobe:

The largest of the four lobes of the brain; it lies underneath the frontal bone of the skull and is separated posteriorly from the parietal lobe by the central fissure and inferiorly from the temporal lobe by the lateral fissure. The frontal lobe is responsible for a variety of cognitive and motor functions.

frostbite:

Localized damage to tissues resulting from prolonged exposure to extreme cold.

full-thickness burn:

A burn that extends through the epidermis and dermis into the subcutaneous tissues beneath, in which skin is pale, painless, leathery, and charred; also called a third-degree burn.

fulminant hepatic failure:

A sudden and significant insult to the liver characterized by encephalopathy and a high mortality rate; commonly caused by toxins/overdose or viral infection.

functional residual capacity (FRC):

The amount of air remaining in the lungs after normal expiration; the sum of the residual volume and the expiratory reserve volume.

functioning adenoma:

A type of pituitary lesion in which overproduction of hormones occurs.

fundus:

The optic disk, macula, and blood vessels on the back wall of the internal eyeball.

gallstone pancreatitis:

A type of pancreatitis in which pancreatic enzymes accumulate proximal to a bile duct obstruction from a gallstone and digest the tissues of both the duct and the pancreas.

gas lumen:

The lumen or port of the intra-aortic balloon catheter that carries helium between the intra-aortic balloon and the pump console to inflate and deflate the balloon.

gastritis:

Inflammation of the gastric mucosa that occurs when the equilibrium of active and protective mechanisms for the lining is altered; may be accompanied by upper GI bleeding.

gastroenteritis:

Watery diarrhea and vomiting during inflammation of the digestive tract as a result of a viral, bacterial, or parasitic infection.

gastroschisis:

A centrally located, full-thickness abdominal wall defect.

Gay-Lussac's law:

A gas law stating that the pressure of a gas when volume is maintained at a constant level is directly proportional to the absolute temperature for a constant amount of gas. Simply stated, as pressure increases, temperature increases.

gestation:

Period of time from conception to birth. For humans, the full period is normally 9 months (or 40 weeks).

gestational diabetes:

A condition in which a woman without previous diabetes develops high blood glucose, especially during the third trimester.

gestational hypertension:

The occurrence of hypertension in a pregnant woman, usually after 20 weeks' gestation, defined as a blood pressure of 140/90 mm Hg or greater in a woman with a previously normal blood pressure; also called pregnancy-induced hypertension.

gigantism:

A syndrome that results from excessive secretion of growth hormone by the pituitary gland before the epiphyseal plate has closed; characterized by the growth of bones, muscles, and many internal organs at an abnormally fast rate.

Glasgow Coma Scale (GCS):

An evaluation tool used to determine level of consciousness, which evaluates and assigns point values (scores) for eye opening, verbal response, and motor response, which are then totaled; effective in helping predict patient outcomes.

global ischemic stroke:

A condition in which severe hypotension or cardiac arrest produces a transient drop in blood flow to all areas of the brain.

glomerular filtration rate (GFR):

The amount of fluid filtered by the glomerulus per minute; a benchmark for renal function.

gluconeogenesis:

Glucose formation.

glycogenolysis:

The breakdown of glycogen to glucose.

glycosuria:

The presence of glucose in the urine.

Graham’s law:

A gas law stating that the rate at which gases diffuse is related inversely to the square root of their densities.

gravitational forces:

Force changes that occur with acceleration and deceleration.

gyri:

Convolutions on the surface of the cerebrum that functionally increase the cortical surface area.

half-life (T½):

The time period required to eliminate one-half of the plasma concentration. During the second half-life, an additional 25% of the original plasma concentration is eliminated. After three half-lives, one-eighth of the original plasma concentration remains.

halo test:

A test for leaking CSF that is accomplished by collecting and assessing fluid that drains from the nose, mouth, or ears; a dark red circle of fluid surrounded by a lighter yellow one is a positive halo sign.

handoff:

The brief report that staff at the sending facility—generally the bedside nurse, physician, or care provider currently responsible for the patient—submits to the CCTP team when they arrive to accept responsibility for the patient's care.

harm:

Unintended physical injury resulting from or contributed to by medical care.

Hashimoto disease:

A condition that occurs when the immune system attacks the patient's thyroid gland and that is the leading cause of hypothyroidism; also known as chronic lymphocytic thyroiditis.

health care–associated pneumonia (HCAP):

Pneumonia that occurs in nonhospitalized patients who have contact with health care facilities or personnel.

Health Insurance Portability and Accountability Act (HIPAA):

A federal law enacted in 1996, providing for criminal sanctions and civil penalties for releasing a patient's protected health information in a way not authorized by the patient.

heart failure (HF):

A set of clinical signs and symptoms indicative of myocardial dysfunction and cardiac output that is inadequate to meet the metabolic demands of the body.

heat cramps:

Acute and involuntary muscle pains, usually in the lower extremities, the abdomen, or both, that occur because of profuse sweating and subsequent sodium loss in sweat.

heat exhaustion:

A clinical syndrome characterized by volume depletion and heat stress that is thought to be a milder form of heat illness on the continuum leading to heatstroke.

heatstroke:

The least common and most deadly heat illness, caused by a severe disturbance in thermoregulation, usually characterized by a core body temperature of more than 104°F (40°C) and altered mental status.

heat syncope:

An orthostatic or near-syncopal episode that typically occurs in nonacclimated people who may be under heat stress.

***Helicobacter pylori*:**

A bacterium that is commonly associated with gastritis and peptic ulcers.

helicopter emergency medical service (HEMS):

Use of a rotor-wing aircraft to deliver air medical service, for which the goals are to rapidly transport CCTPs to a patient, stabilize the patient’s condition, and rapidly transport that patient to a tertiary care center.

helicopter shopping:

The practice of making sequential calls to numerous air medical providers in an attempt to find a service that will accept a mission request that has been declined by other services based on safety factors such as poor weather, limited landing zone availability, exceptional distances, or other factors.

HELLP syndrome:

A hemolytic disorder that occurs during the latter stages of gestation, usually after the 20th week, and whose clinical findings include hemolytic anemia, elevated liver enzyme levels, and a low platelet count. Patients will present with blurred vision, abdominal pain, headache, and edema.

hematemesis:

Emesis containing blood, which may be bright red or partially digested (coffee-ground emesis).

hematochezia:

Stool streaked with bright red blood.

hematocrit:

The percentage of formed elements (cells) in a venous blood sample.

hematuria:

The presence of red blood cells in the urine.

hemiblock:

Blocking of one of the fascicles of the left bundle branch, the left anterior or left posterior fascicle.

hemoconcentration:

Decreased fluid in the blood, which means that concentrations of other blood components increase.

hemoglobin:

The protein responsible for carrying oxygen to the body’s cells and, to a lesser extent, carbon dioxide back to the lungs.

hemoglobinuria:

The presence of hemoglobin in the urine.

hemolysis:

Destruction of red blood cells, sometimes following massive blood transfusions or blood transfusion reactions; results in the release of hemoglobin and cell remnants into the bloodstream.

hemolytic transfusion reactions:

Transfusion reactions caused by ABO or Rh incompatibility, intradonor incompatibility, improper crossmatching, or improper blood storage.

hemolytic uremic syndrome (HUS):

A serious condition in which the patient develops acute kidney injury, and which also causes anemia and thrombocytopenia; thought to be caused by several bacterial and viral infectious organisms, most often verotoxin-producing strains of *Escherichia coli*.

hemoperfusion:

A treatment in which a patient’s blood is filtered outside the body through a substance that removes toxic substances from it; a method of removing toxic substances from the blood.

hemophilia:

A disease caused by inheritance of a recessive gene trait that causes excessive bleeding. The resulting factor VIII or factor IX deficiency leaves the blood unable to clot properly.

hemorrhagic conversion:

The condition in which, after the brain tissue surrounding the stroke has died, renewed blood flow to the region (eg, triggered by medication) is no longer held in place by the tissue, resulting in hemorrhage.

hemorrhagic stroke:

A condition in which bleeding in the intraparenchymal space or subarachnoid space causes direct or secondary damage to cerebral tissue.

hemothorax:

An accumulation of blood in the pleural space.

Henry's law:

A gas law stating that the amount of gas dissolved in solution is directly proportional to the pressure of the gas over the solution.

hepatic encephalopathy:

Encephalopathy secondary to hepatic disease, usually associated with hyperammonemia.

hepatitis:

Inflammation of liver cells that can impede proper functioning of the liver and lead to chronic conditions such as cirrhosis.

hepatitis C virus:

The virus that is the most common cause of cirrhosis and is especially pathogenic in causing hepatitis.

hepatorenal syndrome:

A condition characterized by renal injury and renal failure in patients with cirrhosis; decreased cardiac output and decreased systemic vascular resistance result in a cycle of worsening renal perfusion and renal vasoconstriction.

hepatotoxicity:

Damage to the liver.

hernia:

A protrusion of an organ from its tissue lining.

hexaxial system:

The system developed to describe the coronal plane that is created by the limb leads (I, II, III, aVR, aVL, and aVF).

high-altitude cerebral edema (HACE):

An altitude illness characterized by a change in mental status and/or ataxia in a person with acute mountain sickness, or the presence of mental status changes and ataxia in a person without acute mountain sickness.

high-altitude pulmonary edema (HAPE):

An altitude illness characterized by dyspnea at rest, cough, severe weakness, and drowsiness that may eventually lead to central cyanosis, audible rales or wheezing, tachypnea, and tachycardia.

high-flow nasal cannula (HFNC) therapy:

A form of noninvasive ventilation used to treat hypoxic respiratory failure by delivering up to 100% humidified and heated oxygen at a flow rate of up to 60 L/min.

high-level disinfection:

Treatment used on inanimate objects that kills all microorganisms, but does *not* kill bacterial spores.

highly reliable organization (HRO):

An organization that focuses on managing its inevitable failures, so that a failure does not affect the patient or the customer.

hippus phenomenon:

A pattern of pupil response to light in which rapid constriction of the pupil is followed by dilation; it can be normal or signify compression of cranial nerve III.

Hirschsprung disease:

A congenital lack of ganglion nerve cells in a portion of the distal intestines leading to poor intestinal peristalsis, constipation, and, if not diagnosed and treated, potentially death.

histamine:

A neurotransmitter that is released by cells in response to injury and in allergic and inflammatory reactions; it causes vasodilation and contraction of smooth muscle tissue.

histotoxic hypoxia:

Hypoxia caused by the inability of the tissues to use oxygen, usually as a result of poisoning by toxins such as carbon monoxide and cyanide.

homeostasis:

Stability in the body's internal environment.

hospital-acquired pneumonia (HAP):

Pneumonia that occurs in a hospitalized patient 48 hours or more after admission to the hospital, but that was not apparent at the time of admission.

huddle:

A communication technique and event that often takes the form of a structured, short meeting in which patient care teams come together to talk about a patient, procedure, or situation.

human leukocyte antigen (HLA):

An antigen present on the cell membrane surfaces of circulating platelets, white blood cells, and most tissue cells.

humidity:

The degree of moisture in the air, expressed as a percentage.

hydrocephalus:

The result of an obstruction that causes an excessive accumulation of cerebrospinal fluid.

hydroureteronephrosis:

Dilation and obstruction of a ureter, which results in dilation of the connected kidney.

hypemic hypoxia:

Hypoxia caused by a decrease in the blood's oxygen-carrying capacity due to a reduced amount of hemoglobin in the blood or a reduced number of red blood cells; also known as anemic hypoxia.

hyperangulated blade:

A video laryngoscope blade with a high degree of curvature to get around anatomic structures.

hyperbaric oxygen therapy (HBOT):

A treatment for decompression sickness and certain other conditions that involves placing the patient in a specially constructed chamber designed to withstand high internal pressures, well in excess of normal atmospheric pressures.

hyperbilirubinemia:

A condition commonly seen in the newborn, in which an excess of bilirubin develops in the blood; often leads to jaundice.

hypercalcemia:

An increased level of calcium in the blood.

hypercapnia:

Greater than normal amounts of carbon dioxide in the blood.

hyperchloremia:

An abnormally high level of chloride in the blood.

hyperdynamic state:

The first stage of distributive shock, which is characterized primarily by high cardiac output and low peripheral vascular resistance; also known as warm shock.

hyperemic:

An increase in blood flow into a tissue or organ; congested with blood.

hyperglycemia:

A condition in which the blood glucose concentration exceeds the normal range (70–100 mg/dL).

hyperkalemia:

An abnormally high level of potassium in the blood.

hyperosmolar hyperglycemic state (HHS):

A metabolic disorder that occurs principally in patients with type 2 diabetes and is characterized by hyperglycemia, hyperosmolarity, and the absence of significant ketosis; also known as hyperosmolar hyperglycemic nonketotic syndrome (HHNS).

hyperpnea:

A breath that is deeper than normal; it can lead to low levels of CO_2.

hypersensitivity:

A reaction consisting of an exaggerated or inappropriate immune response that occurs after a person comes in contact with a substance the body perceives as harmful.

hyperthyroidism:

A condition caused by increased production of T_3 (triiodothyronine) and T_4 (thyroxine) from the thyroid gland, resulting in an increase in the body's organ function; characterized by an increase in body temperature, gradual weight loss, increased and/or irregular heart rate, sweating, and irritability.

hypertrophy:

An increase in the size of the cells as the result of synthesis of more subcellular components, leading to an increase in tissue and organ size.

hyphema:

A collection of blood in the anterior chamber of the eye.

hypoalbuminemia:

An abnormally low level of albumin in the blood.

hypocalcemia:

A low level of calcium in the blood.

hypochloremia:

An abnormally low level of chloride in the blood.

hypodynamic state:

The second stage of distributive shock, which is characterized primarily by a subnormal temperature, a low white blood cell count, profound hypotension and hypoperfusion, and a sudden drop in cardiac output; also known as cold shock.

hypoglycemia:

A condition in which blood glucose drops below the normal range (70–100 mg/dL) and, in people without diabetes, is accompanied by signs and symptoms.

hypokalemia:

An abnormally low level of potassium in the blood.

hyponatremia:

An abnormally low level of sodium in the blood; a blood serum sodium level that is below 135 mEq/L, and a serum osmolarity level that is less than 280 mOsm/kg.

hypoplastic left heart syndrome:

A cyanotic heart defect that is caused by an abnormally small left ventricle; it is often associated with aortic and mitral valve stenosis or atresia.

hypopnea:

A shallow breath; it can lead to increased CO_2 levels and decreased oxygen levels.

hypothalamic-pituitary axis:

An interrelationship between the hypothalamus and the pituitary gland in which a releasing or inhibiting factor is sent from the hypothalamus to the pituitary, resulting in, respectively, an increase or decrease in metabolism and other functions throughout the body.

hypothalamo-hypophysial portal system:

The venules between the capillaries in the hypothalamus and pituitary gland by which the hypothalamus sends releasing or inhibiting factors to the pituitary gland, thereby increasing or decreasing metabolism, respectively.

hypothalamus:

An area of the cerebrum located below the thalamus that forms the floor and the anterior walls of the third ventricle, forming the most inferior portion of the diencephalon. It is responsible for the maintenance of homeostasis and the implementation of behavioral patterns and controls many body functions, including heart rate, digestion, sexual development, temperature regulation, emotion, hunger, thirst, and regulation of the sleep cycle.

hypothermia:

A condition in which the core body temperature decreases to less than 95°F (35°C).

hypothyroidism:

A condition caused by a deficiency of T_3 (triiodothyronine) and T_4 (thyroxine) from the thyroid gland, resulting in a slowing of the body's organ function; characterized by a decrease in body temperature, gradual weight gain, and increased risk for acute myocardial infarction and stroke.

hypotonia:

Low or poor (floppy) muscle tone.

hypovolemic shock:

A condition in which the circulating blood volume is inadequate for delivering sufficient oxygen and nutrients to the body; the most common cause of shock in pediatric populations.

hypoxemia:

An abnormally low oxygen level.

hypoxia:

A state of oxygen deficiency in the body, which is sufficient to cause an impairment of function. Hypoxia is caused by a reduction in the partial pressure of oxygen, inadequate oxygen transport, or an inability of the tissues to use oxygen.

hypoxic hypoxia:

Hypoxia caused by a decrease in the amount of oxygen in the blood due to a reduction in oxygen pressure in the lungs, a reduced gas exchange area, exposure to high altitude, or lung disease.

hypoxic ischemic encephalopathy (HIE):

Damage to cells in the central nervous system (the brain and spinal cord) from inadequate oxygen.

I time:

The time frame for the delivery of the tidal volume.

I:E ratio:

An expression for comparing the length of expiration to the length of inspiration. The normal ratio is 1:2, which means that expiration is twice as long as inspiration. This ratio is not measured in seconds.

iatrogenic response:

An adverse condition inadvertently induced in a patient by the treatment given.

idiosyncratic reaction:

An abnormal (and usually unexplained) reaction by a person to a medication to which most other people do not react.

ileus:

A lack of movement of GI contents in the absence of an obstruction, usually occurring postsurgery.

immediate hemolytic transfusion reactions:

Transfusion reactions that usually occur soon (between 1 and 2 hours) after the transfusion of incompatible red blood cells.

immunity:

Protection from infection, provided by a complex system of substances, cells, and tissues that exist to protect the human body from infection.

immunocompromised:

Unable to mount a normal immune response as the result of disease (eg, AIDS), chemotherapy treatment, or certain other medical treatments.

immunodeficiency:

An abnormal condition in which some part of the body's immune system is inadequate, such that resistance to infectious disease is decreased.

impedance:

Resistance to the flow of current along an electrical pathway, measured in ohms.

imperforate anus:

A congenital condition in which the anal opening is either absent or displaced.

implantable cardioverter-defibrillator (ICD):

A small, battery-powered electrical impulse generator that is implanted in patients at risk for sudden cardiac death as the result of ventricular fibrillation or pulseless ventricular tachycardia.

implantable pulse generator (IPG):

The largest implanted element in a pacemaking system, containing the battery and control circuitry.

implied consent:

The legal assumption made on behalf of a person who is unable to give consent that they would give consent if able to do so.

inborn error of metabolism:

A class of genetic diseases mostly caused by defects in single genes that code for enzymes that facilitate conversion of various substances into others; such defects lead to accumulation of substances that are toxic or interfere with normal function.

incidence:

The number of new cases of a disease within a defined population over a defined period of time.

incomplete breech:

A delivery presentation in which the buttocks present first and one foot extends into the birth canal.

incomplete spinal cord injury:

A disruption of the tracts of the spinal cord in which the patient retains some degree of cord-mediated function.

incorporation:

In the radiation context, a process in which radioactive materials enter the body during radiation exposure, causing ongoing internal exposure and creating devastating individual patient toxicity.

incubator:

An enclosed, clear plastic, heated bed that keeps the infant warm.

indication:

The reason for using a medication; it may be an official use, approved by the FDA, or an off-label use, for a purpose other than those specifically noted on the medication’s label.

indicator conditions:

Rare or unusual diseases associated with an immunocompromised state; also called AIDS-defining diseases.

indifferent stage:

The stage of altitude hypoxia in which the body is able to compensate for the hypoxia induced by low barometric pressures.

indirect bilirubin:

A by-product of the metabolism of red blood cells that is unconjugated and, therefore, not water soluble.

infection:

The invasion of normally sterile tissue by a pathogen.

inflammatory bowel disease (IBD):

Term covering two colon inflammation pathologies: ulcerative colitis and Crohn disease.

informed consent:

The process of proposing to the patient a course of action (assessment, treatment, transport), the risks associated with that action, the benefits associated with the action, and any reasonable alternatives, and then allowing the patient to decide if they want the provider to proceed with the action.

inhibition:

A condition in which the presence of one medication decreases the effect of another medication.

Injury Severity Score (ISS):

A trauma scoring system that adds the squares of the three highest abbreviated injury scale scores to create a score between 1 and 75 that accounts for multiple injuries, with 1 being a minor injury and 75 being an injury with a high mortality rate.

innate immune system:

The primary nonspecific antigen and immunogen defense mechanism that protects the host by eliminating microbes and other antigens in an effort to prevent infection and allergic reactions.

innate immunity:

The type of immunity that an individual is born with, such as that provided by the skin and mucous membranes.

inotropic:

Affecting the contractility of muscle tissue, especially cardiac muscle.

inspiration:

An active process in which gas is taken into the lungs.

inspiratory capacity (IC):

The maximum amount of air that can be inspired; the sum of the inspiratory reserve volume and the tidal volume.

inspiratory reserve volume (IRV):

The amount of air that can be inhaled after a tidal volume is inhaled.

instrument flight rules (IFR):

A mode of flight used when adverse weather conditions exist, visibility is poor, or cloud cover is low. The pilot may not be able to see outside the aircraft, must rely on instruments, and must be in constant contact with an air-traffic controller who assists in maintaining proper separation from other air traffic.

instrument meteorological conditions (IMC):

Weather conditions (eg, cloudiness or low visibility) in which a pilot must fly under instrument flight rules, depending on instruments to guide the aircraft.

insulin resistance:

A condition in which the pancreas produces enough insulin but the body cannot effectively use it.

interfacility transport (IFT):

The transport of a patient between two health care facilities.

interference:

A direct biochemical interaction between two drugs.

intermediate-level disinfection:

Treatment used on inanimate objects that kills *Mycobacterium tuberculosis,* vegetative bacteria, and most viruses and fungi, but does *not* kill bacterial spores.

internal capsule:

A massive bundle of efferent and afferent fibers connecting the various subdivisions of the brain and spinal cord.

International Civil Aviation Organization (ICAO):

An agency of the United Nations that defines standards for international air navigation and, as part of its role in developing safe practices, requires crew resource management.

international normalized ratio (INR):

A comparative rating of a patient’s prothrombin time to help standardize the prothrombin time when planning treatment.

intervertebral foramen:

A space in the middle of the vertebra that allows the exit of a peripheral nerve root and spinal vein as well as the entrance of a spinal artery on both sides at each vertebral junction.

intra-abdominal hypertension (IAH):

Sustained increased abdominal pressure of more than 12 mm Hg.

intra-abdominal pressure (IAP):

The static pressure inside the abdominal compartment; normally 5 mm Hg, with variations caused by respirations.

intra-aortic balloon pump (IABP) therapy:

A procedure involving insertion of a balloon into the descending thoracic aorta and its connection to a pump via a catheter; this therapy helps to increase blood flow to the coronary arteries during diastole (inflation) and decrease the afterload of blood from the left ventricle (deflation).

intra-atrial conduction delay (IACD):

Delayed conduction within one of the atria, often associated with left or right atrial enlargement.

intra-atrial pathways:

The anterior or Bachman bundle, middle bundle, and posterior internodal system, through which the electrical impulse passes after the sinoatrial node; represented by the P wave on the electrocardiogram; also called intranodal pathways.

intracerebral hemorrhage:

Direct bleeding into the brain parenchyma.

intracranial pressure (ICP):

The pressure exerted by brain tissue, intracranial vascular contents, and cerebrospinal fluid in the closed, nondistensible cranial cavity.

intracranial temperature (ICT):

Core brain temperature or homeostatic mean gradient temperature of 101.1°F (38.4°C).

intrarenal acute kidney injury:

A type of acute kidney injury caused by damage to an actual nephron.

introitus:

The visible opening to the vagina.

intussusception:

An event in which one part of the intestine telescopes into another part of the intestines, leading to a blockage.

invasive hemodynamic monitoring:

Methods for assessing the physiologic condition of the three principal components of the cardiovascular system: heart, vascular network, and fluid volume. It mainly not only assesses the capability of a patient’s heart to pump the requisite amount of blood to the body but also can assess compliance, tone, resistance of the vascular network, and fluid status; it includes a variety of pressure values and other measurements.

invasive ventilation:

Application of mechanical ventilation through an artificial airway such as a tracheostomy or endotracheal tube.

involuntary (autonomic) nervous system:

The sympathetic and parasympathetic branches of the nervous system, whose fibers connect the structures of the CNS with smooth muscle, cardiac muscle, and glands.

ionic bond:

A type of chemical bond formed between oppositely charged ions.

ionized calcium:

Calcium that is not bound or chelated; also called free calcium. Its value is useful in assessing for renal failure, nephrotic syndrome, acid–base derangements, and decreases or elevations in chelating compounds.

irradiated blood products:

Blood products in which lymphocyte DNA has been exposed to radiation to damage it, and thereby limit the cells’ ability to replicate and cause the rare but often fatal condition of transfusion-associated graft-versus-host disease.

irradiation:

Exposure to radiation. It is important to distinguish between irradiation and contamination because health care providers and emergency responders are not placed at any risk by patients who have been irradiated but are not contaminated.

ischemic colitis:

A potentially life-threatening form of colitis that results from diminished blood flow to the GI tract.

ischemic stroke:

A condition in which an artery to the brain becomes blocked by a thrombus, embolus, trauma, or vasospasm (often due to drugs).

isoelectric:

When referring to a wave, the status of the wave as neither positive nor negative.

isolation precautions:

Measures taken to prevent contact with pathogens, including airborne, droplet, and contact precautions.

isovolumetric contraction:

The early stage of ventricular contraction during which ventricular blood volume is unchanging because all valves are closed (the semilunar valves have not yet opened).

isovolumetric relaxation:

The early stage of ventricular relaxation during which ventricular blood volume is unchanging because all valves are closed (the atrioventricular valves have not yet opened).

Jackson-Pratt drain:

A surgical drain used to remove fluid buildup from the wound site during the postoperative healing process.

jaundice:

The deposition of bile pigments in the skin; associated with hyperbilirubinemia.

jejunostomy tube (J tube):

A feeding tube placed through the abdominal wall into the jejunum.

joule:

A unit of measurement for energy.

jugular venous bulb oximetry:

A technique in which a sampling catheter is placed in the internal jugular vein and directed upward so that its tip rests in the jugular venous bulb at the base of the brain; samples of blood can then be drawn to measure mixed venous oxygen saturation (Svo_2).

just culture:

A system of beliefs and practices that focuses on blamelessly identifying issues that lead to errors or unsafe behaviors, while still maintaining individual accountability for reckless behavior.

Kehr sign:

Left shoulder pain that may indicate a ruptured spleen. (Right shoulder pain may indicate trauma to the liver.) This referred pain stems from diaphragm irritation by intra-abdominal bleeding.

Kernig sign:

Resistance and pain elicited on extension of the leg at the knee, with the patient in the supine position and the hips flexed perpendicular to the trunk; when pain occurs as a result of this test, the test result is positive.

ketone bodies:

Organic products of fat catabolism—specifically, acetoacidic acid, acetone, and beta-hydroxybutyric acid.

ketonuria:

The presence of ketone bodies in the urine.

Kussmaul respiration:

A typical respiratory pattern seen in patients with metabolic acidosis; it is characterized by a high respiratory rate and high tidal volume, leading to increased minute ventilation.

lactate:

The form of lactic acid that is physiologically present in the body.

lactate dehydrogenase (LDH):

An enzyme that catalyzes the metabolism of pyruvate (the end product of glycolysis) to lactate in the absence of a functioning citric acid cycle.

lactic acidosis:

A form of acidosis caused by an excess accumulation or impaired excretion of lactate, leading to an elevated anion gap; it can result from exposure to various toxic substances, inadequate tissue perfusion in various shock states, dysfunction of certain organs, nutritional deficiency, infection, malignancy, diabetes, or hereditary metabolic disorders.

laparoscopic adjustable gastric banding (LAGB):

The least invasive bariatric surgical procedure, in which an adjustable band is placed around the upper portion of the stomach, with an adjustment port located on the right side of the abdomen, under the skin.

laryngeal mask airway (LMA):

A rescue airway with a basic design similar to an endotracheal tube at the proximal end, in that a standard adapter is present to allow ventilation. The distal end is equipped with an elliptical cuff, which, when inflated, covers the supraglottic area and allows ventilation.

latent error:

A mistake that is likely to occur secondary to organizational or design failures that allow the inevitable active error to cause harm.

lead:

In the context of the 12-lead electrocardiogram, the designated position of the electrode, or the name of the electrode placement. In the context of a pacemaker, an insulated wire that carries signals in a pacemaking system between the implantable pulse generator and the heart tissue.

Lean:

A strategy that looks at all processes and attempts to reduce waste and ensure all activities add value.

Le Fort criteria:

A categorization of facial fractures involving the maxilla in which the fractures are differentiated based on the location of fracture lines and the extent of mobility of facial structures on physical examination.

left anterior fascicle:

The portion of the electrical conduction system responsible for innervating the anterior and superior areas of the left ventricle. It is a single-stranded cord terminating in the Purkinje cells.

left posterior fascicle:

The portion of the electrical conduction system responsible for innervating the posterior and inferior areas of the left ventricle. It is a widely distributed, fanlike structure terminating in the Purkinje cells.

left ventricular assist device (LVAD):

A means of mechanical circulatory support in which a pump is implanted in the patient’s chest to help circulate blood from the left ventricle of the heart to the rest of the body.

left ventricular end-diastolic pressure:

The pressure exerted on the left ventricle at the end of diastole; the normal value is 4 to 12 mm Hg and is measured by using a pulmonary artery catheter.

left ventricular stroke work index:

A calculation of the contractility of the left ventricle indexed to the patient’s body surface area; equivalent to the stroke volume index.

leukocytosis:

An abnormally high number of white blood cells.

leuko-reduced blood products:

Blood products in which the white blood cells and platelet fragments have been filtered from donated blood products.

leukotrienes:

A class of biologically active compounds that occur naturally in leukocytes and that produce allergic and inflammatory reactions.

leveling:

The process of ensuring that the hemodynamic pressure transducer is at the level of the atrium, which also corresponds to the level of the aortic root.

Lhermitte phenomenon:

A condition in which forward flexion of the neck produces an electric shock feeling, usually running down the back.

lift:

The upward force created by the wings moving through the air, which sustains the aircraft in flight.

ligament of Treitz:

A small ligament supporting the small intestine at the junction between the duodenum and the jejunum. It serves as the dividing point between the upper and lower GI tract.

limbic lobe:

Part of the temporal lobe that is the seat of emotions and instincts; also called the rhinencephalon.

limb leads:

The electrocardiography lead electrodes attached to the limbs that form the hexaxial system, dividing the heart along a coronal plane into the anterior and posterior segments.

linea nigra:

A dermatologic condition affecting pregnant women in which a darkened line develops from the navel to the vagina.

linear skull fracture:

A type of skull fracture characterized by a single fracture line.

linear stellate fracture:

A fracture with multiple linear fractures radiating from the site of impact.

lines of cleavage:

Regions between interlocking collagen fibers that run in various planes, usually parallel to the skin; they run longitudinally in the skin of the head and limbs and in a circular pattern around the neck and trunk and are used when deciding where to make incisions for escharotomies and fasciotomies.

lipase:

A pancreatic hormone that metabolizes lipids.

lipid disorders:

A group of disorders that cause a change in the production or use of cholesterol and may also alter the way cholesterol circulates or is processed in the body.

lithotripsy:

Use of external vibrations to break up gallstones.

liver function test (LFT):

A test for liver damage that measures enzymes that normally appear in liver cells but may spill out into the vasculature with parenchymal damage.

long QT syndrome (LQTS):

A prolonged QT interval on the electrocardiogram that is primarily caused by a congenital disorder. Under certain conditions, it tends to deteriorate into ventricular tachyarrhythmias and can lead to syncope or sudden cardiac death; the patient loses consciousness, often without warning.

low-level disinfection:

Treatment used on inanimate objects that kills most bacteria, some viruses, and some fungi, but does *not* kill *Mycobacterium tuberculosis* or bacterial spores.

lumbar puncture:

A procedure in which a needle is inserted first into the lumbar portion of the back and then into the subarachnoid space to obtain spinal fluid for testing or to administer drugs.

Lund-Browder chart:

A detailed version of the rule of nines chart that takes into consideration the changes in body surface area that occur with growth.

magnetic resonance imaging (MRI):

A noninvasive diagnostic imaging technique that uses a powerful magnet to align water molecules present in body compartments to visualize the internal structure and function of the body; a three-dimensional image is obtained from this alignment and the speed at which molecules alter or release.

major burn:

According to the American Burn Association classification system, any of the following: (1) partial-thickness burns involving more than 25% of total body surface area (TBSA) in adults or 20% of TBSA in children younger than 10 years and adults older than 40 years; (2) full-thickness burns involving 10% or more of TBSA; (3) burns involving the face, eyes, ears, hands, feet, or perineum that may result in functional or cosmetic impairment; (4) high-voltage electrical injury; (5) burns complicated by inhalation injury or major trauma; and (6) burns sustained by high-risk or debilitated patients.

malignant hyperthermia:

A condition that may occur after administration of certain inhaled anesthetics (notably succinylcholine); characterized by muscle spasms, rigidity, acidosis, hypercarbia, hyperthermia, tachycardia, tachypnea, myoglobinuria, rhabdomyolysis, and hyperkalemia.

Mallampati classification:

A system for predicting the relative difficulty of intubation based on the amount of oropharyngeal structures visible in an upright, seated patient who is fully able to open their mouth.

Mallory-Weiss syndrome:

Laceration and bleeding of the esophagus, often following forceful vomiting.

malrotation:

A congenital anomaly of rotation of the midgut, in which the small bowel is found predominantly on the right side of the abdomen.

massive transfusion protocol:

The rapid administration of large amounts of blood products in fixed ratios (usually 1:1:1) for the management of hemorrhagic shock.

mean airway pressure (MAP):

The amount of positive pressure in the airway, averaged over the inspiratory and expiratory phases of the breathing cycle.

mean arterial pressure (MAP):

The average arterial pressure during a single cardiac cycle; the mean between the systolic and diastolic blood pressures (SBP and DBP): $\text{MAP} = \text{DBP} + (\text{SBP} - \text{DBP})$.

mean electrical axis:

The sum of all electrical impulses.

mechanical circulatory support (MCS):

Mechanical interventions aimed at augmenting or replacing the native cardiac output from the heart; also called mechanically assisted circulation, mechanical circulatory systems, and ventricular assist devices.

mechanical ventilation:

The application of a device that provides varying degrees of ventilatory support.

mechanism of action:

The way in which a medication produces the intended response.

meconium:

A dark green fecal material that accumulates in the fetal intestines and is discharged around the time of birth.

meconium aspiration syndrome:

The respiratory distress caused by meconium aspiration, which can lead to atelectasis in the lungs, persistent pulmonary hypertension (delayed transition from fetal to neonatal circulation), pneumonitis, and pneumothorax.

medical control:

The oversight designed to ensure that actions taken by providers on behalf of patients are appropriate. It is divided into direct (online) medical control, which is available in real time via radio or mobile phone, and indirect (off-line) medical control, such as standing orders and protocols.

medical direction:

Supervision of medical care by a physician empowered to authorize and review CCTPs, usually through protocols, standing orders, education, and quality improvement efforts.

medical director:

A physician who provides guidance and oversight for the practice of a critical care transport service's personnel.

medical error:

The failure of a planned health care action to be completed as intended, or the use of a wrong care plan to achieve an aim.

medical screening exam:

An exam that is legally required when the patient is within 250 yards of the hospital, or on hospital property, and is seeking treatment for an emergency medical condition; it must be performed by a physician, physician assistant, or nurse practitioner.

medulla oblongata:

The lowermost portion of the brainstem.

melena:

Black, tarry stool containing partially digested blood, with the bleeding usually originating from the upper GI tract.

meningitis:

An umbrella term referring to five types of inflammation of the leptomeninges, the membranes that cover and enclose the spinal cord and brain.

metabolic acidemia:

A condition characterized by the body’s production of excessive quantities of acid or the kidneys’ inability to remove enough acid from the body.

metabolic acidosis:

A pathologic condition characterized by a blood pH of less than 7.35, which is caused by an accumulation of acids in the body from a metabolic cause; can be caused by any number of systems in the body, including the gastrointestinal system, or by major organ failure.

metabolic alkalosis:

A pathologic condition (blood pH > 7.45) resulting from an accumulation of bases in the body caused by any number of systems in the body, including the gastrointestinal system, or by major organ failure.

metabolic syndrome:

A group of risk factors that together may lead to coronary artery disease, stroke, and type 2 diabetes; usually related to a predisposition to a lipid disorder.

microaxial continuous-flow pump:

A means of temporary circulatory support that consists of an axial-flow pump mounted on a catheter that is typically inserted through the femoral artery and connected to a bedside console.

microcirculation:

Circulation that occurs in the microvasculature, the body’s smallest vessels (arterioles, capillaries, and venules).

midbrain:

A small area of the brainstem extending between the diencephalon, the pons, and the third ventricle.

mild hypothermia:

A condition in which the core body temperature is between 90°F and 95°F (32.2°C and 35°C); at this stage of hypothermia, the body usually compensates with increased thermogenesis and interrupted thermolysis.

mild TBI:

Concussion; a traumatically induced physiologic disruption of brain function that occurs without structural damage.

Mini-Mental State Examination:

A simple, easily applied test of higher cognitive functions.

Minnesota esophagogastric tamponade tube:

A tube that is placed to stop bleeding of esophageal varices. It is similar to the Sengstaken-Blakemore tube, but has a built-in suction catheter.

minor burn:

According to the American Burn Association classification system, any of the following: (1) partial-thickness burns involving less than 15% of total body surface area (TBSA) in adults or 10% of TBSA in children younger than 20 years and adults older than 50 years; and (2) full-thickness burns involving 2% or less of TBSA that do not present a serious threat of functional or cosmetic risk to the eyes, ears, face, hands, feet, or perineum.

minute volume:

Total volume of air breathed in and out in 1 minute. It is calculated by multiplying the respiratory rate per minute by the tidal volume.

mistake:

A situation in which an action occurs as intended but is the wrong action; it often occurs secondary to lack of experience, insufficient training, or negligence.

mixed acidosis:

A pathologic condition in which there is a low pH (<7.35), an elevated P_{CO_2} level (>45 mm Hg), and a low bicarbonate level (<22 mmol/L); it occurs when both respiratory and metabolic acidosis are present at the same time.

mixed alkalosis:

A pathologic condition in which there is an elevated pH (>7.45), a low P_{CO_2} level (<35 mm Hg), and an elevated bicarbonate level (>26 mmol/L); it occurs when both respiratory and metabolic alkalosis are present at the same time.

mixed central venous oxygen saturation ($Scvo_2$):

The percentage of oxygen bound to hemoglobin in blood returning to the right side of the heart from the head and upper body, which is representative of oxygen extraction from the blood by the head and upper extremities.

mixed venous oxygen saturation (Svo_2):

The percentage of oxygen bound to hemoglobin in blood returning to the right side of the heart, which is representative of global oxygen extraction from the blood and is normally in the range of 50% to 75%.

mobile intensive care units:

Ambulances or helicopters that are used only for maintaining specialized or intensive care treatment; they are used primarily for interfacility transports.

mode:

The particular way in which a spontaneous or mechanical breath is delivered.

moderate burn:

According to the American Burn Association classification system, any of the following: (1) partial-thickness burns involving 15% to 25% of total body surface area (TBSA) in adults or 10% to 20% of TBSA in children younger than 10 years and adults older than 40 years and (2) full-thickness burns involving 10% or less of TBSA in patients younger than 50 years that do not present a serious threat to functional or cosmetic impairment of the eyes, ears, face, hands, feet, or perineum.

moderate hypothermia:

A condition in which the core body temperature is between 82°F and 90°F (27.7°C and 32.2°C); mental status is markedly decreased, and shivering may still be present but is less vigorous and unlikely to be an effective from of thermogenesis.

monoclonal antibodies:

Antibodies in which large quantities of an antibody from a single B-cell clone are produced to protect against a specific pathogen.

Monro-Kellie doctrine:

A theory developed by two Scottish anatomists, who stated that the central nervous system is enclosed in a rigid compartment along with cerebrospinal fluid, whose total volume tends to remain constant; an increase in any component—whether brain, blood, or CSF—will cause an increase in pressure and decrease the volume of one of the other elements.

morbidity:

An illness or an abnormal condition or quality; the rate at which an illness occurs in a particular area or population, usually expressed as the number of nonfatal injuries in a certain population in a given time period divided by the size of the population.

morbid obesity:

A body mass index of 40 kg/m^2 or higher. Morbid obesity not only includes all of the health risks associated with obesity but also makes essential functions such as walking or breathing difficult.

Moro reflex:

An infant reflex in which, when an infant is caught off guard, the infant opens their arms wide, spreads the fingers, and seems to grab at things.

mortality:

The condition of being subject to death, caused by injury and disease; the number of deaths per unit of population in any specific region, age group, disease, or other classification, usually expressed as the number of deaths in a certain population in a given time period divided by the size of the population.

motor area:

Part of the frontal lobe containing pyramidal cells that control voluntary motor function on the opposite side of the body.

mucosa:

The outermost layer of the alimentary canal. It consists of three sublayers: surface epithelium, lamina propria, and muscularis mucosae.

multiple organ dysfunction syndrome (MODS):

Altered organ function in acutely ill patients, which is diagnosed when two or more organs stop functioning.

Murphy sign:

A painful reaction elicited by asking the patient to take and hold a deep breath as the provider palpates the right subcostal area; if pain occurs on inspiration, when the inflamed gallbladder comes in contact with the provider’s hand, Murphy sign is positive. It may signal the presence of gallbladder problems.

muscularis externa:

The third tissue layer of the alimentary canal. It contains two levels in most places: the circular layer and the longitudinal layer.

myocardial oxygen consumption (MV_{O_2}):

The volume of oxygen that the heart muscle consumes; an expression of the level of oxygen demand in the heart.

myoglobinuria:

The presence of myoglobin, a respiratory pigment of muscle tissue, in the urine.

myxedema coma:

A rare, life-threatening condition that can occur in patients who have severe, untreated hypothyroidism, and that is characterized by altered mental status and lethargy, failure of the thermoregulatory system, and a precipitating event; may be accompanied by auditory and visual hallucinations, seizures, or unresponsiveness.

National Transportation Safety Board (NTSB):

An independent federal agency that promotes transportation safety, including aviation, railroad, highway, maritime, pipeline, and hazardous materials safety; it investigates transportation crashes to identify the cause and make safety recommendations.

NBG codes:

North American Society of Pacing and Electrophysiology/British Pacing and Electrophysiology Group Generic codes; five-letter codes used to categorize pacemakers by their functions and capabilities, developed by a joint effort of North American and British electrophysiology groups.

near miss:

An unplanned event that did not cause an injury, illness, or damage, but had the potential to do so; it is indistinguishable from a full-fledged adverse event in all but the outcome.

necrotizing enterocolitis (NEC):

A disorder seen predominantly in premature infants in which the bowel experiences necrosis (tissue death).

necrotizing fasciitis:

A limb- or life-threatening infection of the soft tissue that affects the subcutaneous tissues, fat, and fascia.

negative-pressure ventilators:

Mechanical ventilators that operate using pressure that is less than the ambient (atmospheric) pressure.

negligence:

Failure to provide the same quality of care (as defined by applicable standards) that is reasonably expected for a provider to give under similar circumstances. Negligence is established when the plaintiff proves four elements: duty to act, breach of the duty, injury to the patient, and the breach as the direct cause of the injury.

neonate:

An infant during the first 28 days after birth.

nephrolithiasis:

A condition in which the body produces renal calculi (kidney stones), which are often symptomatic as they travel through the ureters; may produce impaction and infection of the urinary tract.

neurocranium:

The part of the skull that encloses and protects the brain.

neurogenic shock:

Circulatory failure caused by paralysis of the nerves that control the size of the blood vessels, leading to widespread dilation and consequent hemodynamic and systemic effects; it is seen in spinal cord injuries.

neuroleptic malignant syndrome (NMS):

A potentially fatal reaction to antipsychotic and neuroleptic medications; characterized by patient hyperthermia, profound muscle rigidity, autonomic dysfunction, metabolic acidosis, and confusion.

neuromuscular-blocking agents (NMBAs):

Medications that bind to acetylcholine receptors, thereby inhibiting the action of acetylcholine; this effect blocks transmission at the neuromuscular junction and causes paralysis of the muscles.

neutral thermal environment:

The temperature at which maintenance of normal body temperature requires only minimal metabolic expenditure.

neutropenia:

An abnormally low neutrophil count.

neutrophils:

A type of leukocyte (white blood cell); these numerous phagocytic microphages usually are the first of the mobile phagocytic cells to arrive at the site of injury or infection.

never event:

An event that should never occur and indicates a serious underlying safety problem.

newborn:

An infant within the first few hours after birth.

nicotinic receptors:

Cholinergic receptors that bind with the neurotransmitter acetylcholine.

nitrogen narcosis:

A state resembling alcohol intoxication, which is produced by nitrogen gas dissolved in the blood at high ambient pressure.

nonalcoholic fatty liver disease (NAFLD):

Accumulation of fat in the liver, for which alcohol consumption is not believed to be a contributing factor.

nondepolarizing agent:

A medication designed to cause temporary paralysis by binding in a competitive but nonstimulatory manner to part of the acetylcholine receptor; these medications do not cause fasciculations and have a longer duration of action than succinylcholine does.

nonfunctioning adenoma:

A type of pituitary lesion in which the tumor does not secrete any hormones.

noninvasive ventilation:

Application of mechanical ventilation through a mask, mouthpiece, or other interfaces other than an artificial airway.

normalization of deviance:

A process in which a shift away from acceptable policies and practices becomes the behavioral norm.

normal-pressure hydrocephalus (NPH):

An accumulation of CSF that causes the ventricles of the brain to enlarge. The enlarged ventricles of a patient with this condition may not cause increased intracranial pressure.

normal range:

A range of values encompassing the results that 95% of healthy people would have for the particular test.

nosocomial:

Infections acquired during hospitalization or a nursing home stay.

nuchal rigidity:

Marked resistance to head movement in any direction that is suggestive of meningeal irritation.

obesity:

A body mass index greater than or equal to 30 kg/m^2.

obstructive diseases:

Diseases that result in difficulty with moving air out of the lungs, such as asthma, chronic obstructive pulmonary disease, cystic fibrosis, and bronchiectasis.

occipital lobe:

The lobe of the brain that occupies the most posterior portion of the cerebrum; it is the primary receptive area for vision, specifically the interpretation of visual stimuli.

off-line medical direction:

Medical direction given through a set of protocols, standing orders, educational programs, policies, and/or standards.

Ohm's law:

The principle given by the equation $V = IR$, which states that applied voltage is equal to the current times the resistance of the circuit.

oligohydramnios:

Decreased volume of amniotic fluid during a pregnancy; a risk factor associated with abnormalities of the urinary tract, postmaturity (birth after a prolonged pregnancy), and intrauterine growth retardation.

omphalocele:

Herniation of abdominal contents into the base of the umbilical cord.

online medical control/consultation (OLMC):

Immediate medical direction provided to critical care transport professionals in outlying locations by a physician; a system in which field personnel contact an emergency department physician via telephone or radio for a consult.

online medical direction:

Medical direction in which the care provider is in direct contact with a physician, usually via two-way radio or telephone.

onset of action:

The time needed for the concentration of a medication at the target tissue to reach the minimum effective level.

oophoropexy:

Surgery in which the ovary is attached to the pelvic sidewall so it cannot twist on itself.

open pneumothorax:

A communicating chest wound, in which air enters the pleural space from the environment; also called a sucking chest wound.

opioids:

The class of chemicals that includes naturally derived opiates and newer synthetic medications with the same properties.

opioid syndrome:

Toxicity that develops following illicit use and abuse of opioids or as an adverse consequence of a therapeutic error or accidental ingestion of opioids and characterized by CNS and respiratory depression.

opsonization:

The process of making bacterial cells more susceptible to the action of phagocytosis by the action of binding an antibody to the pathogen’s cell membrane.

optic disk:

The most prominent structure visible in the eye; it represents the termination of the optic nerve.

osmolarity:

The amount of dissolved substance in 1 L of water.

osmosis:

The diffusion of water across membranes.

osmotic pressure:

The pressure created in a space divided by a semipermeable membrane owing to differences in concentrations of solutes found in the solutions on either side of the membrane.

osteogenesis imperfecta:

A congenital disorder in which the individual has brittle bones that are susceptible to fracture; also known as brittle bone disease or Lobstein syndrome.

osteopetrosis:

An inherited disorder in which the bones become extremely hard and dense.

ostomy:

A surgically created opening through which feces can be voided in the absence of some or all of the large intestine or rectum.

ovarian cyst:

A fluid buildup within an outcropping of tissue from the ovary. If such a cyst ruptures, significant bleeding can occur.

ovarian torsion:

Twisting of an ovary about its ligaments, resulting in ischemia and possibly necrosis.

overweight:

A body mass index of 25 to 29.9 kg/m^2.

oxygen consumption (O_2):

The amount of oxygen used by the cells and tissues.

oxygen delivery (Do_2):

The amount of oxygen delivered to the tissues each minute.

oxygen extraction fraction (OEF):

The fraction of oxygen extracted from the blood as it passes by to maintain normal oxygen delivery and, consequently, normal brain functions.

oxygen extraction ratio (ERo_2):

The relationship between oxygen consumption and oxygen delivery; a measure of the cells' ability to use oxygen.

oxygen hood:

A tent that is placed over the head of an infant for the purpose of delivering supplemental oxygen.

P mitrale:

A double-humped, M-shaped P wave that is 120 ms wide or greater, with the tops of the humps 40 ms apart or greater. Found in limb leads I, II, and III, it represents left atrial enlargement.

P pulmonale:

A tall P wave that is 2.5 mm high or greater. Found in leads II and III, it indicates right atrial enlargement.

pacemaker syndrome:

The occurrence of symptoms relating to the loss of atrioventricular synchrony in ventricularly paced hearts or symptoms caused by inadequate timing and ventricular contractions in paced hearts.

pacing circuit:

The conduction pathway along which the pacing impulse flows; formed by a power source, one or two lead–electrode pairs, and body tissue.

pacing impulse:

The electrical impulse sent to the heart to stimulate the heart to beat.

packed red blood cells (PRBCs):

A blood product that retains all of the characteristics of whole blood, with the exception of the extraction of approximately 250 mL of platelet-rich plasma from each unit of whole blood.

pallor:

Skin presentation suggestive of reduced blood flow or oxygenation. In patients with light skin, paleness typically presents as unusual lightness compared with the person’s baseline skin color. In patients with dark skin, pallor may appear as ashen or gray skin on general assessment. In general, the mucous membranes inside the inner lower eyelid and the oral mucosa will have a pink coloration in all healthy patients, regardless of skin color; thus, a white or pale appearance of these areas in any patient suggests reduced blood flow or oxygenation.

palpable purpura:

Relatively large (greater than 3 mm) areas of bleeding under the skin.

pancreatitis:

Inflammation of the pancreas leading to autodigestion, tissue destruction, and impaired function.

pandemic:

A worldwide epidemic.

panel:

Groups of related tests that are performed as a single unit; also called a profile.

papillary muscles:

A type of muscle in the ventricle from which the chordae tendineae extend and attach to the cusps of the atrioventricular valves.

paracentesis:

Insertion of a needle into the abdomen to aspirate ascites; often done to diagnose spontaneous bacterial peritonitis.

parietal lobe:

The lobe of the brain situated directly posterior to the frontal lobe on the other side of the central fissure; it is largely responsible for sensory functions.

Parkland formula:

A formula that recommends giving 4 mL of lactated Ringer solution or normal saline for each kilogram of body weight, multiplied by the percentage of body surface area burned; sometimes used to calculate fluid needs during lengthy transport times.

paroxysmal nocturnal dyspnea:

Severe shortness of breath occurring at night after several hours of recumbency, during which fluid pools in the lungs; the person is forced to sit up to breathe. It is caused by left-side heart failure or decompensation of chronic obstructive pulmonary disease.

paroxysmal supraventricular tachycardia:

A supraventricular tachycardia that starts and ends abruptly.

partial pressure of oxygen (arterial) (Pao_2):

The amount of the total pressure in the blood contributed by oxygen; a value measured when analyzing the arterial blood gas level.

partial pressure of oxygen (Po_2):

A measurement of the amount of oxygen dissolved in the blood.

partial-thickness burn:

A burn that involves the epidermis and part of the dermis, characterized by pain and blistering; also called a second-degree burn.

partial thromboplastin time (PTT):

A value that represents the intrinsic coagulation pathway's clotting ability; also known as activated partial thromboplastin time (aPTT).

passive immunity:

Short-lived immunity acquired from placental transfer, antibodies in the mother's milk, or antiserum administered intravenously.

passive warming:

A method of warming a hypothermic patient without the introduction of exogenous heat sources. It involves removing cold, wet clothing; drying the patient if necessary; and wrapping the patient in layers that retain radiant heat, minimize conductive heat loss, and protect from ambient moisture such as rain or snow.

patent ductus arteriosus (PDA):

A condition in which the ductus arteriosus, which assists in fetal circulation, does not transition as it should after birth to become the ligamentum arteriosum. The result is that the connection between the pulmonary artery and the aorta remains open, allowing some oxygenated blood to move back into the heart rather than all of it moving out of the aorta and into the systemic circulation.

pathogens:

Microorganisms that activate the immune system and cause disease; they include viruses, parasites, fungi, and bacteria.

patient safety:

According to the World Health Organization, freedom from unnecessary harm or potential harm associated with health care.

peak airway pressure:

The amount of positive pressure generated by the ventilator to deliver the tidal volume.

peak inspiratory pressure (PIP):

The greatest volume of air delivered to the lungs during inhalation.

pediatric assessment triangle (PAT):

An assessment tool that allows rapid formation of a general impression of the type and level of illness or injury in an infant or child without touching the patient; consists of assessing appearance, work of breathing, and circulation of the skin.

pelvic inflammatory disease (PID):

An infection of the female upper organs of reproduction—specifically, the uterus, ovaries, and fallopian tubes.

penile fracture:

A rupture of one of the blood-containing sacs in the penis, resulting in deformity and possible loss of function.

peptic ulcer:

An erosion of the mucosal lining of the GI tract.

percutaneous endoscopic gastrostomy (PEG) tube:

A feeding tube that is placed through the abdominal wall into the stomach.

perfusion:

The circulation of oxygen and nutrients at the cellular level and removal of waste products of metabolism for elimination.

perfusionists:

Highly trained technicians who are intimately familiar with the operation of intra-aortic balloon pumps and adult and pediatric extracorporeal membrane oxygenation machines, and who may assist during any medical situation, including critical care transports, in which it is necessary to support or temporarily replace a patient’s circulatory or respiratory function.

pericardial tamponade:

Impairment of diastolic filling of the right ventricle as a result of significant amounts of fluid in the pericardial sac surrounding the heart, leading to a decrease in the cardiac output.

pericardiocentesis:

A procedure in which a needle or angiocatheter is introduced into the pericardial sac to relieve cardiac tamponade.

pericarditis:

An inflammatory process involving the pericardium.

peripheral blood smear:

A glass slide containing a drop of blood that can be used to microscopically examine the structure of the blood cells.

peristalsis:

A general term describing wavelike muscular contractions of tubular organs, which carry forward materials or liquids contained in those organs.

peritoneal dialysis (PD):

Dialysate solution injected into the abdomen, using the peritoneum as a natural semipermeable membrane to separate solutes.

peritonitis:

Inflammation of the peritoneum; typically results in generalized abdominal tenderness and guarding.

persistent pulmonary hypertension (PPHN):

The persistence of elevated pressures in the pulmonary vasculature after birth, associated with failure to transition from the fetal circulation to the postpartum or normal newborn circulation.

petechial lesions:

Small areas of bleeding under the skin (pinpoint).

pharmacodynamics:

The branch of pharmacology that studies reactions between medications and living structures, including the processes of body responses to pharmacologic, biochemical, physiologic, and therapeutic effects.

pharmacokinetics:

The study of the metabolism and action of medications, with the particular emphasis on the time required for absorption, duration of action, distribution in the body, and method of excretion.

pharmacology:

The study of the preparation, properties, uses, and actions of medications.

pheochromocytoma:

A catecholamine-producing benign tumor of chromaffin cells located in the center of the adrenal gland, which can occur either sporadically or chronically as a result of genetic risk factors; it causes stimulation of alpha-adrenergic and beta-adrenergic receptors, resulting in hypertension, increased cardiac contractility, glycogenolysis, gluconeogenesis, intestinal relaxation, and increased heart rate.

phlebitis:

Inflammation, swelling, and pain along the veins that can lead to the formation of blood clots and thrombophlebitis (venous inflammation associated with a thrombus).

phlebostatic axis:

An imaginary point located at the fourth intercostal space, mid-chest level, which serves as an external landmark for the right atrium.

phonation:

The process by which the vocal cords create sound.

phosphate buffer system:

The buffer system that functions in the renal tubules and intracellular fluids to convert strong acids or bases into weak acids or bases so that they have a minimal effect on the body’s overall pH.

phosphodiesterase:

An enzyme that helps break phosphodiester bonds, creating smaller nucleotides.

physician orders for life-sustaining treatment (POLST):

A legal document that establishes in advance what care a person wants, and does not want, in the event that they are unable to consent to care at the time.

physiologically deficient zone:

The zone that extends from 10,000 to 50,000 feet. Noticeable physiologic deficits occur above 10,000 feet. A decrease in barometric pressure results in oxygen deficiency, causing hypoxic hypoxia; the manifestation of trapped and evolved gases then occurs. The use of pressurized aircraft and/or supplemental oxygen is necessary in this zone.

physiologic zone:

The atmospheric zone that extends from sea level to 10,000 feet; the area of the atmosphere to which humans are well adapted. The barometric pressure is sufficient in this zone to facilitate adequate oxygenation. The changes in pressure encountered with rapid ascents or descents within this zone can produce ear or sinus trapped-gas problems.

pia mater:

The innermost layer of the meninges, which rests directly on the brain or spinal cord.

Pickwickian syndrome:

A hypoventilation syndrome associated with obesity in which the person may experience increased breathing difficulty when in the supine position and have a higher incidence of sleep apnea, snoring, and hypercapnia.

Pierre Robin syndrome:

A condition present at birth marked by a very small lower jaw (micrognathia) and a cleft palate; the tongue tends to fall back and downward (glossoptosis).

ping-pong ball fracture:

A pediatric greenstick fracture of the skull.

plaque-forming unit:

The number of viral particles capable of forming plaques per a certain volume.

plasma protein fraction:

A blood product that contains 83% albumin and 17% globulins.

plateau pressure:

The average pressure applied to airways and alveoli at the end of inspiration during positive-pressure mechanical ventilation.

platelet count:

A measurement of the number of platelets in the blood, which is useful for assessing a patient’s coagulation status.

pleural friction rub:

The result of an inflammation that causes the pleura to thicken, decreasing the pleural space and allowing the surfaces of the pleura to rub together.

plexus:

A cluster of nerve roots that permits peripheral nerve roots to function as a group.

pneumatosis intestinalis:

Air in the bowel wall as demonstrated by abdominal radiograph.

pneumocephalus:

A condition in which air or gas accumulates within the cranial cavity.

pneumomediastinum:

The collection of air within the mediastinum (the space within the chest that contains the heart, major blood vessels, vagus nerve, trachea, and esophagus; located between the two lungs).

pneumoperitoneum:

The collection of air within the peritoneum (the membrane in the abdomen encasing the liver, spleen, diaphragm, stomach, and transverse colon).

pneumothorax:

An accumulation of gas or fluid in the pleural space that causes the lung to become detached from the chest wall and collapse.

poikilothermia:

Inability to regulate temperature in an extremity due to lack of perfusion, which may result in abnormally cold extremities.

point-of-care testing (POCT):

Testing done outside of a traditional laboratory, usually near where care is being delivered to a patient (ie, at the patient's bedside), with the results of the testing being used for clinical decision making; also called decentralized testing, bedside testing, and ancillary testing.

Poiseuille's law:

The relationship that flow varies directly with any increase in pressure.

polydipsia:

Excessive thirst, resulting in excessive intake of fluid.

polyhydramnios:

An excessive amount of amniotic fluid that may cause preterm labor.

polyphagia:

Excessive desire to eat, resulting in overconsumption of food.

polyuria:

Frequent and plentiful urination.

pons:

Part of the brainstem located between the midbrain and the medulla oblongata; it relays information to and from the brain and spinal cord along fiber tracts.

poor R-wave progression:

An abnormal R-wave pattern; one of the factors that may signify anterior infarction.

portal hypertension:

An increase in vascular resistance through the hepatic portal system. It can cause high venous pressure in the gastric and esophageal veins, leading to varices, among other problems.

positive end-expiratory pressure (PEEP):

The amount of pressure above ambient pressure present in the airway at the end of the respiratory cycle.

positive-pressure ventilators:

Mechanical ventilators that operate using pressure that is greater than the ambient pressure.

positron emission tomography (PET):

A functional imaging modality that uses radiotracers to visualize physiologic changes over time or distinguish various levels of physiologic activity between tissues.

posterior cord syndrome:

Extension injury that produces dysfunction of the dorsal columns, presenting as decreased sensation to light touch, proprioception, and vibration.

postrenal acute kidney injury:

A type of acute kidney injury caused by downstream obstruction of urine flow from the kidneys, with initially intact nephrons; commonly caused by a blockage of the urethra by prostate enlargement, renal calculi, or strictures.

potentiation:

The effect of increasing the potency or effectiveness of a drug or other treatment; it may occur when two medications are administered concurrently.

PR interval:

The interval of time that occupies the space between the beginning of the P wave and the beginning of the QRS complex.

precipitous delivery:

Delivery in less than 3 hours from the onset of regular contractions; may occur with premature labor.

precision:

A measure of how a value is likely to be the same every time a test is performed.

precordial leads:

The chest leads in an electrocardiogram.

preeclampsia:

A condition of late pregnancy that involves onset of hypertension and proteinuria that manifests with headache, visual changes, and swelling of the hands and feet; also called toxemia of pregnancy. It may be classified as occurring with or without severe features.

prefrontal area:

Part of the frontal lobe that provides control of thought, concentration, depth and ability to think abstractly, memory, and autonomic nervous system response, concomitant to emotional change.

preload:

The end-diastolic stretch of the muscle fibers of the ventricle; measured by right atrial pressure or central venous pressure and wedge pressure.

premature:

Underdeveloped; refers to infants born before 36 weeks from the first day of the last menstrual period.

premature prelabor rupture of membranes (PPROM):

A rupture of membranes in a pregnant woman signaled by a gush of fluid or constant fluid leakage; it accounts for as many as 50% of all preterm deliveries.

premotor area:

Part of the frontal lobe that is adjacent to the motor area and helps coordinate certain movements.

prerenal acute kidney injury:

A type of acute kidney injury caused by decreased perfusion of an intact nephron; often reversible if the underlying condition can be found and perfusion can be restored to the kidney.

pressure gradients:

Differences in pressure, which allow for movement of gas into and out of the lung.

pressure ulcer:

A sore on the skin arising from prolonged pressure. Such ulcers are classified into four stages, with stage 4 being the most severe (tissue necrosis and muscle and bone involvement); all stages are painful and susceptible to infection.

pressure ventilator:

A type of positive-pressure ventilator that ends the delivery of the tidal volume based on a predetermined pressure; therefore, the volume may vary.

preterm labor:

Labor occurring before 36 weeks' gestation, leading to early birth.

prevalence:

The total number of cases of a disease within a population, including both old and new cases of the disease.

priapism:

Prolonged, painful erection of the penis; a urologic emergency.

primary aldosteronism:

A type of aldosteronism usually caused by a tumor on a single adrenal gland that overproduces aldosterone; also known as Conn syndrome.

primary amyloidosis:

The most common form of amyloidosis, affecting the heart, kidneys, tongue, nerves, and intestines; the form of amyloid deposited in this disease is classified as apolipoprotein.

primary apnea:

The initial response to asphyxia at birth that responds to stimulation and oxygen therapy; it is characterized by decreased respiratory effort and a slightly decreased heart rate. If not addressed, the infant will progress to secondary apnea.

primary assessment:

A brief assessment of the patient’s condition in which providers quickly identify any acute life threats. This survey follows a stepwise, rapid evaluation of organ systems and anatomy fundamentally necessary for life, often described as the ABCDE (Airway, Breathing, Circulation, Disability, and Exposure) approach.

primary care centers:

Medical centers that offer outpatient, routine family medicine services, including obstetrics and gynecology, geriatric care, and pediatric primary care, and that coordinate patient care with outpatient specialists as appropriate.

primary decontamination:

A form of decontamination that usually occurs at a scene or outside a health care facility or transport vehicle; intended to protect rescuers and health care providers from exposure to a toxic substance during patient care and transport.

primary MODS:

Multiple organ dysfunction syndrome that results from a direct insult such as trauma.

primary spinal cord injury:

Spinal cord injury that occurs at the moment of impact.

procalcitonin:

A peptide precursor of calcitonin used to identify serious bacterial infection.

prodromal:

Referring to the early signs and symptoms that occur before a disease or condition, such as a toxic exposure, fully appears—for example, dizziness before fainting.

prodrome:

Early symptoms indicating the development of disease.

prodrug:

A medication that, once inside the body, becomes metabolized to a physiologically active form.

prolapsed cord:

A delivery presentation in which the umbilical cord passes through the birth canal in advance of the infant.

prophylaxis:

Treatment of disease before it occurs (ie, to prevent the disease).

propofol-related infusion syndrome (PRIS):

A constellation of symptoms, including arrhythmias (bradycardia or tachycardia), metabolic acidosis, hyperkalemia, rhabdomyolysis or creatine phosphokinase elevations, and progressive renal and cardiac failure, associated with use of propofol.

proprioception:

The ability to perceive the position and movement of one’s own body or limbs.

proprioceptive:

Referring to information that comes from receptors located in the skin, muscles, tendons, and joints; this information helps a person know the position of their body.

protected health information (PHI):

Individually identifiable information (eg, name, Social Security number, and date of birth), health information (eg, laboratory results and medical history), and demographic information (eg, address and telephone number) that is protected by HIPAA.

proteinuria:

Protein levels detected in the urine.

prothrombin time (PT):

A value that represents the extrinsic coagulation pathway’s clotting ability by taking into account various clotting factors, fibrinogen, the prothrombin ratio, and the international normalized ratio.

proton pump inhibitors (PPIs):

Medications that reduce gastric acid secretion; they are used to treat gastroesophageal reflux disease and peptic ulcers.

proximal intestinal obstruction:

Obstruction at or above the level of the jejunum.

proximally caused:

A legal term that describes damages that could have reasonably been anticipated before the breach of duty occurred.

pruritic urticarial papules and plaques of pregnancy (PUPPP):

An itchy rash affecting pregnant women; it may be either isolated to one region or systemic.

pruritus:

Itching.

pseudo-Cushing state:

A condition in which a person has higher cortisol levels from a cause other than actual Cushing syndrome—for example, depression, alcoholism, malnutrition, or panic attack.

psychological first aid (PFA):

An evidence-based approach to managing psychological aftereffects in emergency personnel after particularly distressing responses that relies on the concept of human resilience.

ptosis:

Drooping of an eyelid.

pulmonary artery catheter (PAC):

A catheter with a balloon near its tip that is passed through a vein into the right side of the heart, through the right ventricle, and into the pulmonary artery; it records the pressure transmitted back from the left atrium; also called a Swan–Ganz catheter.

pulmonary artery pressure:

The pressure measured in the pulmonary artery, usually displayed with a pressure waveform and digital systolic, diastolic, and mean values.

pulmonary capillary wedge pressure (PCWP):

The mean pressure measured while occluding the pulmonary artery with a balloon-tipped catheter proximal to the site of measurement; it reflects left atrial pressure; also called pulmonary artery wedge pressure or pulmonary artery occlusion pressure.

pulmonary overpressurization syndrome (POPS):

A diving emergency that can occur during ascent and cause pneumothorax, mediastinal and subcutaneous emphysema, alveolar hemorrhage, and the lethal arterial gas embolism; also called burst lung.

pulmonary vascular resistance (PVR):

The resistance or impedance to ejection of the right ventricle of the heart.

pulmonic stenosis:

An acyanotic heart defect caused by obstruction of blood flow from the right ventricle to the pulmonary artery; also called pulmonary stenosis.

pulsatility index (PI):

A measurement of a left ventricular assist device’s pumping power; calculated as follows: Pulsatililty index = (Maximum pump power – Minimum pump power)/Average pump power.

pulse CO-oximetry:

A noninvasive screening and monitoring method for methemoglobinemia and carbon monoxide exposure.

pulse oximetry:

Measurement of arterial oxygen saturation (Spo_2) and the pulse.

pulse pressure:

The difference between the systolic and diastolic blood pressures.

pulsus paradoxus:

A decrease of more than 10 mm Hg in systolic blood pressure during inspiration.

pyelonephritis:

An infection of the kidney, typically the result of an ascending urinary tract infection.

QRS complex:

Deflections in the electrocardiogram produced by ventricular depolarization.

quality assurance and improvement (QA&I) program:

A program that seeks to generate data that are then used to improve the quality of service provided.

quaternary care centers:

Highly specialized tertiary care referral centers that may be dedicated to advancing clinical research in one or more areas of medicine.

quiescent:

A latent state, as occurs with a dormant virus or bacterium, in which an infected patient will exhibit few to no symptoms.

raccoon eyes:

Orbital fractures and hemorrhage into the surrounding tissue; also called periorbital ecchymosis.

radiation:

Emission of heat from an object into surrounding, colder air.

radiography:

basic imaging modality that uses x-ray radiation to generate a two-dimensional image of the internal form of an object.

rapid decompression:

A condition that occurs when a large leak or hole develops in a pressurized aircraft; it can result in hypoxia and injury to people inside the aircraft and catastrophic failure of the aircraft.

rapid sequence intubation (RSI):

The coadministration of both anesthetic agents and neuromuscular blocking agents to produce a state of unconsciousness and paralysis, which in turn allows for tracheal intubation.

reactive airway disease (RAD):

Any condition that causes hyperreactive bronchioles and bronchospasm.

reactive gastritis:

Gastric irritation that results from recurring contact of the mucosa with antagonistic substances such as bile, pancreatic juice, or nonsteroidal anti-inflammatory drugs.

receptor sites:

Specialized proteins on a cell that receive chemical mediator messages.

reciprocal changes:

An electrocardiogram pattern in which a lead shows a pattern that is the opposite of the one shown in the lead located 180° from the other; for example, the electrode over the area of infarction records ST-segment elevation, whereas the electrode over the lead that is 180° away records ST-segment depression.

reckless conduct:

A more serious finding than typical negligence; it involves consciously disregarding the known risks of a course of action; also called gross negligence.

red blood cell (RBC) count:

A measure of the total number of erythrocytes in the blood.

refractory period:

A short period immediately after depolarization in which the myocytes are not yet repolarized and are unable to fire or conduct an impulse.

refractory stage:

The stage of shock characterized by persistently low mean arterial blood pressure despite vasopressor therapy and adequate fluid resuscitation.

relative contraindication:

A condition that makes a particular treatment or procedure somewhat inadvisable but does not completely rule it out.

relative refractory period:

The period in the cell-firing cycle during which it is possible but difficult to restimulate the cell to fire another impulse.

renal perfusion pressure:

The gradient between renal arterial and venous flow. A significant decrease in this pressure results in ischemia.

renal tubular acidosis (RTA):

A form of metabolic acidosis caused by dysfunction of the kidneys or renal system; it produces an inability to excrete hydrogen in the urine and presents without an elevated anion gap.

Replogle tube:

A double-lumen tube used for gastric decompression in infants with gastrointestinal issues. An 8F size is typically used for an infant and is connected to low intermittent wall suction to collect gastric secretions.

repolarization:

A state in which the cell becomes more negative, moving away from equilibrium with the extracellular fluid; it is an active process.

reservoir of infection:

A host that provides a supply of nutrients and an environmental niche that enables long-term microbial survival.

residual volume (RV):

The amount of air remaining in the lungs after the expiratory reserve volume is exhaled.

resilience:

A person’s ability to withstand negative pressure or “bounce back” from difficulties.

resistance:

The amount of force needed to move a gas or fluid through a single capillary tube.

respiration:

In the context of environmental heat loss, the loss of heat as warm air in the lungs is exhaled into the atmosphere and cooler air is inhaled.

respiratory acidosis:

A pathologic condition (blood pH <7.35) resulting from an accumulation of acids in the body owing to a breathing problem or insufficient function of the respiratory system.

respiratory alkalosis:

A pathologic condition (blood pH >7.45) resulting from an accumulation of bases in the body caused by inappropriate tachypnea.

respiratory depression:

A low respiratory rate (<2 breaths/min in adults) for a prolonged period of time; also called hypoventilation.

respiratory failure:

A situation in which the respiratory system fails to meet the body's metabolic needs. If not reversed, it may lead to respiratory or cardiopulmonary arrest.

respiratory insufficiency:

The inability of the respiratory system to keep up with the metabolic demands of the body.

respiratory syncytial virus (RSV):

A labile paramyxovirus that produces a characteristic fusion of human cells in a tissue culture known as the syncytial effect; it can affect both the upper and lower respiratory tracts but is more prevalent with the lower respiratory tract, causing pneumonia and bronchiolitis.

***respondeat superior*:**

The legal concept that an employer is responsible for the acts of its agents.

restrictive diseases:

Diseases that result in difficulty moving air into the lungs, such as occupational lung diseases, idiopathic pulmonary fibrosis, pneumonia, atelectasis, chest wall deformities and injuries, and neuromuscular diseases that affect breathing.

resuscitative endovascular balloon occlusion of the aorta (REBOA):

A surgical procedure in which arterial access is gained through a femoral approach, a balloon catheter is floated into the aorta, and the balloon is inflated to occlude flow; a temporizing measure for refractory hemorrhagic shock, blunt or penetrating abdominal trauma, pelvic fractures with significant hemorrhage, and ruptured abdominal aortic aneurysms, and possibly for outlying hospitals prior to transfer of a trauma patient to a higher-level trauma center.

reticular activating system (RAS):

A diffuse system that extends from the lower brainstem to the cerebral cortex; it controls the sleep-wakefulness cycle, consciousness, the ability to direct attention to a specific task, and the perception of sensory input that might alter behavior.

reticular formation (RF):

A set of neurons that extends from the upper level of the spinal cord; through the medulla, pons, and midbrain; and into the thalamus and cerebral cortex. It has both excitatory and some inhibitory capabilities, and can enhance, suppress, or modify impulse transmission.

retinal detachment:

Separation of the inner layers of the retina from the pigmented epithelium.

revised trauma score:

A trauma scoring system that rates injury severity by comparing the Glasgow Coma Scale score, the systolic blood pressure, and the respiratory rate and assigning a score ranging from 0 to 13 based on these three values; in some cases the parameters are weighted, resulting in a score ranging from 1.0 to 7.8408.

Rh factors:

Antigens found on the cell membrane of red blood cells.

rhabdomyolysis:

The destruction of muscle tissue leading to a release of potassium and myoglobin, which then accumulate in the blood and urine and impair filtration; occurs most often with crush injuries, electrical burns, or large full-thickness burns.

rhonchi:

Rattling vibrations produced as air flows through mucus or around obstruction in the larger airways.

Richmond Agitation–Sedation Scale (RASS):

An evaluation tool used to assess both agitation and sedation.

rickettsial diseases:

Diseases transmitted via tick bite; the three major diseases in this class are Rocky Mountain spotted fever, ehrlichiosis, and anaplasmosis.

right ventricular pressure:

The pressure in the right ventricle, which consists of the systolic, diastolic, and mean pressures; it is important during insertion and use of a pulmonary artery catheter.

right ventricular stroke work index:

A calculation of the contractility of the right ventricle indexed to the patient's body surface area.

rigid stylet:

A hyperangulated intubation stylet used to facilitate endotracheal tube passage when using an hyperangulated blade.

risk-benefit ratio:

An evaluation of the therapeutic benefits of a medication versus the risks associated with that medication's side effects.

root cause analysis (RCA):

A systematic approach to understanding the causes of a serious adverse event and identifying system flaws that can be corrected to prevent future harm.

rotational force:

An injury-producing force in which the head moves around its center of gravity.

rotation-flexion injury:

A spinal cord injury to C1-C2, the only area of the spine that allows for significant rotation, in which rotation with abrupt flexion produces a stable dislocation in the cervical spine. In the thoracolumbar spine, rotation-flexion forces typically cause fracture rather than dislocation.

rotor-wing aircraft:

A transportation mode used to transport critically ill and injured patients in rural settings distances of up to 150 miles (240 km); also called helicopters.

Roux-en-Y:

The most common type of bariatric surgery, in which the size of the stomach is reduced, the small intestines are divided, and the jejunum is connected to a small hole in the stomach pouch; also known as gastric bypass.

rubrospinal tract:

Part of the midbrain that controls the tone of flexor muscles.

rule of nines:

A system that assigns percentages to sections of the body, allowing calculation of the amount of skin surface involved in the burn area.

safety culture:

In an EMS organization, a system of beliefs and practices that includes acknowledging that organizations engage in high-risk activities and determining the importance of consistent safe operations to counteract these activities, supporting a blame-free environment where errors can be reported without fear of punishment, and maintaining organizational commitment to address reported errors and safety concerns.

SAMPLE:

An acronym for the pertinent details of a patient’s history: Signs and symptoms, Allergies, Medications, Pertinent past medical history, Last oral intake, and Events leading up to the illness or injury.

scintigraphy:

An imaging technology that is similar to angiography except that the red blood cells themselves are radiologically labeled to allow greater specificity.

SCIWORA:

Spinal cord injury without radiographic abnormalities.

sclerema:

Hardening of the skin associated with reddening and edema.

scope of practice:

The body of knowledge, skills, and therapies that CCTPs can legally apply in patient care, based on training, certification, medical direction, and applicable law.

secondary aldosteronism:

A type of aldosteronism that occurs as a result of reduced renal blood flow, which stimulates hypersecretion of aldosterone; it can be caused by obstructive renal artery disease, renal vasoconstriction, and edematous disorders.

secondary amyloidosis:

A form of amyloidosis that occurs as a result of another illness, and that primarily affects the kidneys, spleen, liver, and lymph nodes; the form of amyloid deposited in this disease is classified as amyloid A protein.

secondary apnea:

The response if asphyxia at birth continues, which is characterized by a period of gasping respirations, decreasing heart rate, and decreasing blood pressure; it does not respond to stimulation unless resuscitation is initiated immediately.

secondary assessment:

A patient assessment that occurs after completing the primary assessment and identifying and stabilizing immediate life threats and hemodynamic instability. The secondary assessment involves several components, including a detailed head-to-toe examination, a systems-based approach to specific diseases, and a complete evaluation of vital signs.

secondary care centers:

Medical centers that may not only offer primary care within the same facility but also offer outpatient specialties such as cardiology, neurology, nephrology, mental health, endocrinology, or oncology.

secondary decontamination:

A form of decontamination directed at minimizing patient absorption or injury from a toxic substance; it occurs after initial decontamination has occurred outside a health care facility or transport vehicle.

secondary MODS:

Multiple organ dysfunction syndrome that presents a slower, more progressive insult to organs and frequently results from the sepsis cascade.

secondary spinal cord injury:

Spinal cord injury in which multiple factors permit a progression of the primary spinal cord injury; the ensuing cascade of inflammatory responses may result in further deterioration.

sedative-hypnotic syndrome:

A syndrome characterized by lethargy, sedation, hypoventilation, apnea, bradycardia, and hypotension that occurs following exposure to any medication or chemical that can cause central nervous system sedation, lethargy, or coma.

seizure:

A paroxysmal alteration in neurologic function (ie, behavioral and/or autonomic function).

Seldinger technique:

A technique for obtaining vascular or other hollow organ access that uses a hollow-bore needle inserted percutaneously, followed by placement of a soft-tipped guide wire. The needle is removed and a dilator is temporarily placed. The dilator is removed, the desired catheter is placed over the guide wire, and the guide wire is removed. The catheter is then secured. The technique is most commonly used for inserting a central venous line.

semilunar valves:

The valves (aortic and pulmonic) that are the exits from the left and right ventricles into the aorta and the pulmonary artery, respectively.

Sengstaken-Blakemore tube:

A tube with an inflatable balloon at its end that is inserted into the GI tract and inflated to tamponade bleeding.

sensitivity:

In the context of clinical trials, the ability of a certain test to maximize the number of true positives that test positive. In the context of mechanical ventilation, the control that regulates the amount of negative pressure required by the patient to initiate, or trigger, a breath.

sentinel event:

A patient safety event in which an error reaches a patient and results in death, permanent harm, or severe temporary harm such that interventions are required to sustain life.

sepsis:

A condition of life-threatening organ dysfunction caused by a dysregulated host response to infection; or, a complication of infection, in which the entire body mounts an immune response.

septic shock:

A subset of sepsis in which particularly profound circulatory, cellular, and metabolic abnormalities are associated with a greater risk of mortality than occurs with sepsis alone.

sequelae:

Consequence of a previous disease or injury.

serious adverse event (SAE):

A sentinel event.

seroconversion:

Development of antibodies, measured in the serum, in response to an infection or vaccine.

serosa:

A protective layer of connective tissue over most of the alimentary canal; also called the visceral peritoneum.

serotonin syndrome:

An unusual response to serotonin-altering medications causing hyperserotoninergic symptoms.

severe acute respiratory syndrome (SARS):

A highly contagious, potentially life-threatening lower respiratory tract illness that usually starts with flulike symptoms, including fever, headache, and muscle aches, followed within 2 to 7 days by a dry cough and pneumonia.

severe hypothermia:

A condition in which the core body temperature drops to less than 90°F (32.2°C).

shock index:

An evaluation tool used to predict mortality and the need for transfusion in the trauma patient; defined as heart rate divided by systolic blood pressure.

shoulder dystocia:

A condition in which the infant's shoulders are too large to travel through the birth canal without additional clinical maneuvering of the infant.

shunt:

Perfusion without ventilation.

sickle cell anemia:

A disease caused by inheritance of two sets of recessive genes that produce an abnormal hemoglobin protein, known as Hgb S. The red blood cells become deformed (have a sickle shape) and occlude vessels, clot, and cause great pain in patients.

side effects:

Reactions that can manifest as signs or symptoms that are not desired but are expected based on how the medication works.

simulation:

A training technique that allows health care providers to hone their skills in a safe environment without risk of patient harm and to work in teams to practice both procedures and communication skills.

single-chamber demand pacemaker:

A pacemaker with the pacing lead placed in only one chamber of the heart, in which the generator stimulus is inhibited by a signal derived from the heart's depolarization, thus minimizing the risk of pacemaker-induced fibrillation.

sinus tachycardia:

A heart rate that is faster than normal for the patient’s age.

situation, background, assessment, and recommendation (SBAR):

A technique that allows for a brief, yet concise and expected, handoff of information.

Six Sigma:

A disciplined, data-driven approach and methodology for eliminating defects in any process.

sleeve gastrectomy:

A bariatric surgical procedure that is the first part of a biliopancreatic diversion with duodenal switch procedure, in which the structure of the stomach is changed to a tube; also known as vertical sleeve gastrectomy.

slip:

A lapse in concentration that occurs in the face of distractions, fatigue, or stress.

SLUDGEM:

Acronym for symptoms of anticholinesterase inhibitor toxicity: Salivation, Lacrimation, Urination, Diarrhea, Gastroenteritis, Emesis, and Miosis.

somatogravic illusion:

An error in perception that occurs with acceleration, as the otolith organs are displaced rearward, similar to when a person is looking up. This perception of a nose-up altitude may cause the pilot to push the nose of the aircraft down inappropriately at night or in unlit terrain.

sovereign immunity:

A type of immunity often afforded EMS providers that is provided only to governmental entities. This immunity can align with the reckless or willful and wanton requirements, or it can differentiate between ministerial acts (those requiring a specific act given a set of circumstances) and discretionary acts (those in which the provider has some latitude in decision making).

space equivalent zone:

The atmospheric zone that begins at 50,000 feet. In this zone, 100% oxygen is not sufficient to prevent hypoxia without the use of a pressurized aircraft or suit. Unprotected personnel may experience boiling of body fluids at a level above 66,500 feet.

spatial disorientation:

An error in perception that may result from a person's inability to determine their position, altitude, and motion in relation to the surface of the earth or to a significant fixed object during flight.

specialty care transport (SCT):

The interfacility ground transport of a critically ill or injured patient, including provision of medically necessary supplies and services that are beyond the scope of practice of a paramedic; a term used by the Centers for Medicare and Medicaid Services in determining whether transport charges are reimbursable.

specific gravity:

The chemical property of a fluid that relates its density to the density of water.

specificity:

The ability of a certain test to minimize the number of true negatives that test positive.

spinal shock:

The temporary local neurologic condition that occurs immediately after spinal trauma; it is characterized by swelling and edema of the spinal cord and can lead to a physiologic transection, mechanically disrupting all nerve conduction distal to the injury.

Spo_2:

The noninvasive pulse oximetry measurement of oxyhemoglobin saturation by means of a beam of light applied to a superficial capillary bed such as the digits or ear lobe.

spontaneous bacterial peritonitis:

A bacterial infection of ascitic fluid.

sporadic:

A pattern of disease occurrence in which a disease manifests only occasionally.

stagnant hypoxia:

Hypoxia caused by a malfunction of the circulatory system resulting in a decrease in blood flow.

standard geometry blade:

A device used during indirect (video) laryngoscopy that allows the CCTP to visualize the oral cavity on a monitor.

standard precautions:

The use of gloves, mask, goggles, gown, and shoe covers when handling body fluids or tissues of a patient who is not suspected of having a transmissible disease.

status epilepticus:

A life-threatening neurologic disorder in which an individual experiences prolonged (more than 5 minutes) seizure or does not recover from such seizures.

statute of limitations:

The time limit within which negligence cases must be filed; it is typically 2 years but varies from state to state and may be longer if the patient is a minor.

statutes:

Formal laws passed by a legislative body and signed by an executive.

steady state:

A point in drug administration at which the rate of administration (frequency and dose) is equal to the rate of elimination, resulting in a constant plasma medication level.

stepping reflex:

An infant reflex that occurs when the infant is held up in the air and moves the legs up and down as if marching.

stereognosis:

The ability to sense an object’s form through touch.

sterile cockpit:

The time when unnecessary communication that could distract the pilot is banned in the cockpit—usually during takeoffs, landings, and any other critical phase of flight at the discretion of the pilot-in-command.

Stevens-Johnson syndrome:

A milder form of toxic epidermal necrolysis, in which epidermal detachment involves less than 10% of the total body surface area; it causes sloughing of the skin, mucous membranes, and cells lining the respiratory system.

stimulant washout syndrome:

Excessive sleep, hunger, and depression as a result of excessive amphetamine use.

strain pattern:

An electrocardiogram pattern that involves ST-segment changes and flipped, asymmetric T waves associated with right or left ventricular hypertrophy.

stress:

The reaction of the mind or body to a demand for change; it can have either positive or negative effects.

stress-related erosive syndrome:

A condition in which stress-related mucosal disease develops in critically ill patients, such as those with severe head trauma or burns.

stridor:

High-pitched sound representing air moving past fluid or mechanical obstruction within or immediately above the glottic opening.

stroke:

A disruption of blood flow to the brain that results in a neurologic deficit persisting for more than 24 hours.

stroke volume (SV):

The amount of blood ejected by the ventricles during each contraction; it varies between 60 and 100 mL/beat, with the average being 70 mL.

stroke volume index:

A calculation of the contractility of the left ventricle indexed to the patient’s body surface area; equivalent to the left ventricular stroke work index.

ST segment:

The section of the electrocardiogram complex from the end of the QRS complex to the beginning of the T wave, which represents the period of inactivity between ventricular depolarization and repolarization; mechanically, it represents the time that the myocardium is maintaining contraction.

ST-segment elevation myocardial infarction (STEMI):

A myocardial infarction that shows ST-segment elevation on the electrocardiogram; patients with STEMI have a high probability of coronary thrombus occlusion.

subarachnoid hemorrhage (SAH):

Bleeding between the arachnoid mater and the dura mater.

subdermal burn:

A severe, life-threatening burn involving the deep structures of muscle, bone, larger blood vessels, and nerves; also called a fourth-degree burn.

subdural hematoma (SDH):

Bleeding that accumulates between the dura mater and the arachnoid mater.

subdural space:

The dura-arachnoid junction; this potential space may develop into a real one if a blow to the head causes a loss of blood into the cranial meninges.

submucosa:

The layer of connective tissue below the mucosa; it contains blood vessels, lymph, and nerves.

subthalamus:

An area of the cerebrum that is located below the thalamus and is closely related to the basal ganglia in function.

suction event:

An emergency in which tissue occludes the inlet of the pump in a mechanical circulatory support device.

sulci:

Grooves between adjacent gyri.

sulcus sign:

A deep lateral costophrenic angle on a chest radiograph, which is associated with pneumothorax.

summation effect:

The process whereby administration of multiple medications can produce a response that the individual medications alone do not produce.

superficial burn:

A burn involving only the epidermis, producing very red, painful skin; also called a first-degree burn.

superficial partial-thickness burn:

A burn involving the epidermis and part of the dermis, but not the deeper layers of the dermis; also called a second-degree burn.

supine hypotensive syndrome:

Low blood pressure resulting from compression of the inferior vena cava by the weight of the pregnant uterus when the mother is supine.

supraventricular tachycardia (SVT):

An abnormally fast rhythm originating above the ventricles.

surfactant:

A substance formed in the lungs that helps keep the small air sacs or alveoli from collapsing and sticking together; a low level of this substance in a premature infant contributes to respiratory distress syndrome.

Swiss cheese model:

A model in which errors made by people result in consequences related to flawed systems.

sympathomimetics:

Medications that mimic the body’s sympathetic nervous system response (fight-or-flight response); include epinephrine and norepinephrine.

sympathomimetic syndrome:

A syndrome that involves overstimulation of the adrenergic nervous system, resulting in tachycardia, hypertension, agitation, seizures, hyperthermia, dilated pupils, and diaphoresis.

synergism:

An interaction of two or more medications that results in an effect that is greater than the sum of their effects if taken independently.

systemic inflammatory response syndrome (SIRS):

An immune response to an insult that typically leads to hypotension, shock, and worsened tissue function.

systemic vascular resistance (SVR):

The resistance or impedance to ejection of the left ventricle of the heart.

systole:

The contraction phase of the heart cycle in which the ventricles pump blood out of the heart through the aorta and the pulmonary artery into the systemic and pulmonary circulatory systems.

systolic blood pressure (SBP):

Peak pressure in the arterial system, which occurs during ventricular ejection or systole.

T tube:

A T-shaped tube used to drain bile from the gallbladder.

T wave:

The upright, flat, or inverted wave following the QRS complex of the electrocardiogram, representing ventricular repolarization.

tachyphylaxis:

A condition in which the patient rapidly becomes tolerant to a medication.

tachypnea:

An abnormally fast respiratory rate; marked by shallow respirations.

TeamSTEPPS:

Team strategies and tools to enhance performance and patient safety; a program that embraces the principles of crew resource management and teaches tools and methods by which team members can safely raise concerns, challenge orders that are unclear, and if necessary “stop the line.”

tectospinal tract:

Part of the midbrain that controls reflex motor movements in response to visual and auditory stimuli.

temporal lobe:

The lobe of the brain that is located beneath the temporal bone of the cranium; its primary functions relate to hearing, speech, behavior, and memory.

tension pneumothorax:

A pneumothorax in which an intact chest wall allows air that has entered the thoracic space to progressively accumulate, resulting in catastrophic collapse of pulmonary and cardiac structures in the chest.

tentorium cerebelli:

A fold of the dura mater that separates the occipital lobes of the cerebrum from the cerebellum and brainstem, thereby dividing the brain into upper and lower compartments.

term:

Used to describe an infant delivered at 39 to 40 weeks' gestation.

termination of action:

The amount of time after the medication's concentration falls below the minimum effective level until the point at which it is eliminated from the body.

term newborn:

An infant born between 37 and 42 weeks' gestation.

tertiary care centers:

Medical centers that offer highly specialized inpatient medical care, including advanced and complex medical interventions performed by specialty physicians.

testicular torsion:

Twisting of a testicle about the spermatic cord to the point of ischemia.

tetralogy of Fallot (TOF):

A cyanotic heart defect characterized by four anomalies: ventricular septal defect, pulmonary stenosis, overriding aorta, and right ventricular hypertrophy.

thalamus:

The largest portion of the diencephalons. It acts as a relay station for motor and sensory activity; basic neuronal activity; and memory, thought, emotion, and complex behavior.

therapeutic index:

The ratio of a drug's lethal dose for 50% (LD_{50}) of the population to its effective dose for 50% (ED_{50}) of the population; a medication's margin of safety.

thermal burn:

A burn caused by heat, contact with hot objects, ignited liquids, steam, or hot liquids.

thermistor:

The apparatus used for quickly determining very small changes in pulmonary artery temperature.

thermogenesis:

The production of heat in the body.

thermolysis:

The liberation of heat from the body.

thermoregulation:

The process by which the body maintains temperature through a combination of heat gain by metabolic processes and muscular movement and heat loss through respiration, evaporation, conduction, convection, and perspiration.

third spacing:

A loss of fluids from the intravascular space into the tissues caused by an increase in intravascular pressures and/or increased permeability of the cell membranes. Physical stressors of flight such as temperature, vibration, and changes in gravitational force can cause or aggravate this condition; also, an abnormal increase in the amount of fluid that exits the vascular space and moves into other areas (eg, gut wall, subcutaneous tissue); it can lead to dehydration, electrolyte imbalances, and hypovolemia.

thrombocytopenia:

An abnormally low blood platelet count.

thromboelastography (TEG):

A method used to assess the viscoelastic properties of whole blood that combines multiple measurements of platelet function, the coagulation cascade, and their interaction to form clots.

thrombotic stroke:

A condition that occurs when the blood supply to part of the brain is disrupted by a thrombus, or blood clot.

thrombus:

A blood clot.

thrust:

The force exerted by the aircraft engine, which pushes air backward with the objective of causing a reaction of the aircraft in the forward direction.

thyroid storm:

A rare but severe, life-threatening form of thyrotoxicosis that can occur in patients with long-term, untreated hyperthyroidism, but is more commonly precipitated in hyperthyroid patients by an acute physiologic stressor such as a recent surgery, trauma, infection, administration of large doses of iodine, or abrupt discontinuation of thyroid medications.

thyrotoxicosis:

An excess of thyroid hormones resulting in a hypermetabolic crisis, including tachycardia, hyperthermia (sometimes with a body temperature greater than 103.9°F [39.9°C]), coma with agitation, nausea, vomiting, diarrhea, unexplained jaundice, pulmonary edema, and elevated thyroxine level; severe cases are known as thyroid storm.

TICLS:

A mnemonic used to remember the priorities during initial assessment of an infant’s appearance: Tone, Interactiveness, Consolability, Look or gaze, and Speech or cry.

tidal volume (V_t):

The volume of air moved into and out of the lungs with each respiratory cycle.

time-cycled ventilator:

A type of positive-pressure ventilator in which the ventilator ends inspiration after a selected inspiratory time has been achieved.

time of useful consciousness:

The time between a person’s sudden deprivation of oxygen at a given altitude to the point at which deliberate function is lost. With the loss of effective performance during flight, a person is no longer capable of taking proper corrective or protective actions.

timing:

In the context of intra-aortic balloon pump therapy, a method for coordinating the intra-aortic balloon inflation–deflation cycle with the cardiac cycle (inflation during diastole and deflation synchronous with systole).

Title 14 of the Code of Federal Regulations (14 CFR) Part 91:

A guideline established by the Federal Aviation Administration that governs the operation of all aircraft within the United States, including the waters within 3 nautical miles (6 km) of the US coast.

Title 14 of the Code of Federal Regulations (14 CFR) Part 135:

A guideline established by the Federal Aviation Administration that governs the operations of all commuter or on-demand commercial operations.

tocolytics:

A group of medications used to suppress preterm labor.

tolerance:

Physiologic adaptation to the effects of a drug such that increasingly larger doses of the drug are required to achieve the same effect; in immunology, it is the ability to distinguish between self and nonself cells.

TORCH screen:

A set of lab values taken to detect congenital infections, including toxoplasma immunoglobulin G and immunoglobulin M (1:1,024), rubella titers, urine cytomegalovirus titer, viral culture (for herpes), and culture of scrapings from any vesicular lesions.

torsades de pointes:

An undulating sinusoidal rhythm in which the axis of the QRS complexes changes from positive to negative and back in a haphazard manner.

tort:

A wrongful act between people or entities that gives rise to a civil lawsuit.

total anomalous pulmonary venous return:

A condition in which oxygenated blood returns to the right side of the heart, leading to progressive pulmonary edema.

total lung capacity (TLC):

The maximal amount of air that can fill the lungs; the sum of tidal volume, inspiratory reserve volume, expiratory reserve volume, and residual volume.

total parenteral nutrition (TPN):

The IV administration of all necessary nutrients in a patient whose GI tract does not function.

total protein:

The total quantity of protein in a blood sample.

toxic epidermal necrolysis (TEN) syndrome:

A severe skin reaction to certain medications, environmental allergies, and other unknown toxins, in which epidermal detachment is greater than 30%.

toxic shock syndrome:

A condition that results from the release of bacterial toxins into the body, specifically following infection with *Staphylococcus aureus*, *Streptococcus pyogenes*, or *Clostridium sordellii*.

toxidrome:

A group of symptoms, or syndrome, associated with toxicity of a given substance.

tracheal breath sounds:

Breath sounds heard by placing the stethoscope diaphragm over the trachea or over the sternum; also called bronchial breath sounds.

tracheal deviation:

A late sign of a tension pneumothorax in which the trachea is tugged to one side of the neck, usually opposite the side of the pneumothorax.

tracheal tugging:

Downward traction of the trachea toward the thoracic cavity during inspiration.

tracheomalacia:

A weakening or softening of the tracheal cartilage/rings that leads to respiratory disease.

transcranial Doppler (TCD) ultrasonography:

A noninvasive method of assessing the state of intracranial perfusion and monitoring of cerebral blood flow velocity through thinner areas of the skull. It is used in patients following rupture of an intracranial aneurysm to assess for vasospasm, to identify intracranial lesions following a stroke, and to detect cerebral blood flow changes associated with increased ICP.

transfusion reactions:

Reactions resulting from an endogenous or exogenous factor related to transfused blood.

transient ischemic attack (TIA):

A temporary disruption in the blood flow to the brain that lasts less than 24 hours and has temporary side effects.

transient tachypnea of the newborn:

Transient respiratory distress that lasts a few hours in the newborn and occurs secondary to retained fetal lung fluid.

transjugular intrahepatic portosystemic shunt:

The placement of a shunt in the abdomen that bypasses much of the hepatic portal system; it is intended to decrease portal hypertension and its effects.

translational force:

An injury-producing force in which the head’s center of gravity moves along a linear path.

transmission-based precautions:

Specific precautions used when a patient is suspected to have a particular illness.

transposition of the great vessels:

A cyanotic heart defect that results from the aorta receiving blood from the right ventricle while the pulmonary artery leaves the left ventricle.

trauma injury severity score (TRISS):

A scoring system that uses the results of the Injury Severity Score, the revised trauma score, and the patient’s age to calculate the survivability rate; rarely used in the transport setting.

trauma score:

A score ranging from 1 to 16 that takes into account the Glasgow Coma Scale score, respiratory rate, respiratory expansion, systolic blood pressure, and capillary refill and relates to the likelihood of patient survival; not accurate for patients with severe head injuries.

traumatic asphyxia:

A condition resulting from severe, sudden crushing injury to the chest and abdomen, which forces blood backward out of the right side of the heart; engorges the veins of the chest, neck, and head; and gives the chest, neck, and head an extremely cyanotic appearance.

tricuspid atresia:

A cyanotic heart defect that results from an absent or defective tricuspid heart valve, which causes blood flow from the right atrium to the right ventricle to be blocked.

trifascicular block:

The combination of bifascicular block (a right bundle branch block with a block in the left anterior fascicle or left posterior fascicle) that occurs with a first-degree heart block (prolonged PR interval).

triple-lumen catheter:

A type of catheter consisting of three distinct continuous tubes that allow for pressure monitoring, blood sampling, and fluid and drug administration.

troponin:

A key protein involved in muscle contraction that is present in the serum only after cellular necrosis releases the cellular contents of cardiac muscle (such as after myocardial infarction).

tropopause:

The space between the troposphere and the stratosphere. It rises to 60,000 feet at the equator owing to the expansion of heated air masses and sinks to about 30,000 feet at the poles owing to contracting cold air masses.

troposphere:

A portion of the earth’s atmosphere that extends from the surface of the earth to 5 to 10 miles (26,000–52,000 feet) high depending on the relation to the equator and the poles. This layer is characterized by the presence of water vapors, a constant decrease in temperature with increasing altitude, and large-scale vertical currents.

true anaphylaxis:

An anaphylactic reaction that occurs when the allergen binds to immunoglobulin E on the cell membranes of basophils and when mast cells stimulate the release of histamine from the cell.

true fracture:

The most common type of closed skull fracture, in which the depressed segment has contact with the cranial vault.

tumor necrosis factor (TNF):

A protein mediator that is released primarily by macrophages and T lymphocytes, and that helps regulate the immune response.

turbid:

Cloudy or opaque.

two-point discrimination:

A test of sensation discrimination that measures the shortest distance at which the sides of two separate points of a compass or calipers can be distinguished from each other.

type 1 diabetes:

An endocrine disease that usually starts in childhood and requires daily injections of supplemental insulin to control blood glucose; sometimes called juvenile or juvenile-onset diabetes.

type 2 diabetes:

An endocrine disease that usually starts later in life and often can be controlled through diet and oral medications; sometimes called adult-onset diabetes.

Type I spatial disorientation:

A loss of positional awareness in which the pilot is unaware of becoming disoriented.

Type II spatial disorientation:

A loss of positional awareness in which the pilot is initially unaware of spatial disorientation, but senses that something is wrong.

Type III spatial disorientation:

A sudden incapacitating form of loss of positional awareness.

type-and-crossmatch:

The test to determine compatibility between patient serum and donor red blood cells prior to transfusion.

ulcerative colitis:

An inflammation of the rectal mucosal and submucosal tissues.

ultrasonography:

A technique for mapping the echoes produced by high-frequency sound waves transmitted into the body; the denser material reflects waves back to a transducer that produces an image. It is typically used for obstetrics, gynecology, and abdominal diagnostics.

unassisted systole:

Pressure waveform reflecting what would normally occur without intra-aortic balloon pump assistance.

uncal herniation:

The most common type of brain herniation, in which a portion of the temporal lobe is displaced, resulting in compression of cranial nerve III, the midbrain, and the posterior cerebral artery.

uncus:

The medially curved anterior part of the hippocampal gyrus.

unipolar lead:

A lead in which one of the electrodes is placed in the heart and the other lead is placed in an area of zero potential.

unipolar system:

A type of pacemaker system in which contact between the pacemaker itself and the body tissue forms the ground lead for the implantable pulse generator.

universal donors:

Persons who have type O blood.

universal precautions:

The isolation precautions taken when dealing with all patients regardless of their disease status.

universal recipients:

Persons who have type AB blood.

universal time-out:

A planned pause before the beginning of a procedure that improves communication among all personnel in the room; it allows time for everyone to review important aspects of the procedure.

uremia:

The presence of excessive amounts of urea and other waste products in the blood; can lead to altered mental status.

urinalysis:

Laboratory tests performed on a patient’s urine.

$\dot{V}/\dot{Q}$ ratio:

The relationship between alveolar ventilation and alveolar capillary perfusion. The normal value is 0.8.

vacuum caput:

In a newborn, an accumulation of fluid at the site where a vacuum extractor was used to assist in delivering the newborn.

vasopressor:

A medication that causes constriction of blood vessels, thereby causing blood pressure to rise.

VATER syndrome:

A syndrome consisting of multiple birth defects: vertebral anomalies, anal atresia, tracheoesophageal fistula and/or esophageal atresia, and renal and radial anomalies.

Vaughan-Williams classification scheme:

A classification system for antiarrhythmic medications.

vector:

An organism that carries a disease-causing microorganism from one organism to another.

ventilation-perfusion (/) mismatch:

A state of inadequate ventilation, perfusion, or both, in which there is inadequate gas exchange.

ventilator-associated pneumonia (VAP):

A type of hospital-acquired pneumonia that occurs in ventilated patients and that appears more than 48 hours after endotracheal intubation.

ventral:

Toward the abdomen; anterior.

ventricular septal defect (VSD):

An acyanotic heart defect in which blood flows from the left ventricle to the right ventricle through a hole in the septal wall.

vertebral body:

The anterior weight-bearing structure within the spine.

vertex:

A fetal position in which the head is the lowest part of the fetus, resulting in the head presenting first during delivery; the normal delivery presentation.

vertical banded gastroplasty (VBG):

A bariatric surgical procedure that divides the stomach into two parts; also known as stomach stapling.

vertical compression:

Forces transmitted through vertebral bodies and directed either inferiorly through the skull or superiorly through the pelvis or feet (eg, from a direct blow to the parietal region of the skull or rapid deceleration from a fall through the feet, legs, and pelvis).

vesicant:

A substance that causes tissue injury.

vesicular breath sounds:

Softer, muffled sounds in which the expiratory phase is barely audible.

vestibular:

Related to the organs of equilibrium located in the inner ear.

video laryngoscopy:

An orotracheal intubation technique that involves indirect visualization of the vocal cords via a video camera at the distal end of a blade that provides a video feed to a screen.

viremia:

The presence of viruses in the blood.

virion:

The complete viral particle, including DNA or RNA enclosed in a capsid, that is capable of infecting another cell.

virulence:

Physical or biochemical properties of a disease agent that determine its pathogenicity.

virulence factors:

Adaptations of microbes that enable them to penetrate the immune defenses.

viscerocranium:

The bones making up the facial skeleton.

visual flight rules (VFR):

A mode of flight used when weather conditions are good, meaning there is generally very good visibility and minimal cloud cover; the pilot is responsible for maintaining separation from other aircraft.

vital capacity (V_c):

The maximal amount of air that can be exhaled following a maximal inspiration; the sum of tidal volume, inspiratory reserve volume, and expiratory reserve volume; approximately 80% total lung capacity.

voltage:

The force that causes current to flow in a circuit, measured in volts; also called *amplitude* in a pacing system.

volume ventilator:

A type of positive-pressure ventilator in which the breath ends when the predetermined tidal volume is achieved.

voluntary (somatic) nervous system:

The nervous system fibers that connect the structures of the CNS with skeletal muscles and the integument.

volutrauma:

Trauma caused by excessive lung inflation volumes.

volvulus:

A twisting of the intestine onto itself, usually causing strangulation and ischemia.

washed blood products:

Red blood cell or platelet products in which the small amount of noncellular fluid has been replaced, typically with saline.

water intoxication:

A condition in which the normal balance of electrolytes in the body is pushed outside safe limits by the overconsumption of water.

weather decline:

A situation in which an air medical provider is requested, but the pilot and the flight team determine that the weather does not meet established Federal Aviation Administration guidelines and therefore decline to make the flight.

weight:

The downward force due to the weight (gravity) of the aircraft and its load; directly opposed to lift.

well-being:

“A positive outcome that is meaningful for people and for many sectors of society, because it tells us that people perceive that their lives are going well” (Centers for Disease Control and Prevention); a state of being comfortable, healthy, and happy.

Wernicke area:

Part of the temporal lobe that is responsible for comprehension of both written and spoken words.

West Nile virus (WNV):

An arthropod-borne *Flavivirus* that is spread to birds and humans by mosquitoes; it may be characterized by sudden onset of fever with malaise, anorexia, nausea, vomiting, eye pain, headache, myalgia, rash, lymphadenopathy, fatigue, and arthralgias.

wheezes:

A high-pitched musical sound caused by airflow through a narrowed or constricted airway.

white blood cell (WBC) count:

A measure of the total number of leukocytes in the blood.

whole-bowel irrigation (WBI):

A gastric decontamination method that involves the patient drinking or receiving via a nasogastric tube large quantities of a nonabsorbable, electrolyte-balanced liquid that propels stomach and intestinal contents through the digestive system.

wide complex tachycardia:

A cardiac rhythm of greater than 100 beats/min with a QRS duration of 120 ms or greater; it can be of ventricular or supraventricular origin.

willful and wanton:

A more serious finding than typical negligence misconduct; it usually requires an intentional act of misconduct.

Wolff-Parkinson-White (WPW) syndrome:

A syndrome characterized by short PR intervals, delta waves, nonspecific ST-T wave changes, and paroxysmal episodes of tachycardia caused by the presence of an accessory pathway; one of the conditions that produces supraventricular tachycardia via an accessory pathway.

working diagnosis:

An assumed decision on the medical condition of a patient based on the preliminary investigation; assists in the provision of initial treatment and projection of further diagnostic testing requirements.

zeroing:

The process of calibrating a pressure transducer to eliminate extraneous atmospheric and hydrostatic pressures from the data being measured.

zero-order elimination:

A process by which medications or chemicals are eliminated from the body at a constant rate, regardless of plasma concentration.

zone of coagulation:

The center of a burn, which is usually the deepest and most severely affected area.

zone of erythema:

The outermost area of a burn, which represents the least severely burned area; usually an area of first-degree burn.

zone of stasis:

The area found just outside the zone of coagulation, which represents a burned area that is less severely damaged.

zoonosis:

A disease that occurs in animals and can also be transmitted to humans.

The ambulance volante is a two wheeled covered cart, open at the rear, drawn by a single horse. Many soldiers are lying on the ground and some men are tending to them. The silhouette of a fort with large fields, and several soldiers are in the background.

Back to Figure

The important landmarks are as follows. Eleventh century, Crusades: First record of moving injured patients, by Knights of Saint John. 1784: Physicians witness balloon flight demonstrations by the Montgolfier brothers. 1792, French Revolution: Ground transportation first used to evacuate injured soldiers. French surgeon Dominique Jean Larrey produces the ambulance volante or the flying ambulance and creates first official army medical corps. 1862, Civil War: America’s first ambulance service, to become known as the Ambulance Corps, instituted at the Battle of Antietam by surgeon Jonathan Letterman. 1869: America’s first city ambulance service established in New York City by Bellevue Hospital. Ambulances were dispatched via telegraph and staffed first with physicians and later with non-medical staff owing to shortages of physicians. 1870, Prussian Siege of Paris: First documented case of air medical transport; 160 wounded soldiers and civilians transported from the battlefield by hot air balloons. 1899: First motorized ambulance developed in Chicago, traveling up to 16 miles per hour. 1890 to 1910: M. de Mooy, chief of the Dutch

Medical Service, pursues idea of using litters suspended from balloons to transport patients. 1903: Orville Wright flies the first pilot-operated airplane in Kill Devil Hills, N C. 1909: Captain George Groaman of the U S Army Medical Corps builds a plane specifically designed to carry patients. 1914: Igor Sikorsky invents first helicopter to fly for more than a few seconds. 1917: The first successful use of a motorized aircraft occurs with the French Dorand A R two. June 23, 1917: U S Army Ambulance Service established. Train ambulances, steam boat hospitals, and car or trolley ambulances were popular in some cities. 1920: The chief surgeon of the Army proposes modifications to the de Havilland aircraft to accommodate a pilot, medical officer, and two patients. 1930s: Air ambulances specifically designed with multiple engines, heated cabins, and short runway capability. 1944: World War 2, Burma. Wounded patients first transported via helicopter. 1950: First rescue evacuation via helicopter. Patients are carried on skids outside the helicopter. Vietnam War: Larger helicopter, the Bell U H-1 Huey, code named Dustoff, transports personnel and patients inside aircraft. 1958, California: Businessman Bill Mathews uses helicopter to transport patients and deliver medications during emergencies. 1960s: Europeans institute helicopter programs dedicated to patient care and transport. United States conducts projects to study feasibility of using helicopters to transport civilian patients. 1966: Dublin, Ireland. Physicians provide pre-hospital coronary care. Francis Pantridge, M D, used a portable, light-weight, battery-driven defibrillator in the field. 1966: National Institutes of Health and National Academy of Sciences publish Accidental Death and Disability: The Neglected Disease of Modern Society, recommending a system be designed to transport patients via air ambulances. 1969: Maryland purchases a Bell Jet-Ranger helicopter and institutes the nation’s first public service medevac program. 1969: Prehospital defibrillation first used in the United States. Eugene Nagel, M D, instituted the first U S paramedic program. 1972: Denver, C O. First hospital-based air medical transport program established at Saint Anthony’s Hospital.1981: N H T S A publishes Air Ambulance Guidelines, in which Willis Winert, M D, indicated that air ambulances were improperly equipped to handle critical patients, leading the F A A to demand better equipment and specially trained crews. Today: There are more than 100 air medical programs in the United States, each with specially trained flight crews.

Back to Figure

A set of four cheese slices with holes in them, representing safety barriers, are placed in a line. The last three slices are labeled Latent Failures and the slice right in front is labeled Active Failure. The slices from rear to front, are further labeled as follows. Organizational influences, Unsafe supervision, Preconditions for unsafe acts, and Unsafe Acts. A red arrow labeled Failed or absent defenses runs through the holes from rear to front and the arrow head is labeled Impact of error.

Back to Figure

The first step is the Deliberate harm test. If the actions were as intended, were adverse consequences intended? If yes, consult relevant regulatory body. Advise individual to consult Trade Union Representative. Consider: Suspension, Referral to police and disciplinary or regulatory body, and Occupational Health referral. Any system failures identified are to be highlighted. If actions and adverse consequences are not intended, the next step is the Incapacity test as follows. Is there any evidence of ill health or substance abuse? If yes, then does the individual have any known medical condition? If not, consult relevant regulatory body, advise individual to consult Trade Union Representative. Consider: Occupational Health referral. Reasonable adjustment to duties, and Sick leave. The third step is the foresight test as follows. Did the individual depart from agreed protocols or safe procedures? If yes, were the protocols and safe procedures available, workable, intelligible, correct, and in routine use? Is there evidence that the individual took an unacceptable risk? If no, then advise individual to consult Trade Union Representative, consider Corrective training, Improved supervision, Occupational Health referral, Reasonable adjustment to duties. If no, the next step is substitution test as follows. Would another individual coming from the same professional group, possessing comparable qualifications and experience, behave in the same way in similar circumstances? Or were there any deficiencies in training, experience, or supervision, or were there significant mitigating circumstances? If yes, then a system failure review system should be put in place. If no, consult relevant regulatory body, advise individual to consult Trade Union Representative, consider referral to disciplinary or regulatory body, reasonable adjustment to duties, occupational Health referral, and Suspension. At every step, any system failures identified are to be highlighted.

Back to Figure

The sections in the checklist correspond to the following: nursing prior to transport, respiratory therapy involving vented patients prior to transport, nursing respiratory therapy at procedural site, patient description, additional transport safety requirements, and details about the transport after its conclusion.

Back to Figure

The details of the name of the layer, height above the sea level, and the name of the zone are as follows. Troposphere, 10,000 feet, physiologic zone. Tropopause, 50,000 feet, physiologically deficient zone. Stratosphere, lies between 50,000 feet and 31 miles, the physiologically deficient zone. Stratopause, 31 miles, lies above the physiologically deficient zone. Mesosphere, 50 miles, Space equivalent zone. Thermosphere, lies between 120 and 435 miles. Exosphere lies above the thermosphere from 435 miles above the sea level and above the space equivalent zone.

Back to Figure

An inline figure shows a patient lying inside the seat of the airplane. As the altitude increases, the pressure decreases. The O 2 level in the chest of the patient expands as the pressure decreases.

Back to Figure

An inline figure displays a thermometer whose mercury level is dropping down and a patient lying inside the seat of the airplane. As the altitude increases, the temperature and volume decrease.

Back to Figure

An inline figure focuses on the lungs of a patient, where the oxygen level in the arteries is less and the patient’s lung pumps insufficient oxygen molecules.

Back to Figure

An inline figure shows a patient in a lying position and focuses on the lungs of the patient. The alveolar membrane of the lungs, surrounded by a network of capillaries, exhibits decreased diffusion rate. The three labels by the side of the illustration read as follows. Altitude: Decreased atmospheric pressure. C O P D: Decreased alveolar surface area. Pneumonia: Increased membrane thickness.

Back to Figure

An inline figure shows a patient in a lying position and focuses on the alveolar membrane. The alveolar membrane surrounded by a network of capillaries appears thick and forms nitrogen gas bubbles that are transported to the lungs.

Back to Figure

An inline figure displays a thermometer whose mercury level is dropping down and a patient lying inside the seat of the airplane. As the altitude increases, the temperature and pressure decrease.

Back to Figure

An inline figure displays a patient lying inside the seat of the airplane and focuses on the lung of the patient that contains molecules of carbon dioxide and oxygen. The lungs of the patient in the high altitude diffuse more carbon dioxide into the bloodstream than the oxygen molecules.

Back to Figure

The upward force exerted above the stabilizer bar is labeled, lift. The downward force exerted below the landing skids is labeled, weight. The leftward force exerted from the nose of the helicopter is labeled, thrust. The rightward force exerted from the rotor-wing is labeled drag.

Back to Figure

An inline figure shows a patient in a lying position and focuses on the lungs and the arteries of the patient. The patient is unable to respire properly resulting in less flow of oxygen into the lungs and the oxygen released from the lungs is unable to diffuse into the bloodstream.

Back to Figure

The ear is divided into outer, middle, and inner ears. The outer ear has pinna, the visible ear, and an external auditory canal. The middle ear has a tympanic membrane or eardrum, incus, staples, and Eustachian or auditory tube. The external auditory canal from the outer ear extends to connect to the eardrum which is connected perpendicularly to the Eustachian tube. Three bones named, malleus, incus, and stapes lie on the Eustachian tube. Next to the Eustachian tube lies the inner ear that has a network of semicircular canals that are connected to the Eustachian tube. The inner ear comprises semicircular canals, oval window, vestibular nerve, cochlea, cochlear nerve, vestibule, and round window. The cochlea appears like a snail-shaped coil and has a vestibule at the right which has several vestibular nerves. The oval and right windows connect the middle and inner ears. The oval window appears above the stapes of the middle ear. The round window connects the Eustachian tube and the cochlea.

Back to Figure

The monitor of the instrument displays four panels. In the top left panel, the carbon dioxide levels are traced in a waveform and the bottom left panel plots the carbon dioxide level in a graph. The top right and the bottom right panels display the readings, 39 and 100, which are the levels of E T C O 2 and P C O 2, respectively.

Back to Figure

The expressions display the change in emotions with respect to the intensity of pain. The details of the score and the level of pain are as follows. 0, no hurt; w, hurts little bit; 4, hurts little more; 6, hurts even more; 8, hurts whole lot; 10, hurts worst.

Back to Figure

The illustration is labeled with the following parts: pulmonary arteriole, lung alveoli capillaries, and pulmonary venule. The process of gas exchange is illustrated in the following sequence. Capillary to tissue cells. Oxygen and nutrients are diffused from the alveoli and into the blood, while carbon dioxide and waste are diffused from the blood and into the alveoli.

Back to Figure

The horizontal axis, P a O 2, ranges from 0 to 100, in increments of 10. The vertical axis, S a O 2, ranges from 0 to 100, in increments of 10. The approximate data from the graph are as follows. A solid curve rises almost sharply from (27, 0) to (42, 80) and then curves smoothly toward (90, 100).

Back to Figure

At rest, the following muscles are involved: scalenes, pectoralis minor, serratus anterior, external intercostals, and diaphragm. During inhalation, the following mechanics are in play: sternocleidomastoid moves upward, scalenes move upward, pectoralis minor moves upward, sternum moves outward, external intercostals move upward, and diaphragm moves downward. During exhalation, the following mechanics are in play: transversus thoracis, inward movement of internal intercostals, and downward movement of rectus abdominis.

Back to Figure

The volumes and capacities indicated in the graph are as follows. Total lung capacity is 6,000 milliliters. Tidal volume is the amplitude of a normal peak in the graph and equals 500 milliliters. Inspiratory reserve volume is the volume from between the normal peak and the upper limit of the lung capacity and equals 3,100 milliliters. Functional residual capacity is the volume between the normal trough and the lower limit of the lung capacity and equals 2,400 milliliters. Inspiratory capacity is the volume between the normal trough and the upper limit of the lung capacity and equals 3,600 milliliters. For a deep breath, the amplitude of the peak increases, and the depth of the trough increases. Expiratory reserve volume is the volume between the normal trough and the trough corresponding to a deep breath and equals 1,000 milliliters. Vital capacity is the volume between the trough corresponding to a deep breath and the upper limit of the lung capacity and equals 4,000 milliliters. Residual volume is the volume between the trough corresponding to deep breath and the lower limit of the lung capacity and equals 1,200 milliliters.

Back to Figure

The normal breath sounds are as follows. Tracheal: Inspiratory and expiratory sounds are both loud. This is represented by thick sloping bars connected by a thick slanting bar. Bronchial: Inspiratory sounds are shorter than expiratory sounds, and both are loud. This is represented by a thick shorter sloping bar on the left connected to a thick longer sloping bar on the right. Bronchovesicular: Inspiratory and expiratory sounds are about the same, and of medium intensity. This is represented by two connected sloping bars of medium thickness. Vesicular: Inspiratory sounds last longer than expiratory sounds, and both are faint. This is represented by a thin longer sloping bar on the left connected to a thin shorter sloping bar on the right. The slope for bronchovesicular and vesicular are less steep. Text at the bottom reads, The thickness of the bars shows intensity, loudness, of the breath, and slope correlates with pitch, steeper slope, higher pitch.

Back to Figure

Normal breathing is represented by a waveform with a repeating pattern of a peak followed by a trough corresponding to inhalation and exhalation, respectively. Cerebellum. Cheyne-Stokes breathing: The amplitude increases progressively for each peak corresponding to hyperpnea, followed by decreasing amplitude and frequency that gradually leads to a flat portion corresponding to apnea. Brainstem. Central neurogenic hyperventilation: The frequency of the waveform has increased. Apneustic respiration: The peaks of the waveform are wider, with varying widths and a flat portion between them with minor fluctuations. Biot respiration: The waveform is irregular and has an increased frequency, with a repeating pattern of a region of high amplitude and high frequency followed by a region of low amplitude and lesser frequency. Ataxic respiration: The waveform has an irregular pattern with increased frequency and varying amplitudes. Agonal gasps: The waveform has a repeating pattern of a peak followed by a flat region. The amplitude of the peak is higher than normal. Kussmaul: The waveform has a repeating pattern of a peak followed by a trough. The frequency and amplitude have increased in comparison to normal.

Back to Figure

The horizontal axis is labeled time in seconds, and ranges from 0 to 1. The vertical axis is labeled millimeters of mercury, and ranges from 0 to 40. All data are approximate. The line decreases from 16 to 0 in 0.1 seconds, remains constant till 0.3 seconds, then increases to 32 at 0.4 seconds, then remains almost constant till 0.8 seconds, then decreases sharply, and then remains constant from 1 second. The point (0.8, 35) is marked in the graph.

Back to Figure

The horizontal axis is labeled time in seconds, and ranges from 0 to 1. The vertical axis is labeled millimeters of mercury, and ranges from 0 to 40. All data are approximate. The line decreases from 16 to 0 in 0.1 seconds, labeled A, remains constant till 0.3 seconds, labeled B, then increases to 32 at 0.4 seconds, labeled C, then remains almost constant till 0.8 seconds, labeled D, then decreases sharply till 0.9 seconds, labeled E, and then remains constant from 1 second.

Back to Figure

The horizontal axis is labeled time. The vertical axis is labeled C O 2 in millimeters of mercury, and ranges from 0 to 50. All data are approximate. The line depicts a repeating pattern with a baseline line followed by a rise to a plateau followed by a fall to the baseline, with progressively increasing values of the baseline and a maximum value of 40 in the plateaus.

Back to Figure

The patient is in supine position. One hand presses down on the patient’s forehead firmly, while the other hand uses the index finger and the middle finger under the patient’s chin to tilt the patient’s head backward.

Back to Figure

The patient is in supine position. One hand presses down on the patient’s forehead firmly, while the index finger of the other hand is positioned along the patient’s jawline and the thumb presses down on the lower lip, opening the patient’s mouth.

Back to Figure

The patient is in supine position. The thumbs are positioned on either side of the patient’s cheekbones, pressing down near the corner of the lips. The other fingers are firmly tucked under the jawline on either side.

Back to Figure

Class 1. The mouth is wide open, the tongue is fully out, and the posterior pharynx is fully exposed. Class 2. The mouth is not open as widely, the tongue obscures the posterior pharynx, making it only partially visible. Class 3. The mouth is not open as widely. The base of uvula is exposed, but the posterior pharynx is not visible. Class 4. The mouth is not widely open. Neither the uvula nor the posterior pharynx is visible.

Back to Figure

The oral plane is a vertical line, from the top of the mouth to the base of the neck. The pharyngeal plane is an upward sloping line, from the pharynx to the top of the forehead. The tracheal plane is a downward sloping line, from the trachea to the crown of the head.

Back to Figure

The oral plane is an upward sloping line, from the trachea to the upper lip. The pharyngeal plane is a downward sloping line from the trachea to the forehead. The tracheal plane is a horizontal line, from the trachea to tip of the nose.

Back to Figure

Difficult airway predicted. Question 1. Forced to act? If yes to Question 1, give R S I drugs. Question 2. One best attempt? If yes to Question 2, P I M. If no to Question 2, Go to the failed airway algorithm. If no to Question 1, ask Question 3. Question 3. Failure to maintain oxygenation. If yes, to Question 3, go to the failed airway algorithm. If no to Question 3, ask Question 4. Question 4. B M V or E G D predicted to be successful? If yes to Question 4, ask Question 5. Question 5. Intubation predicted to be successful? If yes to Question 5, R S I with double setup. Go to main emergency airway management algorithm. If no to Question 4 or Question 5, ask Question 6. Question 6. Awake technique successful? If yes to Question 6, postintubation management or R S I. If no to Question 6, I L M A, flexible endoscopy, video laryngoscopy, cricothyrotomy, and B N T I. An alternative to Question 1 is to call for assistance.

Back to Figure

Failed airway criteria. Question 1. Failure to maintain oxygenation? If yes to Question 1, extraglottic device may be attempted. Circothyrotomy. If contraindicated or if no to Question 1, choose one of: flexible or rigid endoscopy, video laryngoscopy, extraglottic device, cricothyrotomy, or optical device. Question 2. Cuffed E T T placed? If yes to Question

2, postintubation management. If no to Question 2, arrange for definitive airway management.

Back to Figure

Two illustrations show a human torso in a lateral view and a vacuum cleaner. The mouth, nose, nasal cavity, wind pipe, ribcage, lungs, and diaphragm are highlighted in the illustration of the torso. In illustration A, air moves into the mouth and nose and through the nasal cavity and wind pipe to the lungs. The ribcage moves outward and downward. The diaphragm moves downward. The lungs expand. This action is similar to a vacuum cleaner’s suction action. In illustration B, the diaphragm moves upward, the ribcage moves upward and inward. The lungs contract to expel air outward to the nasal cavity via the windpipe. This action is similar to the action of a vacuum cleaner pushing air outside.

Back to Figure

Two illustrations show a human torso in a lateral view with the mouth cavity, nasal cavity, wind pipe, ribcage, lungs, and diaphragm highlighted. A bag-mask device is placed in the mouth. In the illustration titled ventilation, pressure is applied to the bag mask. Air moves into the mouth and nose and through the nasal cavity and wind pipe to the lungs. The ribcage moves downward and outward. The lungs expand and the diaphragm moves downward. In the illustration titled exhalation, the diaphragm moves upward, and the lungs contract. The ribcage moves upward and inward, pushing the air out via the wind pipe to the nose and mouth. The bag-mask device in the mouth expands.

Back to Figure

The horizontal axis plots volume in milliliters and the vertical axis plots flow in liters per minute. The inspiration curve starts at the intersection of the two axes and slopes upward to half of the positive horizontal axis and below half of the positive vertical axis. From here, the curve slopes down to the end of the positive horizontal axis. The expiration curve starts from the point where the inspiration curve ends and slopes downward to the end of the negative vertical axis and near the end of the positive horizontal axis. From this point, the curve slopes upward to end at one-fourth of the negative vertical axis. A dotted line is drawn from the expiration curve to the point of intersection of the two axes. The vertical distance from the end of the expiration curve to the start of the inspiration curve is labeled Air trapping. All data are approximate.

Back to Figure

The horizontal axis ranges from 0 to 30 in increments of 15. The vertical axis ranges from 0 to 500 in increments of 250. The graph has two curves that intersect at the start and end. The first curve starts at the origin and gradually slopes upward to 15 pressure and 150 volume. From here, the curve slopes upward to 20 pressure and 500 volume. The curve then slopes up to 30 pressure and 550 volume. The second curve starts at the origin and slopes up to 10 pressure and 500 volume. From here, the curve slopes to 30 pressure and 550 volume. The region between the two curves near the end is shaded and labeled beaking. All data in the graph are approximate.

Back to Figure

Text reads, Inclusion Criteria: Acute Onset of: 1. P a o 2 over F i o 2 less than or equal to 300, corrected for altitude. 2. Bilateral infiltrates consistent with pulmonary edema. 3. No clinical evidence of left atrial hypertension. Part 1: Ventilator Setup and Adjustment. 1. Calculate predicted body weight, P B W. Males: 50 plus 2.3, height in inches minus 60. Females: 50 plus 2.3, height in inches minus 60. 2. Select ventilator mode. 3. Set ventilator to achieve initial tidal volume, V subscript T, equals 8 milliliters per kilogram P B W. 4. Reduce V subscript T by 1 milliliter per kilogram at intervals less than or equal to 2 hours until V subscript T equals 6 milliliter per kilogram P B W. 5. Set initial rate to approximate baseline minute ventilation, not greater than 35 beats per min. 6. Adjust V subscript T and respiratory rate, R R, to achieve p H and plateau pressure, P p l a t, goals, as follows: Oxygenation Goal: P a o 2 of 55 to 80 millimeters of mercury or S p o 2 of 88 percent to 95 percent. Use a minimum positive end-expiratory pressure, P E E P, of 5 centimeters H 2 O. Consider use of incremental F i o 2 forward slash P E E

P combinations such as shown below, not required, to achieve goal. The data from the following tables are presented in the format, F i O 2: P E E P. Lower P E E P forward slash higher F i O 2. 0.3: 5. 0.4: 5. 0.4: 8. 0.5: 8. 0.5: 10. 0.6: 10. 0.7: 10. 0.7: 12. 0.7: 14. 0.8: 14. 0.9: 14. 0.9: 16. 0.9: 18. 1.0: 18 to 24. Higher P E E P forward slash lower F i O 2. 0.3: 5. 0.3: 8. 0.3: 10. 0.3: 12. 0.3: 14. 0.4: 14. 0.4: 16. 0.5: 16. 0.5: 18. 0.5 to 0.8: 20. 0.8: 22. 0.9: 22. 1.0: 22. 1.0: 24. P p l a t Goal: less than or equal to 30 centimeters H 2 O. Check P p l a t, 0.5-second inspiratory pause, at least every 4 hours and after each change in P E E P or V subscript T. If P p l a t greater than 30 centimeters H 2 O: Decrease V subscript T by 1-milliliter per Kilogram steps, minimum equals 4 milliliters per Kilogram. If P p l a t less than 25 centimeters H 2 O and V subscript T less than 6 milliliter per Kilogram: Increase V subscript T by 1 milliliter per Kilogram until P p l a t greater than 25 cm H 2 O or V subscript T less than 6 milliliter per Kilogram. If P p l a t less than 30 centimeters H 2 O and breath stacking or dyssynchrony occurs: May increase V subscript T in 1-milliliter per Kilogram increments to 7 or 8 milliliter per Kilogram if P p l a t remains less than 30 centimeters H 2 O. p H Goal: 7.30 to 7.45. Acidosis, p H plus 7.30, management: If p H 7.15 to 7.30: Increase R R until p H greater than 7.30 or P a c o 2 less than 25 millimeters of mercury, maximum set R R equal to 35 breaths per minute. If p H plus 7.15: Increase R R to 35 breaths per minute. If p H remains less than 7.15, V subscript T may be increased in 1-milliliter per Kilogram steps until p H greater than 7.15, P p l a t target of 30 may be exceeded. May give sodium bicarbonate. Alkalosis, pH equals 7.45, management: Decrease ventilatory rate, if possible. I to E Ratio Goal: Recommend that duration of inspiration be less than duration of expiration. Part 2: Weaning. A. Conduct a spontaneous breathing trial daily when: 1. F i O 2 less than or equal to 0.40 and P E E P less than or equal to 8 centimeters H 2 O or F i o 2 less than 0.50 and P E E P less than 5 centimeters H 2 O. 2. P E E P and F i O 2 are the same or lower than values of previous day. 3. Patient has acceptable spontaneous breathing efforts. May decrease ventilatory rate by 50 percent for 5 minutes to detect effort. 4. Systolic blood pressure greater than or equal to 90 millimeters of mercury without vasopressor support. 5. No neuromuscular blocking agents or blockade. B. Spontaneous breathing trial: If all above criteria are met and subject has been in the study for at least 12 hours, initiate a trial of up to 120 minutes of spontaneous breathing with F i o 2 less than 0.5 and P E E P less than 5 centimeters H 2 O: 1. Place on T-piece, tracheostomy collar, or continuous positive airway pressure, C P A P, less than or equal to 5 centimeters H 2 O with pressure support less than 5 centimeters H 2 O. 2. Assess for tolerance as below for up to 2 hours. a. S p o 2 greater than or equal to 90 percent and or P a o 2 greater than or equal to 60 millimeters of mercury. b. Spontaneous V subscript T greater than or equal to 4 milliliters per Kilogram P B W. c. R R less than or equal to 35 breaths per minute. d. p H greater than or equal to 7.3. e. No respiratory distress,

distress equals 2 or more. Heart rate greater than 120 percent of baseline. Marked accessory muscle use. Abdominal paradox. Diaphoresis. Marked dyspnea. 3. If tolerated for at least 30 minutes, consider extubation. 4. If not tolerated, resume pre-weaning settings. Definition of unassisted breathing, different from the spontaneous breathing criteria, as pressure support is not allowed. 1. Extubated with face mask, nasal prong oxygen, or room air, or. 2. T-tube breathing, or. 3. Tracheostomy mask breathing, or. 4. C P A P less than or equal to 5 cm H 2 O without pressure support or intermittent mandatory ventilation assistance.

Back to Figure

Values on the display unit read 23 P peak centimeters H 2 O, 5.9 exp Min Volume liters per minute, 455 V T E milliliters, 12 f Total beats per minute. The A P V c m v adults forward slash ped values are 450 milliliters V T, 5 centimeters H 2 O P E E P over C P A P, 25 percent oxygen. Tabs below read Controls and Alarms. Two graphs are displayed. The top graph plots Paw centimeters H 2 O along the vertical axis that ranges from 0 to 40 in increments of 20. The horizontal axis plotting flow in liters per minute ranges from 0 to 14 in increments of 2. The graph has one curve that has alternating square shaped peaks and parallel lines. The square-shaped peaks are labeled Short inspiratory time and the parallel lines are labeled long expiratory time. The horizontal axis of the bottom graph ranges from 0 to 14 in increments of 2. The vertical axis ranges from negative 75 to 75 in increments of 25. The curve has alternating positive peaks, negative peaks, and horizontal lines.

Back to Figure

Values on the display unit read 20 P peak centimeters H 2 O, 4.6 Exp minute volume liters per minute, 321 V T E milliliters, and 13 f Total beats per minute. The A P V c m v adults slash ped values are 20 milliliters V t, O centimeters H 2 O, P E E P over C P A P, 50 percent oxygen. Tabs below read Controls and Alarms. Two graphs are displayed. The top graph plots Paw centimeters H 2 O along the vertical axis that ranges from 0 to 40 in increments of 20. The horizontal axis plotting flow in liters per minute ranges from 0 to 14 in increments of 2. The graph has one curve that has alternating downward peaks and parallel lines. The downward peaks are labeled Short inspiratory time and the parallel lines are labeled long expiratory time. The horizontal axis of the bottom graph ranges from 0 to 14 in increments of 2. The vertical axis ranges from negative 45 to 45 in increments of 15. The curve has alternating positive peaks, negative peaks, and horizontal lines.

Back to Figure

Values on the display unit read 23 P peak centimeters H 2 O, 6.0 exp Min Volume liters per minute, 454 V T E milliliters, 14 f Total beats per minute. The A P V c m v adults forward slash ped values are 450 milliliters V T, 5 centimeters H 2 O P E E P over C P A P, 21 percent oxygen. Tabs below read Controls and Alarms. Two graphs are displayed. The top graph plots Paw centimeters H 2 O along the vertical axis that ranges from 0 to 40 in increments of 20. The horizontal axis plotting flow in liters per minute ranges from 0 to 12 in increments of 2. The graph has one curve that has alternating square shaped peaks and parallel lines. The square-shaped peak is labeled Pressure tracing. The horizontal axis of the bottom graph ranges from 0 to 12 in increments of 2. The vertical axis ranges from negative 75 to 75 in increments of 25. The curve has alternating positive peaks, negative peaks, and horizontal lines. The first negative peak between 2 and 4 on the horizontal axis is labeled Flow tracing. The part of the curve that lies on the horizontal axis between 7 and 9 is labeled Expiratory flow which returns to isometric line prior to next breath.

Back to Figure

The first graph plots the curves for normal condition when Cdyn is greater than 0.75 milliliters per centimeter H 2 O per kilogram percent C 20 is greater than 0.80. The two curves intersect at the start and the end. The two curves together form the shape of a rounded rhombus. The curves start just above the origin and end near the end of the horizontal axis and top of the vertical axis. The second graph plots the curves for Low Compliance when Cdyn is less than 0.75 milliliters per centimeter H 2 O per kilogram. The two curves intersect at the start and the end. The two curves together form the shape of a rounded rhombus. The curves start just above the origin and end near the end of the horizontal axis and half of the vertical axis. The third graph plots the curves for Lung Overdistention when percent C 20 is less than 0.80. The two curves intersect at the start and the end. The two curves start just above the origin. The first curve slopes up to half of the horizontal axis and half of the vertical axis and then continues up to three-fourth of the horizontal axis and top of the vertical axis. The second curve starts above the origin and gradually slopes upward in a downward U-shape. It forms a beak-like structure where it intersects the end of the first curve. The fourth graph plots curves for P E E P below critical opening pressure. The two curves intersect at the start and the end. The first curve slopes to before half of the horizontal axis and one-fourth of the vertical axis. From here, the curve travels almost straight up to half of the horizontal axis and near the top of the vertical axis. The second curve is in the shape of an inverted C. The fifth graph plots curves for High Inspiratory Resistance (Pressure Limited Ventilator) when increasing volume at P I P with a closed loop. The two curves intersect at the start and the end. The two curves start just above the origin. The first curve gradually slopes upward to half of the horizontal axis and half of the vertical axis. From here, it slopes straight up to the top of the vertical axis. The second curve slopes nearly straight up to half of the vertical axis. From here, it slopes rightward to intersect the end of the first curve. The sixth graph plots curves for endotracheal tube leak. The first curve starts just above the origin, slopes upward to half of the horizontal axis and half of the vertical axis. From here, the curve slopes leftward and upward to three-fourth of the vertical axis. The second curve starts below half of the vertical axis and slopes upward and rightward to intersect the end of the first curve. The space between the start of the two curves is labeled LEAK. Text reads Inspiratory volume is greater than expiratory volume (open loop).

Back to Figure

Values on the display unit read 33 P peak centimeters H 2 O, 0.80 exp Min Volume liters per minute, 20 V T E milliliters, 15 f Total beats per minute. The A P V c m v adults slash ped values are 70 milliliters V T, 5 centimeters H 2 O P E E P over C P A P, 21 percent oxygen. Tabs below read Controls and Alarms. Two graphs are displayed. The top graph plots Paw centimeters H 2 O along the vertical axis that ranges from 0 to 40 in increments of 20. The horizontal axis ranges from 0 to 6 in increments of 2. The graph has one curve that has a parallel line from 0 to 1 labeled Pressure tracing. The curve forms a square-shaped peak between 1 and 2 labeled Spike. From here, the curve travels parallel to the horizontal axis up to 5, after which it forms another square-shaped peak. In the bottom graph, the horizontal axis plotting Paw centimeters H 2 O ranges from 0 to 40 in increments of 20. The vertical axis plotting V milliliters ranges from 0 to 50 in increments of 10. The graph has two curves. The first curve starts at 5 on the horizontal axis and slopes upward to 30 on the horizontal axis and 20 on the vertical axis. The second curve starts at 5 on the horizontal axis and 10 on the vertical axis and slopes upward to 30 in the horizontal axis and 20 in the vertical axis. All data in the graph are approximate.

Back to Figure

The left hand is placed on its inner edge, with thumb facing upward and next four fingers together. Two electrodes are fixed on the lower side of the wrist, and two wires are inserted into a small, rectangular Train-of-four device. Text on a small window display reads, T O F, 15 s, 60. Up and down buttons are at the bottom of the device.

Back to Figure

The horizontal axis is labeled Test result and has three vertical dotted lines labeled A, B, and C. A is labeled True negative and 100 percent sensitivity at the maximum. B is labeled Most accurate. C is labeled True positive and 100 percent specificity at the maximum. The vertical axis is labeled Frequency. A curvilinear graph labeled Not disease is plotted through (0, 0), (A, 100 percent sensitivity), cuts across Most accurate, and (true positive, 0). A curvilinear dotted graph labeled Disease is plotted through (True negative, 0), (C, 100 percent specificity), and (true negative, 0).

Back to Figure

On the top is a large dot labeled N a superscript plus, overlapped by a smaller dot labeled C l superscript minus. The overlapping dots are labeled Salt. Below is a small dot labeled C l superscript minus. It is surrounded by five water molecules, each comprising of a large dot overlapped by two smaller dots labeled plus. On the right is a large dot labeled N a superscript plus, surrounded by five water molecules, each comprising of a large dot labeled minus overlapped by two smaller dots labeled plus.

Back to Figure

A panel of slots has two rows and two columns and an angle on the right. The top row has the metabolites, N a, C l, and B U N. The bottom row has K, H C 0 3 superscript minus, and C r. The angle on the center right has Gluc.

Back to Figure

A panel of slots has two rows and two columns and an angle on the right. The top row has the values 140, 103, and 15. The bottom row has the values 4.0, 25, and 95. The angle on the center right has a value 0.9.

Back to Figure

Two inward arrows on either side are connected by a straight line in the middle. Notations are as follows. Left side angle: W B C s. Right side angle: Platelets. Above the center line: H g b. Below the center line: H c t.

Back to Figure

Two inward arrows on either side are connected by a straight line in the middle. Values are as follows. Left side angle: 7.75. Right side angle: 275. Above the center line: 14.0. Below the center line: 42.

Back to Figure

The left end of the band is 0 percent and right end is 100 percent. 45 percent is marked as formed elements and 55 percent is marked as Plasma.

Back to Figure

The left end of the band is 0 percent and right end is 100 percent. 22 percent is marked as formed elements and 88 percent is marked as Plasma.

Back to Figure

The left end of the band is 0 percent and right end is 100 percent. 22 percent is marked as formed elements and 88 percent is marked as Plasma.

Back to Figure

The horizontal and vertical axes correspond to time and T E, respectively. The waveform is flat at the beginning, followed by the transformation into the tapering oblong shape, which is followed by a flat portion. The portion from the beginning point to the point of maximum amplitude is labeled clot formation. The portion from the point of maximum amplitude to the end is labeled thrombolysis. The time from the beginning to a point just before the starting of the oblong shape is labeled R. The time between the points just before and just after the starting of the oblong shape is labeled K. The angle between the initial slope of the oblong-shaped portion and the vertical axis is labeled alpha. The amplitude measured between the vertical axis and lower portion of the waveform at maximum amplitude is labeled M A. The amplitude measured between the vertical axis and upper portion of the oblong shape at a point just before it becomes flat is labeled L Y 30.

Back to Figure

The waveforms are flat at the beginning, followed by the transformation into the tapering oblong shape, which is followed by a flat portion. Anticoagulant factor deficiency: The tapering oblong shape formation is delayed, and the shape is thin. Characteristics. Delayed clot formation: R prolonged, K prolonged, Alpha angle decreased, and M A decreased. Platelet blockers: The tapering oblong shape is thin. Characteristics. Decreased clot strength: R normal, K prolonged, alpha angle normal, and M A decreased. Fibrinolysis: The tapering oblong shape is small and thick. Characteristics. Accelerated clot breakdown: R normal, L Y 30 markedly increased, and M A decreased. Hypercoagulable state: The tapering oblong shape is thick and forms early. Characteristics. Accelerated clot formation:

R decreased, K shortened, alpha angle increased, and M A increased. D I C, early: The tapering oblong shape is thick and forms and ends early. Characteristics. Accelerated clot formation and breakdown: R decreased, K shortened, L Y 30 increased, alpha angle increased, and M A increased. Late: The tapering oblong shape starts late and is small and thin. Characteristics: R prolonged, K prolonged, alpha angle decreased, and M A decreased.

Back to Figure

During glycolysis, glucose with six carbon atoms is broken down into 2 P G A L, which contains three carbon atoms each with the terminal carbon atom attached to phosphorus. During this process, 2 A T P is converted to 2 A D P. 2 P G A L is converted to 2 pyruvate molecules with three carbon atoms. During this process, 2 N A D positive is converted to 2 N A D H, and 4 A D P is converted to 4 A T P. Net: 2 A T P, 2 N A D H, and 2 pyruvate molecules.

Back to Figure

A. Transition reaction: Pyruvate molecule with three carbon atoms converts to acetyl C o A, which contains carbon atoms attached to C o A. In this process, C O 2 is released, and N A D positive is converted to N A D H. B. Krebs cycle: The output of the transition reaction is used to covert 3 N A D positive to 3 N A D H, covert F A D to F A D H 2, release 2 C O 2, and convert A D P to A T P.

Back to Figure

Decreased cardiac output leads to decreased pressure and activation of sympathetic nervous system. The various effects on the different organs are as follows. Blood vessels: Constriction of the Integumentary system, Renal system, and Gastrointestinal tract. Skeletal muscle: Dilation. Coronary arteries: Dilation. Sweat glands: Diaphoresis. Heart: Increased rate and increased stroke volume. Lungs: Increased rate and depth of respiration. Pupils: Dilation.

Back to Figure

The hormonal compensation of various organs is as follows. Kidneys: Decreased renal blood flow leads to Renin production leading to release of aldosterone causing Sodium and water retention. Hypothalamus: Posterior pituitary: Release of antidiuretic hormone, A D H, leads to Sodium and water retention. Anterior Pituitary: Release of adrenocorticotropic hormone leads to release of cortisol causing hyperglycemia. Adrenal medulla: Release of epinephrine and norepinephrine.

Back to Figure

Decreased cardiac output leads to decreased blood flow to the lungs causing increased physiologic dead space, decreased arterial Partial pressure of Oxygen, which in turn stimulates chemoreceptors. This causes Increased rate and depth of respirations, Increased Partial pressure of Carbon dioxide, and therefore increased sympathetic response. This is followed by respiratory alkalosis, Cerebral vasoconstriction, Cerebral ischemia, and decreased level of consciousness.

Back to Figure

Triggering process leads to the Activation of coagulation cascade that causes microclots leading to Ischemia and Hemolysis, depletion of platelets, and bleeding. Microclots also cause Fibrinolysis that leads to bleeding.

Back to Figure

On the left is Normal blood volume depicted by a square labeled Volume and a thin vertical rectangle labeled Space. In the center is Distributive shock with same volume and increased space, and is depicted by a square labeled Volume and a large rectangle labeled Space. On the right is Hypovolemic shock having same space and decreased volume, depicted by two narrow, vertical rectangles labeled Volume and Space.

Back to Figure

T N F, interleukins, and other cytokines disrupt normal inflammatory modulators in S I R S and sepsis, leading to Interleukins and T N F manifesting as edema and tissue hypoperfusion. Then the Neutrophils are activated, and selectin is inhibited, and Neutrophils can no longer adhere to nor cross through the endothelial wall to the affected areas. The Immune response is disrupted and systemic inflammatory response occurs.

Back to Figure

Clavicle, the collar bone which is the curved anterior bone of the shoulder. Pericardium, the membrane that encloses the heart. Sternum, a long flat bone located at the center of the chest. Suprasternal notch, a large dip in between the neck. Manubrium, the handle shaped, uppermost segment of the sternum. Angle of Louis, the sternal angle below manubrium. Xyphoid process, a small cartilaginous extension at the lower end of the sternum. Heart, located behind the left of the breastbone. Lungs, located on either side of the chest. Pleura, the part of membrane lining the thorax and enveloping the lungs. Diaphragm, a sheet of internal skeletal muscle that covers the bottom of the thoracic cavity.

Back to Figure

A wound site is marked at the left lung which is collapsed. The parietal pleura covers the internal surface of the thoracic cavity. The visceral pleura covers the surface of each lung. Air is accumulated in the pleural space between the left lung and the chest cavity. The illustration also locates the other normal lung, the heart, and the diaphragm.

Back to Figure

The neck area is divided into three zones from 1 through 3. Zone 1 is the lowermost part around the clavicle. Zone 2 is in line with the cricoid cartilage that encircles the trachea. Zone 3 lies at the start of the neck area.

Back to Figure

The central nervous system includes the brain and the spinal cord. The peripheral nervous system includes the cranial nerves and the spinal nerves. The cranial nerves are sensory nerves. The spinal nerves are motor nerves. When a hand approaches fire, the sensory nerves sense it and the motor nerves make the hand to remove from the fire. The sympathetic nervous system activates the fight or flight response. The parasympathetic nervous system is responsible for the body’s rest and relax response. The sympathetic and parasympathetic nerves are activated by the autonomic nerves.

Back to Figure

The locations of the bones and their names are as follows. At the top of the skull, parietal bone. Forehead, frontal one. Central and sides of the skull, sphenoid bone. Temples and ears, Temporal bone. Behind the nose, lacrimal bone. Cheek, zygomatic bone. On the breathing passage of the nose, middle and inferior nasal conchae. On the nose, nasal bones. Nasal cavity, ethmoid none. Lower part of the nasal septum, u-shaped vomer bone. Fixed upper jaw, maxillae. Lower jaw, mandible.

Back to Figure

The locations of the bones and their names are as follows. Bone at the midline of the roof of the mouth in the upper jaw, maxilla. Central and sides of the skull, sphenoid bone. Back of the nasal cavity and between the maxilla and the sphenoid bone, palatine bone. Lower part of the nasal septum, u-shaped vomer bone. At the back and lower part of the skull, occipital bone.

Back to Figure

The anterior fossa contains the frontal bone. At the middle of the frontal bone lies the crista galli and cribriform plate. At the middle fossa lies the sphenoid bone and temporal bone. The sphenoid bone is at the center of the skull and covers the optic foramen and sella turcica. The temporal bone has a passage called carotid canal. The posterior fossa has a trapezoid-shaped occipital bone at the center. The occipital bone and the temporal bone form an opening called the jugular foramen, which is located behind the carotid canal. At the center of the occipital bone lies the foramen magnum, which is a large oval-shaped opening.

Back to Figure

The skull covers the brain. The three membranes that are located below the skull and protect the brain include the dura mater followed by arachnoid and pia mater. Cerebrospinal fluid is found within the brain. An inline diagram marks the meninges in the following order. Skull, dura mater, arachnoid, pia mater, and cerebrospinal fluid found within the tissue of the pia mater.

Back to Figure

The brain is covered by two lateral ventricles, at the left and right sides of the cerebrum. The third ventricle is located between the right and left thalamus, and the fourth ventricle is at the back of the pons and upper-half of the medulla oblongata. Foramen of Monro are the channels that connect the lateral ventricles with the third ventricle at the midline of the brain. Each of the ventricles has a network of blood vessels called choroid plexus that produces the cerebrospinal fluid. The cerebral aqueduct is within the brain stem and it connects the third ventricle to the fourth. The foramen of Magendie is an aperture that drains the C S F from the fourth ventricle into the cisterna magna. The foramen of Luschka is an aperture that drains the C S F from the fourth ventricle.

Back to Figure

The frontal lobe at the forebrain is responsible for conscious thought, primary motor area, speech, and smell. The parietal lobe is at the center of the brain, behind the frontal lobe and above the temporal lobe. This is the primary sensory area that is responsible for taste, body awareness, and language. The temporal area located below the parietal love is responsible for hearing and reading. The occipital lobe that forms the posterior brain is responsible for vision.

Back to Figure

The brain is located within the skull. Meninges cover the brain. The cerebrum is the uppermost region of the brain. The corpus callosum is a bundle of nerve fibers that is located within the longitudinal fissure of the brain. The trunk of the brain has the midbrain, the pons, and the medulla. Thalamus is located at the center of the brain and hypothalamus is located behind the thalamus. Reticular activating system is a diffuse network of nerve pathways that are found in the brainstem. The brainstem, located at the center of the brain has the midbrain at the top, the pons at the middle and medulla, a long, stem-like part at the bottom. The oculomotor nerve arises from the midbrain of the brainstem. The trochlear nerve is located posterior to the midbrain. A cerebral aqueduct connects the third and fourth ventricles of the brain. The Sylvian aqueduct is a narrow passage that connects the third and fourth ventricles. The superior colliculi are paired, projected structures in the rostral midbrain. The inferior colliculi are parts of the midbrain. The cerebellum forms the dorsal part of the brain.

The spinal cord is a long, thin, tube-like structure that extends from the medulla oblongata.

Back to Figure

The cerebral cortex is the large uppermost part of the brain. The brain stem has three divisions, midbrain, pons, and medulla, where pons is located between the midbrain and the medulla. The hypothalamus is located at the center of the brain. The medial thalamus is located at the upper part of the lateral wall of the third ventricle. The spinal cord extends from the medulla. Cerebellum is the dorsal part of the brain that is attached to the brainstem.

Back to Figure

Details of the arteries and the organs through which they pass through are as follows. Basilar, base of the skull. Internal carotid, inner side of the neck. Vertebral, the brainstem, cerebellum, and the back regions of the cerebral hemispheres. Subclavian, the upper thorax. Cerebral, the frontal and parietal lobes. External carotid, head and neck. Common carotid, the neck. Brachiocephalic, aortic arch.

Back to Figure

The names of the veins and their location are as follows. Retromandibular, deep facial vein. Internal jugular, largest vein in the neck. External jugular, superficial vein of the neck formed by the union of retromandibular vein and the posterior auricular vein. Internal jugular, base of the skull. Right brachiocephalic, behind the right side of the sternum. Facial, throughout the face. Lingual, the upper, sides, and under surface of the tongue. Superior thyroid, within the thyroid gland in the neck. Superior vena cava, upper chest.

Back to Figure

Cervical, contains seven vertebrae on the neck bones. Thoracic, contains 12 vertebrae on the chest bones. Lumbar, 5 vertebrae on the abdominal backbones. Sacral, contains 5 vertebrae fused at the central bones of the buttock. Coccyx, contains 3 vertebrae at the tail bone.

Back to Figure

The bony arch at the top forms the lateral and posterior positions of the vertebra. Traverse process extends laterally and posteriorly from the vertebral body and articulates with the ribs. A spinous process is centered posteriorly behind the arch point. The spinal cord passes through the rib cage. The lamina connects the transverse and spinous processes. A pair of spinal nerve roots extend from the spinal cord, at the left and right. The vertebral body is below the rib cage. The pedicle connects the vertebral body and the transverse process.

Back to Figure

The spinal cord has a central canal, gray matter, and white matter. The meninges of the brain have the layers, dura mater, arachnoid, and pia mater that are covered by the spinal cord. Dorsal root ganglion is the cluster of neurons within the dorsal root of the spinal cord. The subdural space lies between the dorsal root of the spinal cord and the dura mater. The spinal nerves pass through the spinal cord.

Back to Figure

Cervical plexus, C1 to C 5, innervates the diaphragm. Brachial plexus, C 5 to T 1, controls the upper extremities. Lumbar plexus, L 1 to L 4, supplies the skin and muscles of the abdominal wall, external genitalia, and part of the lower limbs. Sacral plexus, L 4 to S 4, supplies the buttocks, perineum, and most of the lower limbs.

Back to Figure

The dermatomes include trigeminal cranial nerves from V 1 through V3, cervical dermatomes from C 2 through C 8, thoracic nerves from T 1 through T 12, lumbar nerves from L 1 through L 5, and the sacral dermatome, S 1. Trigeminal cranial nerves. V 1 is on the forehead, V 2 is on the upper jaw, and V 3 is on the lower jaw. Cervical dermatomes. C 2 and C 3 dermatomes are located on the upper neck and lower neck, respectively. C 4 is on the shoulder. C 5 is on the upper arm. C 6 is on the radial side of the hand, on the thumb. C 7 is on the middle finger of the hand. C 8 is on the little finger of the hand. Thoracic dermatomes. T 1, on the middle forearm. T 2, extending from the upper forearm to the armpit. T 3 to T 12 are the dermatomes of the thorax and abdomen. T3, anteriorly and posteriorly extends at the level of the lower axilla. T4, anteriorly at the level of the nipple. T5, anteriorly at the level just inferior to the nipple. T6, anteriorly at the level of the sternum. T 7 to T 9, evenly distributed anteriorly between T 6 and T 10 dermatomes. T 10, anteriorly at the level of the umbilicus. T 11, evenly distributed anteriorly between T 10 and T 12 dermatomes. T 12, anteriorly just superior to the pelvic girdle. Lumbar dermatomes. L 1 to L 5 and S 1 are the dermatomes of the lower limbs that are spirally distributed. L 1, anterior to the groin and the pelvic girdle. L 2, anteriorly covers the thigh. L 3, extending medially from the thigh to the leg. L 4, posterior to the knee. L 5, at the lower leg. Sacral dermatome. S 1, at the foot.

Back to Figure

In the first position, the patient lies flat on his back. In the second position, the patient tries to lift his left leg partially, with the help of a C C T P who places one of his hands around the patient's feet and the other hand on the patient's knees.

Back to Figure

The parts are as follows. Hypothalamus, the body temperature control center is located at the center of the brain. Pons, the part of the brain stem that is located inferior to the midbrain and superior to the medulla oblongata. Medulla, which is the cardiovascular system control center, forms the lower part of the brain stem. Medulla and pons function as the respiratory system control center.

Back to Figure

The consecutive processes are as follows. Hypoxemia and cerebral hypoperfusion lead to oxygen deprivation, which further leads to energy failure, membrane pump failure, and intracellular swelling, which results in the accumulation of neurotransmitters such as N a sup positive, C l sup negative, C a sup 2 positive, and H 2 O and elimination of K sup positive. The accumulation of these neurotransmitters results in neuronal excitation which leads to energy failure.

Back to Figure

Intracranial effects lead to hematoma and impaired autoregulation, both leading to an increase in the I C P. The increase in I C P leads to the reduction of cerebral blood flow which leads to metabolic failure, edema, and again to an increase in I C P. This is a cyclic process. Systemic effects are as follows. Blood loss resulting in low B P leads to cerebral blood flow that causes metabolic failure. This leads to metabolic failure which leads to edema. The cyclic process continues. Edema increases the intracranial pressure which leads to a decrease in the cerebral blood flow, leading to metabolic failure and to edema that leads to an increase in the I C P which further results in the reduction of cerebral blood flow. These lead to metabolic failure and edema. This is a cyclic process. Fever and hypernatremia lead to edema. Blocked airway results in inadequate respiratory effort that leads to hypoxia and hypercarbia. This leads to metabolic failure and finally to edema which results in the increase in I C P that leads to reduced cerebral blood flow and metabolic failure. The cyclic process continues.

Back to Figure

The illustration displays the skull, the arachnoid, and the dura mater of the brain. At the left side of the head, a tunneled intraventricular catheter is inserted deep into the middle of the brain and an epidural catheter is inserted into the arachnoid. At the right side of the head, a subarachnoid bolt is attached to the arachnoid and a straight intraventricular catheter is inserted deep into the middle of the brain.

Back to Figure

The principal layers of the skin are the outer epidermis and inner dermis with subcutaneous tissue underneath. The epidermis consists of the pore, germinal layer, and a hair strand that arises from the deep layers and protrudes out. The second layer is the dermis separated from the epidermis by a scalloped margin. The dermis consists of the hair follicle from which hair grows, blood vessels, and sensory nerves around it. The sebaceous gland is a small pouch that opens into the hair strand. A sweat gland is a coiled structure that opens up to the surface of the skin. The subcutaneous tissue consists of a thick pad of subcutaneous fat followed by fascia and a layer of muscle.

Back to Figure

Left. Ventral view: the lines of cleavage in various areas are as follows. Head: multiple parallel curved lines in the center and horizontal lines on the lateral sides. Face: multiple intersecting lines. Neck and thorax: multiple parallel V-shaped lines. Shoulders: multiple radiating lines from the armpit. Arms: multiple parallel vertical lines, inverted v-shaped line in the forearm, horizontal and vertical lines in the palm. Thorax: multiple parallel horizontal lines. Abdomen: multiple parallel v-shaped lines. Thighs and parts below knee: multiple parallel slightly curved vertical lines. Knee and dorsum of foot: multiple parallel horizontal lines. Right. Ventral aspect: the lines of cleavage in various areas are as follows. Head: multiple parallel inverted v-shaped lines. Back shoulder and upper part of arms: multiple parallel horizontal lines. Loin: inverted v-shaped parallel lines. Buttocks and thighs: multiple parallel diagonal lines. Forearm: multiple parallel vertical lines. Dorsum of hand: multiple parallel horizontal lines. Calf area: multiple parallel vertical lines.

Back to Figure

Left. Superficial or first degree: The illustration of the skin with epidermis, dermis, and subcutaneous tissue. Few hair follicles are present. A region of redness is present in the epidermis layer. Center. Partial-thickness or second degree: The illustration of the skin with epidermis, dermis, and subcutaneous tissue. Few hair follicles are present. A region of redness is present in the epidermis and upper part of the dermis layer. Few boils are present in the epidermis layer. Right. The illustration of the skin with epidermis, dermis, and subcutaneous tissue. A region of redness is present involving the entire epidermis and dermis layer. A region of black color is present in the epidermis and involves the dermis layer

Back to Figure

The human body is divided into nine sections and occupies the following percentage of body surface area. Left: each arm: 9, head and neck: 18, each leg: 13.5, anterior trunk: 18, posterior trunk or back: 18, genitalia: 1. Center: Each arm: 9, head and neck: 12, each leg: 16.5, anterior trunk: 18, posterior trunk or back: 18, genitalia: 1. Right: Each arm: 9, head and neck: 9, each leg: 18, anterior trunk: 18, posterior trunk or back: 18, genitalia: 1.

Back to Figure

The dorsal and ventral view of a human body depicting the various sections occupying the body surface area. A table lists the various regions of the body in percentage to calculate their total burn. The regions are as follows. Head, neck, anterior trunk, posterior trunk, right arm, left arm, buttocks, genitalia, right leg, left leg. The percentages for various sections presented in the format. Section: dorsal view, ventral view. Head: A, a; neck: 1, 1; Trunk: 19, 19; right arm: upper arm- 2, forearm- 1 and half, palm- 1 and half; left arm: upper arm- 2, forearm- 1 and half, palm- 1 and half; buttocks: 2 and half each; genitalia: 1; right leg and left leg: thighs- B, B, lower leg- C,C, foot- 1 and three quarters, 1 and three quarters. A table lists the relative percentages of body surface area affected by growth. It has four columns: age in years; A, half of head; B, half of one thigh; C, half of one leg. Row entries are as follows. Row 1: 0; 9 and a half; 2 and three quarters; 2 and a half. Row 2: 1; 6 and a half; 3 and a quarter; 2 and a half. Row 3: 5; 6 and a half; 4; 2 and three quarters. Row 4: 10; 6 and a half; 4; 9. Row 5: 15; 4 and a half; 4 and a half; 3 and one quarter. Row 6: adult; 3 and a half; 4 and three quarters; 3.

Back to Figure

The steps are as follows. Primary assessment involves A B C, intubation, ventilation, vascular access, and resuscitation. Secondary assessment includes head to toe exam and history. Then the patient is examined for burn specific stop injury, which includes estimation of the size of burn based on the rule of nines or Lund Browder chart, palm is equal to 0.5 percent B S A. Then estimate the depth of burn by performing a serial examination of the wound. Then begin fluid resuscitations by using the appropriate formula. Then determine the presence of inhalation injury; if yes, follow inhalation injury guidelines; if no, determine the presence of circumferential burn. If yes, follow emergent escharotomy guidelines; if no, perform an evaluation of specific anatomic areas. If yes, treat; if no, evaluate specific injuries, electrical, abuse, drugs, cold, radiologic, or chemical. If yes, treat; if no, determine whether the injury is the result of abuse. If yes, notify proper authorities; if no, treat.

Back to Figure

Immediate care: stop the burning; address the A B C; take cervical spine precautions. Emergency management: airway and breathing. Administer 100 percent oxygen, keep suction and bag-mask device available to support ventilation, intubate early if an intubation inhalation is suspected, assess for the following, injury in an enclosed space, carbonaceous sputum, soot in the mouth, singed nasal hairs, facial burns, stridor and inability to clear secretions, dyspnea, cough, hypoxia, voice changes, hoarse voice, circumferential neck burns, insert a nasogastric tube for intubated persons and those with greater than 20 percent of body surface area burned. Circulation: insert two large-bore I V catheters, determine fluid resuscitation requirements based on the weight in kilograms and surface area burned, start fluids immediately, filtrate to urine output, lactated Ringers solution is the preferred fluid but normal saline is an acceptable alternative, and insert a foley catheter. Wound care: remove clothing and debris, cover burns with clean and dry sterile gauze or sheets. Obtain patient history: how was the victim burned question mark; related injuries; medical and surgical history; current medications; allergies; drug, alcohol, and tobacco use. Consult burn center: pediatric fluid resuscitation; circumferential neck, chest or extremity injury; dark pink or dark urine not clearing with I V fluids; decreased urine output not responding to I V fluids.

Back to Figure

The following parts in the anatomy are labeled, from the top to the bottom, on the right side: left common carotid artery, left subclavian artery, aortic arch, ascending aorta, aortic valve, left pulmonary arteries, pulmonary veins, left atrium, mitral valve, chordae tendineae, papillary muscle, left ventricle, interventricular septum, endocardium, myocardium, and epicardium. The following parts in the anatomy are labeled, from the top to the bottom, on the left side: superior vena cava, pulmonary arteries, pulmonary veins, right atrium, pulmonary valve, tricuspid valve, right ventricle, and inferior vena cava.

Back to Figure

In illustration A, the following parts of the anatomy are labeled, from the top to the bottom, on the right side: aorta, pulmonary artery, left coronary artery, left atrium, circumflex branch of left coronary artery, anterior descending branch of left coronary artery, and coronary vein. The following parts of the anatomy are labeled, from the top to the bottom, on the left side: superior vena cava, right atrium, right coronary artery in coronary sulcus, and inferior vena cava. In illustration B, the following parts of the anatomy are labeled, from the top to the bottom, on the right side: superior vena cava, right pulmonary artery, pulmonary veins, right atrium, inferior vena cava, right ventricle, posterior descending coronary artery in posterior interventricular groove. The following parts of the anatomy are labeled, from the top to the bottom, on the left side: aorta, left pulmonary artery, pulmonary veins, left atrium, coronary sinus, and left ventricle.

Back to Figure

One cardiac cycle comprises two phases: systole and diastole. Systole phase comprises two sounds: S 1 or lub and S 2 or dub. The S 1 or lub sound is heard at the beginning of the systole phase. The S 2 or dub sound is heard between the systole phase and the diastole phase.

Back to Figure

One cardiac cycle comprises two phases: systole and diastole. Systole phase comprises four sounds: S 1 or lub, S 2 or dub, S 3 or da, and S 4 or bla. All four sounds are heard at the beginning of the systole phase. The S 3 or da sound is the abnormal third heart sound. The S 4 or bla sound is the abnormal fourth heart sound.

Back to Figure

The diagram with the following parts of the anatomy labeled: aortic arch, pulmonary arteries, pulmonary veins, left atrium, left ventricle, descending aorta, inferior vena cava, right ventricle, right atrium, and superior vena cava. Arterial blood from the aortic arch flows to the head and arms. Desaturated blood flows from the pulmonary arteries to the lungs. Oxygenated blood flows from the lungs to the pulmonary veins. Arterial blood flows from the descending aorta to the trunk and legs. Venous blood flows from the trunk and legs to the inferior vena cava. Venous blood flows from the head and shoulders to the superior vena cava.

Back to Figure

The following major arteries are labeled from the top to the bottom: internal carotid, external carotid, common carotid, subclavian, innominate, axillary, pulmonary, ascending aorta, brachial, descending aorta, common iliac, ulnar, radial, palmar arches, digital, deep femoral, superficial femoral, popliteal, anterior tibial, posterior tibial, peroneal, dorsalis pedis, and arcuate. The following major veins are labeled from the top to the bottom: internal jugular, external jugular, innominate, subclavian, axillary, superior vena cava, pulmonary, cephalic, brachial, antecubital, inferior vena cava, common iliac, volar digital, great saphenous, femoral, popliteal, anterior tibial, peroneal, posterior tibial, and dorsal venous arch.

Back to Figure

The following parts of the conduction system are labeled: S A node, A V node, bundle of His, left bundle branch, left posterior fascicle, left anterior fascicle, Purkinje fibers, right bundle branch, and internodal pathways.

Back to Figure

The components are as follows. A curved peak of the P wave, a flat segment between the end of P wave and beginning of the Q R S complex, labeled P R, a dip followed by a peak of the Q R S complex, the flat segment between the end of the Q R S complex and the beginning of the T wave, labeled S T, a wide and curved peak of the T wave, and the flat region between the end of the T wave and the beginning of the P wave with a small curved peak of the U wave in between, labeled T P interval. P R interval is between the beginning of the P wave and the Q R S complex. Q T interval is between the beginning of the Q R S complex and the end of the T wave. The R hyphen R interval is between two Q R S complexes. The P R interval corresponds to the right and left atria of the heart and the Q T interval corresponds to the right and left ventricles of the heart.

Back to Figure

The first illustration has spots marked for the leads which are as follows. R A on the right arm, L A on the left arm, V 1 and V 2 at the fourth intercostal space, V 3 below and left to V 2, V 4 below V 3, at the midclavicular line, V 5 below and right to V 4, R L on the right leg, and L L on the left leg. The second illustration has spots marked as follows. V 5 on the anterior axillary line and V 6 on the midaxillary line.

Back to Figure

A V F passes vertically down, a V L passes diagonally on the right, and a V R passes diagonally on the left. A horizontal plane cuts the heart into an upper and lower part and V 1, V 2, V 3, V 4, V 5, and V 6 pass on this plane. Lead 1 passes horizontally through the heart, lead 2 is diagonally down to the right, and lead 3 is diagonally down to the left.

Back to Figure

Lead 1 connects from the negative end of the right arm, labeled R A, to the positive end of the left arm, labeled L A. Lead 2 connects from negative end of R A to the positive end of the left leg, labeled L L. Lead 3 connects from negative end of L A to the positive end of L L. In the second illustration, lead 1 connects from the negative end of R A to the positive end of L A, lead 2 connects from negative end of R A to positive end of the right leg, labeled R L, and lead 3 connects from negative end of L A to positive end of R L.

Back to Figure

Lead 1 connects from the negative end of R A to the positive end of L A, lead 2 connects from negative end of R A to positive end of the right leg, labeled R L, and lead 3 connects from negative end of L A to positive end of R L.

Back to Figure

There are three horizontal lines above which the complexes are drawn. The lines from top to bottom are marked as plus 5, 0, and minus 5. A positive Q R S deflection has a sharp peak that reads as plus 5. An isoelectric Q R S deflection has a sharp peak followed by a sharp dip. A negative Q R S deflection has a sharp dip that reads as minus 5.

Back to Figure

The first illustration has two spots marked on the front of the thorax. V 6 R is marked at the junction between the anterior axillary line and the fifth intercostal space on the right side and V 5 R is marked at the junction between midclavicular line and the fifth intercostal space on the right side. The second illustration has two spots marked on the side of the thorax. V 6 R is marked on the midaxillary line and V 5 R is marked on the anterior axillary line.

Back to Figure

The first illustration has three spots on the left side. V 8 is on the midscapular line, V 9 is a little right and below to V 8, and V 7 is a little above and left to V 8. The second illustration has two spots marked on the side of the thorax. V 6 is marked on the midaxillary line and V 7 on the posterior axillary line.

Back to Figure

The first rhythm consists of consistent sharp peaks in lead 1, sharp dips in a V R, long and sharp dips in V 1, and normal complexes in V 4. The second rhythm consists of consistent small peaks in lead 2, only Q waves in a V L, long and sharp dips in V 2, and normal complexes in V 5. The third rhythm consists of increasing peaks from lead 3, a V P, V 3, to V 6 and small dips in V 3.

Back to Figure

The first rhythm consists of small Q waves in lead 1, consistent dips of P Q R S complex in a V r, long sharp dips in V 1, and normal R wave progression in V 4. The second rhythm consists of small Q R S complexes and sharp T waves in lead 2, small Q waves in a V L, sharp dips of Q R S complexes in V 2, and small Q waves and normal complexes in V 5. The third rhythm consists of small waves and complexes in lead 3 that progressively increase from a V P, V 3, to V 6, small dips in V 3, and Q waves in V 6.

Back to Figure

The first rhythm consists of small Q waves in lead 1, consistent dips of P Q R S complex in a V r, long sharp dips in V 1, and normal R wave progression in V 4. The second rhythm consists of small Q R S complexes and sharp T waves in lead 2, small Q waves in a V L, sharp dips of Q R S complexes in V 2, and small Q waves and normal complexes in V 5. The third rhythm consists of small waves and complexes in lead 3 that progressively increase from a V P, V 3, to V 6, small dips in V 3, and Q waves in V 6. Lead 1, a V L, V 5, and V 6 are shaded. V 1 and V 2 are shaded. V 4 and V 3 are shaded. Lead 2, lead 3, and a V F are shaded. Different colors are used for shading.

Back to Figure

S A node is 60 to 100 beats per minute, atrial cells are 55 to 60 beats per minute, A V node is 45 to 50 beats per minute, His bundle is 40 to 45 beats per minute, bundle branch is 40 to 45 beats per minute, purkinje cells are 35 to 40 beats per minute, and myocardial cells are 30 to 35 beats per minute.

Back to Figure

There are six spokes in the wheel. The angles marked on the wheel, clockwise from the top, are as follows: negative 90 degrees, negative 60 degrees, negative 30 degrees or a V L, 0 degrees or positive pole of lead 1, positive 30 degrees, positive 60 degrees or 2, positive 90 degrees or a V F, positive 120 degrees or 3, positive 150 degrees, 180 degrees or negative pole of lead 1, negative 150 degrees or a V R, and negative 120 degrees.

Back to Figure

A circle at the center of the image reads, left axis deviation from minus 90 degrees to minus 60 degrees, normal from 0 degrees to plus ninety degrees, and right axis deviation from plus 120 degrees to minus 120 degrees. A V R is present at minus 150 degrees, a V L is present at minus 30 degrees, a V F is present at plus 90 degrees, lead 1 is present at 0 degree, lead 2 is at plus 60 degrees, and lead 3 is at plus 120 degrees. The upper left quadrant, labeled extreme right quadrant, has two arrows pointing down, labeled as lead 1 and a V F. The upper right quadrant, labeled as left quadrant, has an arrow pointing up, lead 1, and an arrow pointing down, a V F. A box, labeled pathologic L A D, has an arrow pointing up, lead 1, and two arrows pointing down, a V F and lead 2. Lower left quadrant, labeled right quadrant, has an arrow pointing down, lead 1, and an arrow pointing up, a V F. Lower right quadrant, labeled normal quadrant, has two arrows pointing up, lead 1 and a V F.

Back to Figure

Text above the waves reads, remember, use your calipers, exclamation mark. 1. Lead 1 has no Q wave and a sharp dip of S wave. a V F has no Q wave and S wave. 2. Lead 1 has no Q wave and a sharp dip of S wave. a V F has a small sharp peak of Q wave, a sharp dip of R wave, and no S wave. 3. Lead 1 has no Q wave and a long sharp dip of S wave. a V F has has a q wave and a smaller S wave. 4. Lead 1 has no Q wave and a long sharp dip of S wave. a V F has a very small Q R S complex. 5. Lead 1 has no Q wave and a small sharp dip of S wave. a V F has no Q wave and a sharp dip of S wave. 6. Lead 1 has a very small Q R S complex. a V F has a small sharp peak of Q wave, a sharp dip of R wave, and no S wave. 7. Lead 1 has a small sharp peak of Q wave, a sharp dip of R wave, and no S wave. a V F has no Q wave and a sharp dip of S wave. 8. Lead 1 has a very small Q R S complex. a V F has no Q wave and a small sharp dip of S wave. 9. Lead 1 has a Q and R wave but no S wave. a V F has a a small R wave and a long S wave. 10. Lead 1 has a small sharp peak of Q wave, a sharp dip of R wave, and no S wave. a V F has a very small Q R S complex.

Back to Figure

There are six spokes in the wheel. The angles marked on the wheel, clockwise from the top, are as follows: negative 90 degrees, negative 60 degrees, negative 30 degrees or a V L, 0 degrees 1, positive 30 degrees, positive 60 degrees or

2, positive 90 degrees or a V F, positive 120 degrees or 3, positive 150 degrees, 180 degrees, negative 150 degrees or a V R, and negative 120 degrees. The section between negative 90 degrees and negative 30 degrees is highlighted in blue and identified as the left axis deviation. The section between negative 25 degrees and positive 100 degrees is highlighted in green and identified as normal. The section between positive 100 degrees and negative 90 degrees is highlighted in orange and identified as the right axis deviation.

Back to Figure

There are six spokes in the wheel. The angles marked on the wheel, clockwise from the top, are as follows: negative 90 degrees, negative 60 degrees, negative 30 degrees or a V L, 0 degrees or positive pole of lead 1 or 1, positive 30 degrees, positive 60 degrees or 2, positive 90 degrees or a V F, positive 120 degrees or 3, positive 150 degrees, 180 degrees or negative pole of lead 1, negative 150 degrees or a V R, and negative 120 degrees. Three double-ended arrows are traced outside the wheel: between a V L and 2, between 1 and a V F, and between 3 and a V R.

Back to Figure

There are six spokes in the wheel. The angles marked on the wheel, clockwise from the top, are as follows: negative 90 degrees with downward Q R S deflection, negative 60 degrees or 3 with downward Q R S deflection, negative 30 degrees or a V L with upward Q R S deflection, 0 degrees or positive pole of lead 1 or 1 with upward Q R S deflection, positive 30 degrees with downward Q R S deflection, positive 60 degrees or 2 with upward Q R S deflection, positive 90 degrees or a V F with upward Q R S deflection, positive 120 degrees or 3 with upward Q R S deflection, positive 150 degrees or a V L with downward Q R S deflection, 180 degrees or negative pole of lead 1 with downward Q R S deflection, negative 150 degrees or a V R with upward Q R S deflection, and negative 120 degrees with downward Q R S deflection.

Back to Figure

The following parts of the conduction system are labeled: S A node, A V node, His, R B B, L B B, L P F, Purkinje, L A F, Purkinje, and internodal pathways. A block is highlighted in the right ventricle.

Back to Figure

The right bundle branch block in the heart forms two different electrocardiograph waves. In V 1, there are two sharp peaks and in lead 1, V 6, there is a sharp peak followed by a sharp dip.

Back to Figure

A table has three rows and four columns. Row 1, column 1 reads, lead 1, slurred S, and has a rhythm with a small dip of the S wave which rises up in a concave up manner. Row 1, column 2 reads, V 1, rabbit ears, and has a rhythm with two consecutive peaks. Row 3, column 4 reads, V 6, slurred S, and has a rhythm with a small dip of the S wave which rises up in a concave up manner.

Back to Figure

A horizontal line dips down and then rises up to a peak which then comes down and continues as a horizontal line. The dip is labeled as q and the peak is labeled as R.

Back to Figure

The first rhythm consists of small P and T waves, Q wave, and a small curved S wave in lead 1, sharp dips of Q wave and dips of P and T waves in a V R, dips of P and T waves in V 1, and long sharp peaks of R waves and dips of S waves in V 4. The second rhythm consists of small P and T waves, Q wave, and a small curved S wave in lead 2, small P, Q, S, and T waves in a V L, minute Q R S complexes in V 2, and long sharp peaks of R waves and dips of S waves in V 5. The third rhythm consists of two small peaks and a sharp dip between them in lead 3, small Q R S complexes in a V F, no Q wave and small R and S wave in V 3, and long sharp peaks of R wave in V 6. The fourth rhythm consists of consecutive small P and T waves, Q wave, and a small curved S wave in lead 2.

Back to Figure

The pacemaker cells are as follows, S A node, internodal pathways, A V node, His, R B B, L B B, has a block, L P F, purkinje, L A F, and purkinje. The block results in two variations of rhythm. In V 1, R wave is minute, S wave is deep and curved, and there is no S T interval. In lead 1, V 6, there is absence of Q wave and a wide R and S wave.

Back to Figure

A table has three rows and four columns. Row 1, column 1 reads, lead 1, and has a rhythm with absence of Q wave and a wide R and S wave. Row 1, column 2 reads, V 1, and has a rhythm with widened and downward Q R S complex. Row 3, column 4 reads, V 6, and has a rhythm with absence of Q wave and a wide R and S wave.

Back to Figure

The first rhythm consists of wide Q R S waves in lead 1, only dips in Q R S complexes in a V R, wide and downward Q R S complexes in V 1, and only dips in Q R S complexes in V 4. The second rhythm consists of irregularities in waves and only dips in Q R S complexes in lead 2, wide Q R S complexes in a V L, wide and downward Q R S complexes in V 2, and small and wide Q R S complexes in V 5. The third rhythm consists of wide and downward Q R S complexes in lead 3, smaller and wide Q R S complexes in a V F, wide and downward Q R S complexes in V 3, and wide Q R S complexes in V 6. The fourth rhythm consists of small consecutive dips of the Q R S complexes in lead 2.

Back to Figure

The following parts of the conduction system are labeled: S A node, A V node, His, R B B, L B B, L P F, Purkinje, L A F, Purkinje, and internodal pathways. A block is highlighted in the left ventricle.

Back to Figure

The first rhythm consists of narrow Q and R waves with absence of S waves in lead 1 and downward waves in a V R. The second rhythm consists of minute Q R S complexes in lead 2 and curved S T intervals and absent S waves in a V L. The third rhythm consists of narrow and downward Q R S complexes and only dips in the Q R S complexes and absence of other waves in a V F.

Back to Figure

The following parts of the conduction system are labeled: S A node, A V node, His, R B B, L B B, L P F, Purkinje, L A F, Purkinje, and internodal pathways. A block is highlighted in the left ventricle.

Back to Figure

The first rhythm consists of small Q R S complexes in lead 1, only dips in Q R S complexes in a V R, small peaks and sharp dips in Q R S complexes in V 1, and absent Q waves in V 4. The second rhythm consists of small Q waves and absent S waves in lead 2, small R and long S waves in a V L, sharp dips of S waves in V 2, and long sharp peaks of R waves in V 5. The third rhythm consists of absent S waves and dips of T waves in lead 3, absent S waves and dips of T waves in a V F, sharp dips of S waves in V 3, and sharp peaks of R waves in V 6. The fourth rhythm consists of small consecutive small Q waves and absent S waves in lead 2.

Back to Figure

A table has three rows and four columns. Row 1, column 1 is divided into two. The first part reads, lead 1, slurred S, L P H, and has a rhythm with a small dip of the S wave which rises up in a concave up manner. The second part reads, L A H, and has a similar but smaller S wave. Row 1, column 3 reads, V 1, rabbit ears, and has a rhythm with two consecutive peaks. Row 2, column 1 reads, lead 2, L A H, and has a rhythm with a small R wave. Row 3, column 1 reads, lead 3, L P H, and has a rhythm with small Q and S waves. Row 3, column 2 is divided into two. The first parts reads, a V F, L P H, and has a rhythm with small Q and S waves and the second part reads, L A H, and has a rhythm with no Q wave and a small R wave. Row 3, column 4 reads, V 6, slurred S, and has a rhythm with a small dip of the S wave which rises up in a concave up manner.

Back to Figure

The first rhythm consists of wide Q R S complexes in lead 1, wide R waves and absent S waves in a V R, longer R waves and absent S waves in V 1, and absent Q waves and long S waves that rise is stepwise manner in V 4. The second rhythm consists of absent Q waves, small R waves, and deep S waves in lead 2, long R waves and small Q and S waves in a V L, two consecutive peaks in Q R S complexes in V 2, and absent Q waves and long S waves that rise is stepwise manner in V 5. The third rhythm consists of long and narrow dips of Q R S complexes in lead 3, smaller dips in Q R S complexes in a V F, two small peaks with a small dip in between them in Q R S complexes in V 3, and absent Q waves and long S waves that rise is stepwise manner in V 6. The fourth rhythm consists of consecutive absence of Q waves, small R waves, and deep S waves in lead 2.

Back to Figure

The first rhythm consists of pointed waves, absent Q waves, small R waves, and wide S waves in lead 1, small Q and R waves and absent S waves in a V R, two peaks in Q R S complexes and wide S waves in V 1, and absent Q waves, sharp R waves, and small and wide S waves in V 4. The second rhythm consists of small R waves and smaller Q and S waves in lead 2, absent Q waves, small R waves, and deep and wide S waves in a V L, absent Q waves and curved S T intervals in V 2, and small Q waves and wide and small S waves in V 5. The third rhythm consists of absent P and S waves in lead 3, small Q and R waves and absent S waves in a V F, absent Q waves, long sharp R waves, and S waves that rise in stepwise manner in V 3, and small Q R S complexes and waves in V 6. The fourth rhythm consists of consecutive wide and small Q R S complexes in lead 2.

Back to Figure

In the first wave, the junction between the Q R S complex and the S T segment is sharp and labeled as J point is sharp. In the second wave, the same junction is curved and labeled as J point is diffuse.

Back to Figure

The first strip consists of consecutive wide peak and a narrow peak, followed by a small dip in lead 2. The second strip consists of consecutive small peak, small dip, smaller peak, and a deep and narrow dip in V 1.

Back to Figure

The first, labeled as any precordial lead more or equal to 45 millimeters, consists of a long and narrow S wave. The second, labeled as a V L more or equal to 11 millimeters, consists of a sharp R wave and no S wave. The third, labeled as lead 1 more or equal to 12 millimeters, consists of a sharp R wave and no S wave. The fourth, labeled as a V F more or equal to 20 millimeters, consists of no Q or S wave and a long and narrow R wave.

Back to Figure

The first strip consists of a small dip, a long and narrow R wave, and no S wave in lead 1, a short and narrow dip in a V R, a small R and a long and narrow S wave in V 1, absence of Q wave, and log and narrow R and S wave in V 4. The second strip consists of a small and narrow R and S wave with absence of Q wave in lead 2, a long and narrow R wave with absence of S wave in a V L, a small R wave and a long and narrow S wave in V 2, and a long and narrow R wave and narrow S wave with absence of Q wave in V 5. The third strip consists of a small R wave and a long and narrow S wave with absence of Q wave in lead 3, a small R wave and a narrow S wave with absence of Q wave in a V F, a small R wave and a long and narrow wave with absence of Q wave in V 3, and a small dip, a long and narrow R wave, and aa small S wave in V 6.

Back to Figure

An enlarged right ventricle produces additional vector. This results in two variations in waves. In V 1, there is absence of Q wave, a long and narrow R wave, and a short S wave. In V 2, there is absence of Q wave, a narrow R wave, and a long and narrow S wave.

Back to Figure

The first strip consists of consecutive peaks that descend into a long narrow dip in V 1 and two small curved peaks and a narrow and long peak, followed by a long and narrow dip in V 4. The second strip consists of wide peaks of P and T waves, small and narrow R waves, and long and narrow S waves in V 2 and downward T waves, absence of Q waves, long and narrow R waves, and small S waves in V 5. The third strip consists of wide peaks of P and T waves, narrow R waves, and long and narrow S waves in V 2 and downward T waves and narrow R waves with absence of Q and S waves in V 6.

Back to Figure

An accessory pathway occurs in the ventricle of the heart which forms impulses through accessory pathway. A normal depolarization wave is present right below this. An E C G wave has a curved P wave that curves up to form the R wave, this is labeled as delta wave. A dotted line below this wave represents the normal Q wave dip that is absent here and is labeled as normal tracing if the delta wave were not present.

Back to Figure

The first rhythm consists of small Q R S complexes with absence of P waves in lead 1, a narrow and long dip and a small and wide dip in a V R, long and narrow dips with absence of other waves in V 1, and long and wide R waves with absence of Q and S waves in V 4. The second rhythm consists of narrow R waves and long and wide T waves with absence of Q and S waves in lead 2, small Q R S complexes in a V L, small R waves, long and narrow S waves, and long and wide T waves in V 2, and very long and narrow R waves with absence of Q and S waves and long and wide T waves in V 5. The third rhythm consists of small and narrow Q R S complexes and long T waves in lead 3, two peaks in Q R S complexes and long T waves in a V F, long and very long and narrow R waves, narrow S waves, and long and wide T waves with absence of Q waves in V 3, and long and narrow R waves and long and wide T waves with absence of Q and S waves in V 6. The fourth rhythm consists of consecutive narrow R waves and wide and long T waves with absence of Q and S waves in lead 2.

Back to Figure

The heart has a shaded part in its wall, labeled as ischemia. The E C G wave has an S T depression and a flipped T wave.

Back to Figure

The wall of the heart has ischemia and injury between it. The E C G wave has S T elevation and a flipped T wave.

Back to Figure

The wall of the heart has ischemia with injury and infarct in the middle. The E C G wave consists of a sharp Q wave, S T elevation, and fipped T wave.

Back to Figure

The heart is connected to electrode A on the right side with a microscope inserted in its wall. Around the microscope, the wall is marked as plus which covered by minus. The wave formed has a Q wave, and S T elevation, and a flipped T. The left side is connected to electrode B and the wave formed has a big R wave, an S T depression, and an upright T.

Back to Figure

The first rhythm consists of absence of Q and S waves in lead 1, labeled as lateral, narrow S waves with absence of R waves and flipped P and T waves in a V R, long and narrow dips in V 1, labeled as septal, and long and narrow R waves and small S waves with absence of Q waves in V 4, labeled as anterior. The second rhythm consists of pointed P and T waves and small R waves with absence of S waves in lead 2, labeled as inferior, only small Q R S waves in a V L, labeled as high lateral, long narrow dips and small R waves in V 2, labeled as septal, and long and narrow R waves and small S waves with absence of Q waves in V 5, labeled as lateral. The third rhythm consists of small peaks and no dips in lead 3, labeled as inferior, pointed P and T waves and small R waves with absence of Q and S waves in a V F , labeled as inferior, narrow R waves and S waves with absence of Q waves in V 3, labeled as anterior, and narrow R waves and small S waves with absence of Q waves in V 6, labeled as lateral. Lead 1, a V L, V 5, and V 6 are shaded in yellow. V 1 and V 2 are shaded in green. V 4 and V 3 are shaded in orange. Lead 2, lead 3, and a V F are shaded in blue.

Back to Figure

There are four columns and three rows. Row 1, column 1 reads, lead 1 and lateral. Row 1, column 2 reads, a V R. Row 1, column 3 reads, V 1 and septal. Row 1, column 4 reads, V 4 and anterior and has a rhythm with a small Q wave, an elevated S T segment, and a flipped T wave. Row 2, column 1 reads, lead 2 and inferior. Row 2, column 2 reads, a V L and high lateral. Row 2, column 3 reads, V 2 and septal. Row 2, column 4 reads, V 5 and lateral. Row 3, column 1 reads, lead 3 and inferior. Row 3, column 2 reads, a V F and inferior. Row 3, column 3 reads, V 3 and anterior, and has a rhythm with a small Q wave, long S wave, a curved and elevated S T segment, and a flipped T wave. Row 3, column 4 reads, V 6 and lateral.

Back to Figure

There are four columns and three rows. Row 1, column 1 reads, lead 1 and lateral. Row 1, column 2 reads, a V R. Row 1, column 3 reads, V 1 and septal, and has a rhythm with R wave, long and narrow S wave, elevated and curved S T segment, and a flipped T wave. Row 1, column 4 reads, V 4 and anterior, and a rhythm with a Q wave, R wave, elevated S T segment, and a flipped T wave. Row 2, column 1 reads, lead 2 and inferior. Row 2, column 2 reads, a V L and high lateral. Row 2, column 3 reads, V 2 and septal, and a rhythm with small R wave, long S wave, elevated and curved S T segment, and flipped T wave. Row 2, column 4 reads, V 5 and lateral. Row 3, column 1 reads, lead 3 and inferior. Row 3, column 2 reads, a V F and inferior. Row 3, column 3 reads, V 3 and anterior, and has a rhythm with small q wave, small R wave, S wave, curved and elevated S T segment, and a flipped T wave. Row 3, column 4 reads, V 6 and lateral.

Back to Figure

The first rhythm consists of R waves with no Q and S waves in lead 1, narrow S waves with no Q and R waves and curved S T segments in a V R, narrow long dips and curved and elevated S T segments in V 1, and narrow R waves with elevated S T segments in V 4. The second rhythm consists of narrow R waves with no Q and S waves and depressed S T segments in lead 2, R waves and T waves with no Q, S, or P waves in a V L, small R waves, long S waves, elevated and curved S T segments and T waves in V 2, and R waves and T waves with no Q, S, or P waves in V 5. The third rhythm consists of only small Q R S complexes in lead 3, small R waves and depressed S T segments in a V L, small Q R S complexes on elevated waves in V 3, R waves, depressed S T segments, and pointed P and T waves in V 6. The fourth rhythm consists of R waves with no Q or S waves and depressed S T segments in lead 2.

Back to Figure

The heart is surrounded by a V R on the upper left side, a V L and lead 1 on the upper right side, and lead 2, a V F, and lead 3 on the lower side. Lead 2, a V F, and lead 3 are all labeled as reciprocal changes. The top view of the heart reveals an infarction in the septum, including the lateral wall. The heart is marked from V 1 to V 6. V 1 and V 2 are shaded in green, V 3 and V 4 in red, and V 5 and V 6 in yellow.

Back to Figure

There are four columns and three rows. Row 1, column 1 reads, lead 1 and lateral, and has a rhythm with small Q wave, elevated and curved S T segment, and flipped T wave. Row 1, column 2 reads, a V R. Row 1, column 3 reads, V 1 and septal, and has a rhythm with no Q wave, small R wave, elevated and curved S T segment, and flipped T wave. Row 1, column 4 reads, V 4 and anterior, and has a rhythm with a small Q wave, an elevated S T segment, and a flipped T wave. Row 2, column 1 reads, lead 2, inferior, reciprocal S T depression. Row 2, column 2 reads, a V L and high lateral, and has a rhythm with small Q wave, elevated and curved S T segment, and flipped T wave. Row 2, column 3 reads, V 2 and septal, and has a rhythm with no Q wave, small R wave, elevated and curved S T segment, and flipped T wave. Row

2, column 4 reads, V 5 and lateral, and has a rhythm with a small Q wave, an elevated S T segment, and a flipped T wave. Row 3, column 1 reads, lead 3, inferior, and reciprocal S T depression. Row 3, column 2 reads, a V F, inferior, and reciprocal S T depression. Row 3, column 3 reads, V 3 and anterior, and has a rhythm with a normal Q R S complex, a curved and elevated S T segment, and a flipped T wave. Row 3, column 4 reads, V 6 and lateral, and has a rhythm with small Q wave, elevated and curved S T segment, and flipped T wave.

Back to Figure

The first rhythm consists of two consecutive peaks in Q R S complexes with no T waves in lead 1, elevated P waves and P R segments, no Q waves, small R waves, and S waves in a V R, no Q waves, inverted P waves, small R waves, and long and wide S waves in V 1, and two consecutive long peaks in Q R S complexes in V 4. The second rhythm consists of small Q R S complexes in lead 2, two consecutive peaks in Q R S complexes with no P or T waves in a V L, elevated Q R S complexes that continue as a long wide peak in V 2, and two consecutive long and wide peaks in Q R S complexes in V 5. The third rhythm consists of flipped Q R S complexes and T waves in lead 3, small Q R S complexes with flipped T waves in a V F, Q waves and two consecutive peaks in Q R S complexes in V 3, two consecutive small peaks in Q R S complexes in V 6. The fourth rhythm consists of small Q R S complexes and normal waves in lead 2. The rhythm curves up and goes down.

Back to Figure

The heart is surrounded by a V R on the upper left side, a V L and lead 1 on the upper right side, which is shaded, and lead 2, a V F, and lead 3 on the lower side, labeled as reciprocal changes. The top view of the heart reveals an infarction in the lateral wall. The heart is marked from V 1 to V 6. V 5 and V 6 are shaded.

Back to Figure

There are four columns and three rows. Row 1, column 1 reads, lead 1 and lateral, and rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 1, column 2 reads, a V R. Row 1, column 3 reads, V 1 and septal. Row 1, column 4 reads, V 4 and anterior. Row 2, column 1 reads, lead 2, inferior, and reciprocal S T depression. Row 2, column 2 reads, a V L and high lateral, and rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 2, column 3 reads, V 2 and septal. Row 2, column 4 reads, V 5 and lateral, and rhythm with Q wave, elevated S T segment, and flipped T wave. Row 3, column 1 reads, lead 3, inferior, and reciprocal S T depression. Row 3, column 2 reads, a V F, inferior, and reciprocal S T depression. Row 3, column 3 reads, V 3 and anterior. Row 3, column 4 reads, V

6 and lateral, and rhythm with Q wave, elevated and curved S T segment, and flipped T wave.

Back to Figure

The first rhythm consists of long R waves and flipped T waves in lead 1, two dips, one small and one long and narrow in a V R, flipped P waves, small R waves, and long and narrow S waves in V 1, and no Q waves, long and narrow R waves, S waves, and flipped T waves in V 4. The second rhythm consists of wide R waves and no Q or S waves in lead 2, Q waves, small R waves, elevated S T segments, and flipped T waves in a V L, small R waves, long and narrow S waves, and elevated S T segments in V 2, and long and narrow R waves with absence of Q and S waves in V 5. The third rhythm consists of small Q R S complexes with elevated T P intervals in lead 3, small R waves with absence of Q and S waves in a V F, long and narrow S waves and small R waves in V 3, long and narrow R waves and flipped T waves in V 6. The fourth rhythm consists of wide R waves with absence of Q and S waves in lead 2.

Back to Figure

The heart with an infarct in its lower wall, is surrounded by a V R on the upper left side, a V L and lead 1 on the upper right side, labeled as reciprocal changes, and lead 2, a V F, and lead 3 on the lower side, which is shaded.

Back to Figure

There are four columns and three rows. Row 1, column 1 reads, lead 1, lateral, and reciprocal S T depression. Row 1, column 2 reads, a V R. Row 1, column 3 reads, V 1 and septal. Row 1, column 4 reads, V 4 and anterior. Row 2, column 1 reads, lead 2 and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 2, column 2 reads, a V L, high lateral, and reciprocal S T depression. Row 2, column 3 reads, V 2 and septal. Row 2, column 4 reads, V 5 and lateral. Row 3, column 1 reads, lead 3 and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 3, column 2 reads, a V F and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 3, column 3 reads, V 3 and anterior. Row 3, column 4 reads, V 6 and lateral.

Back to Figure

The first rhythm consists of absence of Q waves in lead 1, flipped P and T waves and long S waves in a V R, S waves with absence of Q and R waves in V 1, and absence of Q waves in V 4. The second rhythm consists of two peaks in Q R S complexes in lead 2, sudden rise in R wave and wide S wave in a V L, long and narrow S waves, small R waves, and absence of Q waves in V 2, and normal Q R S complexes with sudden increase of S wave in V 5. The third rhythm consists of long Q waves, R waves, and absence of S waves in lead 3, small Q R S complexes with absence of S waves and sudden increase in length of Q wave and width of R wave in a V F, R waves, long S waves with absence of Q waves in V 3, and R waves, small S waves with absence of Q waves in V 6. The fourth rhythm consists of two consecutive small and wide waves in the Q R S complexes and a sudden narrow dip in lead 2.

Back to Figure

The heart is surrounded by a V R on the upper left side, a V L and lead 1 on the upper right side, shaded in yellow, and lead 2, a V F, and lead 3 on the lower side, shaded in blue. Text reads, these leads will be affected if the high lateral wall is also involved. The top view of the heart reveals an infarction in the inferolateral wall. The heart is marked from V 1 to V 6. V 5 and V 6 are shaded in yellow.

Back to Figure

There are four columns and three rows. Row 1, column 1 reads, lead 1, lateral, and reciprocal S T depression. Row 1, column 2 reads, a V R. Row 1, column 3 reads, V 1 and septal. Row 1, column 4 reads, V 4 and anterior. Row 2, column 1 reads, lead 2 and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 2, column 2 reads, a V L, high lateral, and reciprocal S T depression. Row 2, column 3 reads, V 2 and septal. Row 2, column 4 reads, V 5 and lateral, and has a rhythm with Q wave, elevated S T segment, and flipped T wave. Row 3, column 1 reads, lead 3 and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 3, column 2 reads, a V F and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 3, column 3 reads, V 3 and anterior. Row 3, column 4 reads, V 6 and lateral, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave.

Back to Figure

The first rhythm consists of long and narrow R waves and wide S waves in lead 1, flipped P and T waves and long S waves in a V R, S flipped P waves, absence of Q and R waves, and long S waves in V 1, and long R waves, small S waves, and wide T waves in V 4. The second rhythm consists of R waves and elevated S T segments in lead 2, long and narrow R waves and wide S waves in a V L, small R waves and long and narrow S waves in V 2, and narrow R waves, small S waves, and elevated S T segments in V 5. The third rhythm consists of narrow Q waves, elevated R and S waves that continue up as a curved peak and then form a small dip in lead 3, narrow peak, followed by a small dip that continues up as a curved wide peak and then comes down in a V F, small R waves and long and narrow S waves in V 3, and long R waves with absence of Q and S waves in V 6. The fourth rhythm consists of long R waves with absence of Q and S waves and elevated S T segments in lead 2.

Back to Figure

The heart is surrounded by a V R on the upper left side, a V L and lead 1 on the upper right side, shaded in yellow, and lead 2, a V F, and lead 3 on the lower side, shaded in blue. The top view of the heart reveals an infarction in the anterior, lateral, and inferolateral walls. The heart is marked from V 1 to V 6. V 2 is shaded in green, V 3 and V 4 in red, and V 5 and V 6 are shaded in yellow.

Back to Figure

There are four columns and three rows. Row 1, column 1 reads, lead 1, lateral, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 1, column 2 reads, a V R. Row 1, column 3 reads, V 1 and septal. Row 1, column 4 reads, V 4 and anterior, and has a rhythm with Q wave, elevated S T segment, and flipped T wave. Row 2, column 1 reads, lead 2 and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 2, column 2 reads, a V L and high lateral, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 2, column 3 reads, V 2 and septal, and has a rhythm with small R wave, long S wave, curved S T segment, and flipped T wave. Row 2, column 4 reads, V 5 and lateral, and has a rhythm with Q wave, elevated S T segment, and flipped T wave. Row 3, column 1 reads, lead 3 and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 3, column 2 reads, a V F and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 3, column 3 reads, V 3 and anterior, and has a rhythm with Q wave, R wave, S wave, curved S T segment, and flipped T wave. Row 3, column 4 reads, V 6 and lateral, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave.

Back to Figure

The first rhythm consists of small Q waves, elevated R and S waves, and elevated S T segments in lead 1, small depressed Q R S complexes and wide T waves in a V R, small R waves, long S waves, and wide and long T waves in V 1, and long and narrow Q R S complexes and elevated and curved S T segments in V 4. The second rhythm consists of small and narrow Q R S complexes, elevated S T segments, and flipped T waves in lead 2, small and narrow Q R S complexes and waves in a V L, small R waves, long and narrow S wave, and wide T waves in V 2, and narrow and elevated Q R S complexes that continue as a curved peak in V 5. The third rhythm consists of narrow Q R S complexes and flipped T waves in lead 3, narrow Q R S complexes, elevated S T segments, and flipped T waves in a V F, long and narrow Q R S complexes, elevated S T segments and flipped T waves in V 3, and small, narrow, and elevated Q R S complexes, elevated S T segments, and flipped T waves in V 6. The fourth rhythm consists of small and narrow Q R S complexes, elevated S T segments, and flipped T waves in lead 2.

Back to Figure

The heart with infarction in the right ventricular wall, is surrounded by a V R on the upper left side, a V L and lead 1 on the upper right side, labeled as reciprocal changes, and lead 2, a V F, and lead 3 on the lower side, shaded in blue. Text reads, usually associated with I W M I and note that the vector is pointing toward lead 3 which should be taller than lead 2. The top view of the heart reveals an infarction in the right ventricular wall through which a microscope is inserted. The heart is marked from V 1 to V 6. V 1 is shaded in red, V 2 and V 3 in orange, V 4 in yellow, and V 5 and V 6 in pink.

Back to Figure

There are four columns and three rows. Row 1, column 1 reads, lead 1, lateral, and reciprocal S T depression. Row 1, column 2 reads, a V R. Row 1, column 3 reads, V 1, septal, and S T elevation, and has a rhythm with small R wave, long S wave, curved S T segment, and flipped T wave. Row 1, column 4 reads, V 4 R and right side, and has a rhythm with small R wave, long S wave, elevated S T segment, and flipped T wave. Row 2, column 1 reads, lead 2 and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 2, column 2 reads, a V L, high lateral, and reciprocal S T depression. Row 2, column 3 reads, V 2, septal, and S T depression, and has a rhythm with small R wave, long S wave, depressed S T segment, and flipped T wave. Row 2, column 4 reads, V 5 R and right side, and has a rhythm with small R wave, long S wave, elevated S T segment, and flipped T wave. Row 3, column 1 reads, lead 3, inferior, and lead 3 more than lead 2, has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 3, column 2 reads, a V F and inferior, and has a rhythm with Q wave, elevated and curved S T segment, and flipped T wave. Row 3, column 3 reads, V 3 and anterior. Row 3, column 4 reads, V 6 R and right side, and has a rhythm with small R wave, long S wave, elevated S T segment, and flipped T wave.

Back to Figure

The first rhythm consists of long and narrow R waves and depressed S T segments in lead 1, long and narrow S waves and flipped P and T waves in a V R, small R waves, long and narrow S waves, elevated S T segments, and flipped T waves in V 1, and R waves, small S waves, and curved S T segments in V 4. The second rhythm consists of Q waves, long R waves with absence of S waves in lead 2, narrow R waves and depressed S T segments in a V L, small R waves, long and narrow S waves, and curved S T segments in V 2, and long and narrow R waves and small P, S, and T waves in V 5. The third rhythm consists of Q waves, small R waves, and elevated S T segments in lead 3, Q waves, small R waves, and elevated S T segments in a V F, small R waves, long S waves, and curved S T segments in V 3, and long and narrow R waves with absence of Q and S waves in V 6. The fourth rhythm consists of Q waves, narrow R waves, elevated S T segments, and sudden dips of T waves in lead 2. V 4 R has narrow dips and curved and elevated S T segments.

Back to Figure

The heart, with an infarct in its posterior wall, is marked anteriorly with V 1 and V 2, posteriorly with V 7 and V 8, and V 9 at the site of the infarct. The first E C G has a Q wave, R wave, S T elevation, and a flipped T. The second E C G has a big R wave, S T depression, and an upright T.

Back to Figure

The posterior wall is marked as V 7, V 8, V 9, and V 10. V 7 and V 8 are shaded in one color and V 9 and V 10 in another color. The anterior wall is marked as V 1 and V 2, labeled as reciprocal changes. Text below reads, P W M I is equal to V 7, V 8, V9. Reciprocal changed in V 1 and V 2.

Back to Figure

There are four columns and three rows. Row 1, column 1 reads, lead 1 and lateral. Row 1, column 2 reads, a V R. Row 1, column 3 reads, V 1 and septal, and has a rhythm with R wave, long S wave, and depressed S T segment. Row 1, column 4 reads, V 7 and posterior, and has a rhythm with Q wave, R wave, elevated S T segment, and flipped T wave. Row 2, column 1 reads, lead 2 and inferior. Row 2, column 2 reads, a V L and high lateral. Row 2, column 3 reads, V 2 and septal, and has a rhythm with long R wave, small S wave, and depressed S T segment. Row 2, column 4 reads, V 8 and posterior, and has a rhythm with small Q wave, R wave, and elevated S T segment. Row 3, column 1 reads, lead 3 and inferior. Row 3, column 2 reads, a V F and inferior. Row 3, column 3 reads, V 3 and anterior. Row 3, column 4 reads, V 9 and posterior, and has a rhythm with small Q wave, R wave, elevated and curved S T segment, and flipped T wave.

Back to Figure

The first rhythm consists of narrow R and S waves with absence of Q waves in lead 1, Q waves, long and narrow R waves with absence of S waves in a V R, absence of Q waves, long R waves, small S waves, and depressed S T segments in V 1, and long and narrow R and S waves and depressed S T segments in V 4. The second rhythm consists of small R waves and long S waves with absence of Q waves in lead 2, Q waves and long and narrow R and S waves in a V L, long and narrow R and S waves and depressed S T segments in V 2, and long and narrow R and S waves and curved S T segments in V 5. The third rhythm consists of small R waves, long and narrow S waves, and narrow S T segments in lead 3, narrow Q R S complexes in a V F, long and narrow R and S waves and depressed S T segments in V 3, and small R waves, long S waves, and curved S T segments in V 6.

Back to Figure

The first strip, marked as 9 hours, 6 minutes, and 47 seconds, consists of Q waves, narrow R and S waves, curved S T segments, and flipped T waves. The second strip, marked as 9 hours, 7 minutes, and 1 second, consists of narrow R and S waves, curved S T segments, and flipped T waves, with absence of P and Q waves which become linear in the second half. The third strip, marked as 9 hours, 7 minutes, and 15 seconds, consists of irregular rhythms in the first half, followed by P, Q, narrow R, narrow S waves, curved S T segments, and flipped T waves.

Back to Figure

The A V node receives slow initiating waves which become fast when leaving the A V node. The E C G rhythm consists of a narrow peak, followed by a small dip, labeled as pseudo hyphen S or buried P wave, then a small curve that continues as a flat segment and then peaks again.

Back to Figure

The rhythm consists of a small dip before the P waves, Q waves, long and narrow R and S waves, curved S T segments, and flipped T waves.

Back to Figure

The rhythm consists of consecutive curved dips and curved peaks that continue as small Q R S complexes.

Back to Figure

The rhythm consists of consecutive curved dips and curved peaks that continue as a linear segment with a small curve and narrow dips at the end.

Back to Figure

The rhythm consists of P, Q, R, and S waves, and curved S T segments with absence of T waves.

Back to Figure

The rhythm consists of consecutive curved dips, curved peaks, linear segments, narrow dips, small curves, and narrow dips.

Back to Figure

The rhythm consists of consecutive narrow dips, P waves, Q waves, narrow R and S waves, curved S T segments, and flipped T waves.

Back to Figure

The first strip consists of small narrow peaks, P waves, long and narrow R waves, small and narrow S waves, dipped S T segments, and wide T waves. The second strip consists of narrow peaks, flipped P waves, narrow and elevated Q R S complexes that continue to curve up to a peak and then dip down to wide flipped T waves.

Back to Figure

The strip consists of normal waves and complexes, labeled as normal sinus rhythm, which become wider, labeled as ventricular tachycardia, V T. The rhythm has a small curve, labeled as anti tachycardia pacing, after which the waves become wider and then narrow.

Back to Figure

The strip consists of wide Q R S complexes which then stop at a narrow dip, labeled as cardioversion shock, and continue as normal Q R S complexes, labeled as normal sinus rhythm.

Back to Figure

The strip consists of narrow peak, two consecutive narrow dips, and big curved peak. This continues later as small curved peaks with flat segments in between.

Back to Figure

The heart is a fist-shaped structure having three layers on the outside, the epicardium, myocardium, and endocardium. At the inside bottom are the right and left ventricular chambers separated by an interventricular septum. Above them are the right and left auricle chambers. The mitral and tricuspid valves lie between the atria and the ventricles and have chordae tendineae, which attach the edge of the valve to the papillary muscles. The pulmonary artery carries blood from the heart and the pulmonary veins carry blood away from the heart. In the center is the aorta controlled by the aortic valve, and it ascends via the aortic arch. The major blood vessel extending upward is the superior vena cava and the inferior vena cava goes downward. The blood vessels at the top are the left common carotid artery and left subclavian artery.

Back to Figure

The various parts of the heart and blood vessels are labeled as follows. From top to bottom on the right are, the aorta, pulmonary artery, left coronary artery, left atrium, circumflex branch of the left coronary artery, anterior descending branch of the left coronary artery, and coronary vein. The parts on the left from above downward are the superior vena cava, right atrium, right coronary artery in right coronary sulcus, and the inferior vena cava.

Back to Figure

The various parts of the heart and blood vessels are labeled as follows. From top to bottom on the right are, superior vena cava, right pulmonary artery, pulmonary veins, right atrium, inferior vena cava, right ventricle, and posterior descending coronary artery in posterior interventricular groove. The parts on the left from above downward are the aorta, left pulmonary artery, pulmonary veins, left atrium, coronary sinus, and left ventricle.

Back to Figure

The different regions and the corresponding values are as follows. The unit for the pressure values is millimeters of mercury. Inferior vena cava. Oxygen saturation: greater than 80 percent. Right ventricle. Pressure: 15 to 30 over 8 to 15. Mean: 2 to 8. Left ventricle. Pressure: 100 to 140 over 60 to 80. Mean: 70 to 105. Oxygen saturation: 95 to 99 percent. Left atrium. Mean: 4 to 12. Oxygen saturation: 95 to 99 percent. Right atrium. Mean: 2 to 6. Oxygen saturation: 70 to 90 percent. Between left and right atrium. Oxygen saturation: 60 to 80 percent. Left pulmonary arteries. Pressure: 15 to 30 over 8 to 15. Mean: 9 to 18. Ascending aorta. Oxygen saturation: 95 to 99 percent. Superior vena cave. Oxygen saturation: greater than 70 percent. Aortic arch. Pressure: 100 to 140 over 60 to 80. Mean: 70 to 105.

Back to Figure

The illustration of the heart on the left is labeled Systole, closure of mitral and tricuspid valves at the start of the systole. The middle and right illustrations of the heart are labeled Diastole, closure of aortic and pulmonary valves at the end of the systole.

Back to Figure

The horizontal axis is labeled Preload and the vertical axis is labeled Stroke volume. A curvilinear line for Increased cardiac output depicts very high increased stroke volume as preload increases. A curvilinear dashed line for normal cardiac function depicts moderately high increase in stroke volume as preload increases. A curvilinear dotted line for decreased cardiac function depicts reduced stroke volume as the preload increases.

Back to Figure

The vertical axis is labeled arterial pressure in millimeters of mercury, and ranges from 40 to 100. Delta P P equals 30 percent. The waveform repeatedly increases and decreases sharply, with different amplitudes. A small notch is in the decreasing portion. The highest amplitude and lowest amplitude are labeled P P max and P P min, respectively.

Back to Figure

The human body has the various arterial and venous arterial blood vessels superimposed on it. The preferred sites for placing arterial lines are labeled as follows. Axillary artery below the collar bone, Brachial artery on the upper arm, Radial artery on the inner wrist, Femoral artery on the thigh, and Dorsalis pedis artery on the foot.

Back to Figure

The illustration depicts the anterior view of the pelvic girdle with the central artery and vein running down the spinal cord and branching toward the femurs on both sides. A medical professional is inserting a needle and syringe into the ischial tuberosity on the left, at an angle of 45 degrees.

Back to Figure

The body of a man has a vertical plane drawn down his chest that is intersected by a horizontal plane along the center of his chest. The intersection of the line from the fourth intercostal space on the right edge of the sternum with the horizontal plane is labeled the phlebostatic axis.

Back to Figure

A photo depicts the upper arm of a patient on which a long tubular instrument is affixed with two parallel tapes at the top and bottom. Tubes are shown emerging from the top and the middle portion of the instrument. Close to the top is a valve and its plastic lid is being removed by a medical professional.

Back to Figure

The common sites for inserting a central venous line are labeled as follows. The right internal jugular vein on the right side of the neck, the subclavian near the collar bone, and the brachial vein near the armpit.

Back to Figure

The illustration depicts the anterior view of the pelvic girdle with the central artery and vein running down the spinal cord and branching toward the femurs on both sides. A medical professional is inserting a needle and syringe into the ischial tuberosity on the left, at an angle of 45 degrees.

Back to Figure

An illustration of the head and chest of a man depicts the arterial and venous blood vessels. The point of insertion is at 2 inches or 5 centimeters below the manubriosternal junction to the right atrium of the heart.

Back to Figure

The illustration of a human chest depicts the heart in the center, the right ventricle below and the right auricle above it, from which the superior vena cava rises up and branches into the right arm. In the center is the pulmonary artery into which a Pulmonary artery catheter with four ports has been placed. An enlarged illustration on the side depicts the catheter ports as follows. Proximal port, port to the thermistor, port to the balloon, and the distal port.

Back to Figure

The thin and long catheter labeled 30-centimeter V I P port has a triangular piece in the center. To its right it is connected to a 26-centimeter proximal injectate port, a thermal filament ending in a 4-centimeter thermistor and a balloon right at the tip, labeled P A distal lumen. From the central attached piece, seven lumens with connectable ends, branch to the left as follows. Balloon inflation valve, thermistor connector, thermal filament connector, optical module connector, P A distal lumen hub, V I P lumen hub, and proximal injectate lumen hub.

Back to Figure

The waveform for aortic pressure decreases slightly through atrial systole corresponding to aortic systole, continues to decrease through isovolumetric contraction, increases and then decreases to a smaller extent during ventricular ejection phase corresponding to ventricular systole, then increases slightly during isovolumetric relaxation, and then decreases gradually through ventricular filling corresponding to diastole. The waveform for ventricular pressure increases and decreases slightly through atrial systole corresponding to aortic systole, and then increases to its peak and decreases during isovolumetric contraction, ventricular ejection phase corresponding to ventricular systole, and isovolumetric relaxation, and remains constant through ventricular filling corresponding to diastole. The E C G depicts the curved peak of P wave during atrial systole corresponding to aortic systole, followed by the peak and dip of the Q R S complex at the end of atrial systole and through isovolumetric contraction, the curved peak of T wave during ventricular ejection phase corresponding to ventricular systole, followed by a decrease during isovolumetric relaxation and constant portion during diastole.

Back to Figure

The horizontal axis is labeled a short systole followed by a longer diastole. The vertical axis is labeled blood pressure in millimeters of Mercury and has a range from 0 to 120 in increments of 20. A horizontal dotted line labeled Mean pressure is drawn at 90 below which is the diastolic pulse pressure up to 80 and systolic pressure up to 110. A curvilinear blood pressure waveform is plotted through (Systole, 80), (Systole, 110), (Systole, 90), (Systole, 91) forming the Dicrotic notch, curving down to (Diastole , 80).

Back to Figure

The vertical axis is labeled millimeters of mercury, and ranges from negative 10 to 40 in increments of 10. All data are approximate. The waveform depicts a repeating pattern of an increase followed by a decrease with notches, fluctuating between negative 5 and 30.

Back to Figure

The vertical axis is labeled pressure in millimeters of Mercury and has a range from 0 to 20 in increments of 10. A pulmonary artery pressure waveform is depicted by a curvilinear graph plotted between 10 and 15 millimeters of Mercury. The continuous pattern of the waveform is as follows. Systolic rise, dicrotic notch, and diastolic dip components.

Back to Figure

The vertical axis shows pressure in millimeters of Mercury and has a range from 0 to 15 in increments of 5. The waveform with slight variations is as follows. Initially is the P C W P between 7 and 5 millimeters of Mercury, followed by expiration between 11 and 15 millimeters of Mercury, Inspiration between 10 and 5 millimeters of Mercury followed by end expiration between 10 and 15 millimeters of Mercury. P C W P equals 12 millimeters of Mercury.

Back to Figure

Decreased pumping efficiency leads to decreased stroke volume and decreased cardiac output. This causes increased heart rate with decreased time in diastole which in turn causes decreased coronary perfusion. This is followed by increased M V O 2 and worsened ischemia leading to decreased pumping efficiency.

Back to Figure

The illustration of a patient’s torso and the upper half of the legs depicts the heart and the associated arteries superimposed. The intra-aortic balloon device is inserted in the femoral artery and the tip is positioned at the beginning of the descending thoracic artery. Other parts labeled are gas lumen, central lumen, aortic valve, and origin of the left subclavian artery.

Back to Figure

The X-axis is labeled as cardiac cycle. The Y-axis ranges from 80 to 120 millimeters of mercury, in increments of 20. All values are approximate. The waveform begins as a trough at 80 millimeters of mercury corresponding to unassisted end diastole. This point marks the starting of a cardiac cycle. The wave continues as a peak at 109 millimeters of mercury, corresponding to unassisted systole. The wave troughs down and takes two paths. A dotted line with a downwards slope represents the unassisted diastole. Another path leads to a peak at 120 millimeters of mercury, corresponding to augmented diastole. The curve slopes down with a minor fluctuation below the X-axis, corresponding to assisted end diastole. A cardiac cycle completes at this point. The curve continues to peak at 100 millimeters of mercury, corresponding to assisted systole.

Back to Figure

The Y-axis ranges from 40 to 120 millimeters of mercury, in increments of 40. All values are approximate. The ratio of the I A B P frequency is 1 to 1. The curve begins at 40 millimeters of mercury, corresponding to assisted end diastolic pressure. The curves peaks at 100 millimeters of mercury, corresponding to assisted systole. The curve dips a little and peaks again at 120 millimeters of mercury, corresponding to diastolic augmentation. This constitutes one cardiac cycle. Similar waveform repeats.

Back to Figure

The waveform begins as a straight line, corresponding to the T P segment. It continues as a minor peak, corresponding to P, and then straightens out to a P R segment. The P R segment is the area between the T P and the R point. The waveform, after a minor trough, peaks high, corresponding to Q R complex. Then, it flattens out as S T segment, peaks as T, and flattens as T P segment.

Back to Figure

The Y-axis ranges from 40 to 120 millimeters of mercury, in increments of 40. All values are approximate. The ratio of the I A B P frequency is 1 to 2. The curve begins at 50 millimeters of mercury, corresponding to unassisted end diastolic pressure. The curves peaks at 100 millimeters of mercury, corresponding to unassisted systole. The curve dips a little and peaks again at 120 millimeters of mercury, corresponding to diastolic augmentation. This constitutes one cardiac cycle. The curve continues into a deep trough and peaks again at 90 millimeters of mercury, corresponding to assisted systole. Similar waveform repeats.

Back to Figure

The Y-axis is labeled timing. The waveform slopes down gradually and peaks. Later it troughs at the dicrotic notch. After a minor upward slope, it gradually slopes down and starts to peak again, corresponding to the I A B inflated region.

Back to Figure

The Y-axis ranges from 40 to 120 millimeters of mercury, in increments of 40. All values are approximate. The curve begins at 80 millimeters of mercury. The curves peaks at 110 millimeters of mercury, troughs at 95 millimeters of mercury, and peaks again at 120 millimeters of mercury. Then the curve slopes down with a minor fluctuation below the X-axis. This constitutes one cardiac cycle. Similar waveform repeats. Also from the dicrotic notch, a dotted line slopes downward.

Back to Figure

The Y-axis ranges from 40 to 120 millimeters of mercury, in increments of 40. All values are approximate. The curve begins at 80 millimeters of mercury, and peaks at 110 millimeters of mercury corresponding to assisted systole. Then the curve troughs at 95 millimeters of mercury and peaks again at 120 millimeters of mercury, corresponding to diastolic augmentation. The curve slopes down with a minor fluctuation below the X-axis. This constitutes one cardiac cycle. Similar waveform repeats.

Back to Figure

The Y-axis ranges from 40 to 120 millimeters of mercury, in increments of 40. All values are approximate. The ratio of the I A B P frequency is 1 to 1. The curve begins at 40 millimeters of mercury, corresponding to assisted end diastolic pressure. It then peaks at 100 millimeters of mercury, corresponding to assisted systole. The curve dips a little and peaks again at 120 millimeters of mercury, corresponding to diastolic augmentation. This constitutes one cardiac cycle. Similar waveform repeats.

Back to Figure

The vertical axis is labeled millimeters of mercury, and ranges from 30 to 130 in increments of 50. All data are approximate. The waveform fluctuates between 45 and 125. The waveform increases to a peak value, then decreases with a notch labeled dicrotic notch. The waveform then increases sharply to a peak value, labeled unassisted systole, then slightly decreases. This is followed by a sharp increase to another peak labeled diastolic augmentation, followed by a decrease. The waveform then increases to another peak value labeled assisted systole and then decreases with a notch. The amplitude of this peak is lesser than the previous one.

Back to Figure

The vertical axis is labeled millimeters of mercury, and ranges from 40 to 120 in increments of 40. All data are approximate. The waveform fluctuates between 45 and 100. The waveform increases to a peak value, then decreases with a notch that corresponds to the aortic valve closure. The waveform then increases sharply to a peak value, labeled unassisted systole, then decreases with a notch labeled dicrotic notch. This is followed by an increase to another peak labeled diastolic augmentation, followed by a decrease. The depth of this dip is greater than the previous dip. The waveform then increases to another peak value labeled assisted systole and then decreases with a notch.

Back to Figure

The vertical axis is labeled millimeters of mercury, and ranges from 60 to 140 in increments of 20. All data are approximate. The waveform fluctuates between 65 and 135. The waveform increases gradually to a peak value, then decreases slightly. This is followed by an increase to a peak value corresponding to diastolic augmentation. This is followed by a sharp decrease to the dip with the greatest depth corresponding to assisted aortic end-diastolic pressure. The waveform then increases with fluctuations to a peak labeled assisted systole. This is followed by a decrease corresponding to unassisted aortic end-diastolic pressure, with a notch.

Back to Figure

The vertical axis is labeled millimeters of mercury, and ranges from 50 to 150 in increments of 50. All data are approximate. The waveform fluctuates between 52 and 120. The waveform increases to a peak value, then decreases gradually to a curved dip corresponding to unassisted end-diastolic pressure. This is followed by a repeating pattern of increase followed by a decrease with peaks and dips of varying amplitude. The third peak has the highest amplitude and corresponds to diastolic augmentation. The third dip corresponds to assisted end-diastolic pressure. The third and fourth dips are spaced apart, giving that portion of the waveform a widened appearance. The first, third, and fourth decreasing portions have notches.

Back to Figure

The magnified view depicts the rotor, motor, motor housing, stators, and other components. The external battery packs are strapped to the person’s shoulders. A system controller is connected to the percutaneous lead and battery packs.

Back to Figure

The magnified view depicts the motor, impeller, drive line, pump housing, cannula, and other components. The external battery packs are strapped to the person’s shoulders. A system controller is connected to the percutaneous lead and battery packs.

Back to Figure

The timeline lists years from 1990 to 2018 in increments of 4. The events in the L V A D development with their corresponding years in the timeline are as follows. 1994: first-generation L V A D approved for B T T. 2003: first-generation L V A D approved for D T. 2008: second-generation L V A D approved for B T T. 2010: second-generation L V A D approved for D T. 2012: third-generation L V A D approved for B T T. 2017: third-generation L V A D approved for D T.

Back to Figure

Blood flows to the aorta through the outflow graft, which is connected to the axial-flow pump designed for intra-abdominal placement. The pump is connected to the percutaneous drive line, which connects to the external battery pack and controller. Blood flows from the left ventricle into the inflow cannula and then through the pump. Magnified view: The blood flows around the inlet stator and blood-flow straightener, rotor bearing, rotor in the motor, outlet stator and diffuser, rotor bearing on the other side, and then exits the pump. The pump housing encompasses all these components.

Back to Figure

Blood flows to the aorta through the outflow graft, which is connected to the centrifugal-flow pump designed for intrapericardial placement. The pump is connected to the percutaneous drive line, which connects to the external battery pack and controller. Blood flows from the left ventricle into the pump. Magnified view: Blood flows into the short inflow cannula. Blood flows around the magnetic hydrodynamically levitated impeller, exits through a passage in the pump housing, and flows to the aorta. The motor is situated above the impeller.

Back to Figure

Second-generation L V A D: The external battery packs and percutaneous lead are connected to HeartMate 2 system controller. The possible causes of malfunction are as follows: malfunction during backup system controller exchange, percutaneous lead malfunction, and outflow graft cannula malfunction. Third-generation L V A D: The external battery packs and percutaneous lead are connected to HeartMate 3 system controller. The possible cause of malfunction is as follows: outflow graft cannula obstruction. L V A D system: The system controller is connected to a plug through an A C adapter. The plug connects to a socket. The system controller is also connected to a system monitor and a power base unit, P B U. P B U contains batteries in multiple slots. The possible cause of malfunction is as follows: intermittent electrical disconnection between P B U and system controller.

Back to Figure

Hypotension is defined as M A P less than 60 millimeters of mercury for continuous flow device. There are two possible categories: low L V A D flows and high L V A D flows. If high L V A D flows, consider vasodilation as cause. If no fever, consider vasodilating medications, hold vasodilators and initiate pressors. If fever; leukocytosis, consider sepsis; look for source, start broad spectrum antibiotics, initiate pressors. If low L V A D flows, consider hypovolemia, cardiac, and obstructive. There are two possibilities: low J V P and high J V P. If low J V P, there is decreased pulsatility or suction events. This can occur with low hematocrit or adequate hematocrit. Low hematocrit could be due to bleeding. Consider bolus fluids, transfuse, hold or reverse anticoagulation, and identify and treat bleeding source. If adequate hematocrit, consider hypovolemia and treatment with bolus fluids. If high J V P, perform echocardiogram and consider P A catheter placement. This could be due to tamponade, pulmonary embolus, and pneumothorax. If R V dysfunction on echo with high C V P and low P C W P, consider R V dysfunction. If no R V dysfunction on echo with high P C W P, there is inadequate unloading by L V A D. Adjust pump speed and then assess cannula position.

Back to Figure

The alarms correspond to issues in the following characteristics: flow, power, and pulsatility index. Flow, estimated, not measured: It is preload or afterload dependent. High flow corresponds to vasodilation and sepsis. Power: It is dependent on pump seed. High power corresponds to pump thrombosis. Low power corresponds to low battery. Pulsatility index: It measures pressure differential during cardiac cycle. High pulsatility index corresponds to hypervolemia, native L V recovery, and external lead damage. Low pulsatility index corresponds to hypovolemia, poor L V function, and increased pump speed.

Back to Figure

On the left is an illustration of the gastrointestinal tract depicted within the human body, starting from the mouth, esophagus, stomach, and intestines. In the middle is an enlarged illustration of the stomach, and the layers of the intestinal tissues are labeled from the outside to inside, as follows. Serosa, longitudinal muscle, circular muscle, mucosa, submucosa, and the lumen which is the interior of the gut through which food travels. On the right is a cross section of the intestinal layers arranged from inside to outside vertically as follows. They are Lumen, epithelium, lamina propina or mucosa, submucosa, circular muscle, longitudinal muscle, and Serosa.

Back to Figure

The illustration of the human body has the diagram of the gastrointestinal system superimposed on it. The various parts depicted are as follows. The esophagus going down from the throat to the diaphragm and just below it, the rounded stomach on the right, and to its left is the liver with the bile duct and gall bladder just below. The spleen is on the bottom right of the stomach. The square, tubular, scallop-edged large intestine is made up of the cecum and appendix on the bottom left, and duodenum on the top, ending in the rectum and anus. It contains the jejunum and ileum within it. An inset on the right depicts the cecum, appendix, and ascending portion of the large intestine.

Back to Figure

The scalloped tube of the large intestine is arranged in a square pattern, with the Cecum at the extreme left, and the end of the small intestine and the appendix in the corner. The ascending colon forms the left side of the square, turning right as the transverse colon and once again descending on the right as the descending colon. It bulges at the base of the sigmoid colon before ending at the rectum. Below the rectum and on either side of the anal canal are the internal anal sphincter made of smooth muscle and the external anal sphincter made of skeletal muscle.

Back to Figure

A horizontal line is drawn below the umbilicus and two parallel vertical lines are drawn on either side of it. On the bottom left is the Anterior superior iliac spine, from which a line is drawn to the umbilicus. At its intersection with the left vertical line is the McBurney point.

Back to Figure

The illustration depicts the cross section of the salivary glands. Below the tongue is the sublingual gland and below the lower jaw is the submandibular gland connected to the submandibular duct. At the end of the upper jaw is the masseter muscle and next to the ear is the parotid gland and parotid duct leading to the mouth.

Back to Figure

On top is the horizontal bell-shaped liver, below which is the rounded stomach to the right. The gall bladder is a small, rounded organ on the bottom left of the liver, and below the liver is the oval-shaped pancreas that tapers to the right. The common bile duct connects the liver to the pancreas and the pancreatic duct connects to the duodenum below the pancreas.

Back to Figure

Around the waist on either side of the spine are a pair of bean-shaped kidneys, from which tubes labeled ureters descend into a round sac labeled urinary bladder that narrows at its base to the urethra. An artery and vein are connected to the kidneys and run parallel to the ureters, branching downward on either side of the urinary bladder. On the right is a cross section of the bean-shaped kidney depicting the outer renal cortex layer and spaces within labeled renal medulla. The center of the kidney is the renal pelvis and a triangular area above it is labeled major and minor calyx.

Back to Figure

The nephron lies across the border between the cortex and the medulla. The glomerular capsule surrounds the glomerulus, which is an interconnected network of blood vessels. The afferent arteriole from systemic circulation is connected to the glomerulus. The efferent arteriole connects the glomerulus to the systemic circulation. The output from the glomerular capsule travels through the proximal convoluted tubule, descending limb, Loop of Henle, ascending limb, and distal convoluted tubule to reach the collecting duct. It exits the collecting duct as urine. A vein branches multiple times and surrounds the tubule in the ascending limb. An artery branches multiple times and surrounds the tubule in the descending limb. The multiple branches of the vein and artery are connected by vessels, forming the capillary network. A close-up view of the glomerulus depicts a network of interconnected blood vessels.

Back to Figure

The afferent arteriole carries blood into the glomerulus. The efferent arteriole carries the blood out from the glomerulus. The bowman capsule, connected to the renal tubule, surrounds the glomerulus. The glomerulus consists of a network of glomerular capillaries. The efferent arteriole is connected to the peritubular capillary. The output of glomerular filtration reaches the renal tubule and bowman capsule from the glomerular capillaries. This reaches the peritubular capillary from the renal tubule through tubular reabsorption. The tubular secretion from the peritubular capillary reaches the renal tubule. The output of renal tubule and peritubular capillary are urine and filtered blood, respectively.

Back to Figure

The structures labeled are as follows. A ureter is attached to the urinary bladder on each side. Smooth muscle surrounds the urinary bladder. There are two ureteral openings in the bladder. The internal sphincter is located at the bladder’s inferior end. The external urethral orifice is at the distal end of the urethra, which is a tube. The pelvic diaphragm connected to the external sphincter is inferior to the internal sphincter. A. Urethra is longer in men. The prostate gland is located just below the bladder and surrounds the tube attached to the distal end of the bladder. Bulbourethral, Cowper’s, glands are inferior to the prostate glands. B. Urethra is shorter in women.

Back to Figure

The parts labeled are depicted as follows. Both views: The ductus deferens is a tube connected to the testis. Seminal vesicles are a pair of glands connected to the ductus deferens. Bulbourethral glands are small glands located near the base of the penis. The epididymis is located near the testis. Testis are ovoid structures. The penis contains the urethra, a long tube, and corpus cavernosum. Front view: The ureter is a tube connected to the urinary bladder. The prostate gland is located just below the bladder and surrounds the tube attached to the distal end of the bladder. The urethra is a tube connected to the bladder. Glans penis is the rounded tip of the penis. Side view: The pubic bone is located superior to the penis and is positioned obliquely. The prostate gland is anterior to the pubic bone. The scrotum is a sac in which the testis is situated.

Back to Figure

The parts labeled are depicted as follows. Both views: The uterine, fallopian, tube connects the ovaries to the uterus. The uterus is situated closer to the bladder, overlying it. The endometrium is the lining of the uterus. Cervix is at the end of the uterus. The passage of the cervix is the cervical canal. The vagina is a tube inferior to and connected to the cervix. Front view: Ovaries are oval-shaped structures located on either side of the uterus. Side view: The urinary bladder is inferior to the uterus. The urethra is a tube connected to the urinary bladder. The pubic bone is positioned obliquely and is anterior and inferior to the urinary bladder. The clitoris is inferior to the pubic bone and is situated anteriorly. The labia is situated anteriorly, inferior to the vagina and urethra.

Back to Figure

The illustration depicts a thin, long, Minnesota tube introduced through the patient's mouth into his stomach. The small gastric balloon is within his stomach, and the longer esophageal balloon is along the length of his esophagus down his chest. The end of the tube outside his mouth has four lumens as follows. Gastric aspirate, esophageal aspirate, gastric balloon, and esophageal balloon.

Back to Figure

A. The illustration depicts the serpentine-shaped sigmoid colon, tapering to the rectum and anus. A counter-clockwise arrow around one of the curves of the colon is labeled Rotary twist. B. The illustration depicts the center portion of the serpentine-shaped sigmoid colon twisted around the top portion to form a knot or volvulus. The colon tapers to the rectum and anus.

Back to Figure

A. The diagram depicts a C-shaped normal intestine that has the appendix at its left corner and curves to the right. B. The diagram depicts the left curve of the distal ileum telescoped upward internally into the ascending cecum. A layer of mucosa surrounds the telescoped intestine.

Back to Figure

A. The diagram depicts a normal oval testicle within the scrotal sac with blood vessels running down to the testicle from behind. B. The diagram depicts testicular torsion wherein the testicle has turned and rotated on its own axis. The blood vessels running down behind it are twisted.

Back to Figure

A patient is in a supine position. A percutaneous endoscopic gastrostomy or P E G tube has been passed into the patient's stomach, through the abdominal wall. It is secured by tapes on the abdomen. The other end has two ports with lids.

Back to Figure

A patient is in a supine position. A jejunostomy tube has been passed into the patient's jejunum through the abdominal wall. It is secured by tapes on the abdomen. The other end has two ports with lids.

Back to Figure

The Jackson-Pratt drain and Hemovac drain are placed on a surface next to an array of tubes. The Jackson-Pratt drain is a squeezable, grenade-shaped bottle that has a plastic tubing inside and an outlet with a lid. In front of it is the Hemovac drain which is slightly raised and circular in shape. On the top surface are two ports with lids, labeled connectors.

Back to Figure

In the center is a triangular fulcrum with an arrow from its tip, pointing vertically to a p H value of 7.4. The p H scale has 7.4 at the top, 7.0 on the right, and 7.8 on the left. On the right side of the balance is Carbonic acid or H 2 C O 3 with a p H vale of 7.0. This has respiratory control. The balance on the left is Bicarbonate or H C O 3 minus, with a p H value of 7.8. This has renal control. The balance is horizontal.

Back to Figure

In the center is a triangular fulcrum with an arrow drawn from its tip. The p H scale has 7.4 at the top, 7.0 on the right, and 7.8 on the left. The right side of the balance is labeled Carbonic acid or H 2 C O 3 and has tilted totally to the right. The balance on the left is Bicarbonate or H C O 3 minus, and has tilted upward completely. There is a dotted rectangle above the Bicarbonate labeled Amount of Sodium lost in buffering excess acid. The arrow at the center of the fulcrum points to 7.1 on the p H scale.

Back to Figure

In the center is a triangular fulcrum with an arrow drawn from its tip. The p H scale has 7.4 at the top, 7.0 on the right, and 7.8 on the left. The right side of the balance is labeled Carbonic acid or H 2 C O 3, and an outward arrow is labeled C O 2. The balance on the left is Bicarbonate or H C O 3 minus and a rectangle above it is labeled Formation of additional bicarbonate. The balance has tilted very minimally to the right and the arrow from the fulcrum points to a little right of 7.4 on the p H scale.

Back to Figure

In the center is a triangular fulcrum with an arrow drawn from its tip. The p H scale has 7.4 at the top, 7.0 on the right, and 7.8 on the left. The right side of the balance is labeled Carbonic acid or H 2 C O 3, and has tilted totally to the right. A rectangle above it is labeled Additional carbonic acid retained owing to impaired pulmonary function. The balance on the left is Bicarbonate or H C O 3 minus indicated by a very large rectangle. The arrow at the center of the fulcrum points to 7.1 on the p H scale.

Back to Figure

In the center is a triangular fulcrum with an arrow drawn from its tip. The p H scale has 7.4 at the top, 7.0 on the right, and 7.8 on the left. The right side of the balance is labeled Carbonic acid or H 2 C O 3, and a smaller shaded rectangle is drawn above it. The balance on the left is Bicarbonate or H C O 3 minus indicated by a large rectangle with a smaller rectangle above it, labeled Formation of additional bicarbonate. The balance has tilted very minimally to the right and the arrow from the fulcrum points to a little right of 7.4 on the p H scale.

Back to Figure

In the center is a triangular fulcrum with an arrow drawn from its tip. The p H scale has 7.4 at the top, 7.0 on the right, and 7.8 on the left. The right side of the balance is labeled Carbonic acid or H 2 C O 3. The balance on the left is Bicarbonate or H C O 3 minus indicated by a large rectangle with a smaller blank, dotted rectangle labeled Additional bicarbonate. The balance has tilted completely to the left and the arrow from the fulcrum points to 7.6 on the p H scale.

Back to Figure

In the center is a triangular fulcrum with an arrow drawn from its tip. The p H scale has 7.4 at the top, 7.0 on the right, and 7.8 on the left. The right side of the balance is labeled Carbonic acid or H 2 C O 3 indicated by a small rectangle and a smaller blank, dotted rectangle labeled carbonic acid lost by hyperventilation. The balance on the left is Bicarbonate or H C O 3 minus indicated by a large rectangle. The balance has tilted completely to the left and the arrow from the fulcrum points to 7.6 on the p H scale.

Back to Figure

In the center is a triangular fulcrum with an arrow drawn from its tip. The p H scale has 7.4 at the top, 7.0 on the right, and 7.8 on the left. The right side of the balance is labeled Carbonic acid or H 2 C O 3 indicated by a small rectangle. The balance on the left is Bicarbonate or H C O 3 minus indicated by a large rectangle with a smaller blank, dotted rectangle labeled bicarbonate lost by renal excretion. The balance has tilted slightly to the left and the arrow from the fulcrum points to 7.5 on the p H scale.

Back to Figure

The components are as follows: The pineal gland is a tissue behind the third ventricle of the brain. The pituitary gland is a protrusion off the bottom of the hypothalamus at the base of the brain. Parathyroid glands are located at the neck of humans. The thyroid is situated anteriorly below the skin and muscle layers. Adrenal glands are located at the superior portion of each kidney. It has an outer portion called the adrenal cortex and an inner portion called the adrenal medulla. The pancreas is located in the abdomen behind the stomach. Ovaries are an organ found in the female reproductive system on each side of the body. Testes are two oval organs, and a part of the male reproductive system.

Back to Figure

The various hormones are as follows: Gonadotropic hormones such as Follicle-stimulating hormone, F S H, and luteinizing hormone, L H, both act on testes and ovaries. Hypothalamus is present at the center of the brain, near the pituitary gland. It has small neuron-like structures called neurosecretory cells. A protrusion off the bottom of the hypothalamus is called the pituitary gland. It has two lobes, the anterior pituitary lobe and the posterior pituitary lobe.

Blood inflows and outflows from these lobes to the hormones. The anterior pituitary lobe secretes hormones such as gonadotropic hormones present in ovaries and testes, adrenocorticotropic hormone, A C T H, present in the adrenal cortex, thyroid-stimulating hormone, T S H, present in thyroid, growth hormone, G H, present in bone and most soft tissues, melanocyte-stimulating hormone, M S H, present in melanocytes in skin, and prolactin present in mammary glands. The posterior pituitary lobe secretes hormones such as oxytocin present in muscles of the uterus and mammary glands, and antidiuretic hormone, A D H, present in kidney tubules.

Back to Figure

Adrenal glands are found above the kidney. Each gland has an outer adrenal cortex and an inner adrenal medulla.

Back to Figure

The pancreas comprises the pancreatic duct and the islets of Langerhans which are cell groups within the pancreas that act as an organ within an organ. There is a magnified image of islets of Langerhans cells which secretes hormones into blood vessels.

Back to Figure

The images represent two people in different conditions and the responses caused by the hypothalamus. The two conditions and the responses are as follows. Hot environment; body temperature decreases leading to stimulated hypothalamus, blood vessels dilate, thereby maximizing heat loss from the skin, and the body sweats causing evaporation and cooling. Cold environment; body temperature increases leading to stimulated hypothalamus, blood vessels constrict, thereby minimizing heat loss from the skin, and muscles shiver, generating heat.

Back to Figure

The first illustration depicts various capillaries, vessels, ducts, nodes, and organs in the body as follows: Tonsil, Lymph node, Thymus, Spleen, Peyer’s patch (small intestine), Lymph node, Bone marrow, Lymphatic vessels, Right lymphatic duct, Subclavian vein, Superior vena cava, Thoracic duct, and Appendix. The second illustration depicts the passage of lymph through vein and artery connected by venules and capillaries and the flow of lymph into the tissues through a valve connected to the lymph node. There is an arteriole and venule connected to capillaries. The arteriole is an extension of the artery and the venule is an extension of the vein.

Back to Figure

The outline includes the eye, the skin, the mucus membranes of the respiratory tract, and the digestive system.

Back to Figure

The virus has a three-layered structure. The R N A genome, plus strand, is enclosed within a multi-layered protein capsid which is also guarded by a multi-layered matrix. The R N A genome has a reverse transcriptase molecule attached to it. There are stalk-like structures protruding from the matrix till outside the virus wall called envelope spikes. A two-layered outer membrane called viral envelope is guarding all the other structures.

Back to Figure

In the transmission cycle, the mosquito is the bridge vector transmitting the infection to birds, humans, and horses.

Back to Figure

Three people are fully covered with personal protective equipment, P P E. One person is in yellow P P E and the other two are in white P P E with yellow border lines. One is holding an oxygen P P E mask and the other person is holding a gun-like medical equipment, trying to place it on the injured person’s knee.

Back to Figure

The sequence for donning P P E is as follows: Fully cover the gown from neck to knees, arms to end of wrists, and wrap around the back. Fasten the gown in the back of the neck and waist. Cover the face and below the chin with mask or respirator, tying it to the middle of head and neck. Fit flexible band to nose bridge. Fit-check respirator. Goggles or face shields should be placed over the face and eyes and adjusted to fit. Gloves should cover the wrist. The sequence for removing the P P E is as follows: Outside of gloves are contaminated, so hold outside of glove with the opposite gloved hand and peel off. Hold the removed glove in the gloved hand. Slide fingers of ungloved hand under remaining glove at the wrist. Peel gloves off and discard. Remove the goggles or face shield by headband or earpieces. Unfasten gown ties and pull away from neck and shoulders, fold it, and discard. Grasp the bottom of the mask and remove it. Discard in a waste container.

Back to Figure

The horizontal axis is labeled hours after ingestion, ranging from 0 to 24 with increments of 4. The vertical axis is labeled as micrograms per milliliter, ranging from 5 to 1000. There is also a vertical scale labeled as acetaminophen plasma concentration, S I units, in micromolar per liter, ranging from 10 to 6000. The nomogram has two sloping lines parallel to each other. The upper position of the lines indicates probable hepatic toxicity, the middle position indicates possible hepatic toxicity, and the lower position indicates no hepatic toxicity.

Back to Figure

The anatomical structure is labeled with the following parts from left to right: Ovary, Egg, Fallopian Tube, and Uterus. The cycle comprises four phases. Phase 1. Day 1 through 6, Menstrual Phase, discharge. Phase 2. Day 6 through 13, Preovulatory Phase. Phase 3. Day 14. Ovulation. Day 16 through 28. Postovulatory Phase.

Back to Figure

The anatomical structure is labeled with the following parts, from top to bottom: Placenta, Umbilical Cord, Amniotic Cavity, Uterus, and Lumen of Uterus. The full-grown fetus' head is cradled against the Lumen of the Uterus.

Back to Figure

The structures labeled from top to bottom are as follows: Arterial Duct, Dudus Arteriosus, low oxygen concentration. Pulmonary Artery. Superior Vena Cava, very low oxygen concentration. Pulmonary Veins, very low oxygen concentration. Foramen Ovale. Lungs. Heart. Dorsal Aorta, low oxygen concentration. Liver. Venous Duct, Ductus Venosus, very high oxygen concentration. Inferior Vena Cava, very low oxygen concentration. Umbilicus, Navel. Umbilical Cord, low oxygen concentration. Umbilical Vein, very high oxygen concentration. Umbilical Arteries. Placenta.

Back to Figure

The structures labeled from top to bottom are as follows: Ligamentum Arteriosum, very low oxygen concentration. Fossa Ovalis, Closed Foramen Ovale. Ligamentum Tetes, very low oxygen concentration. Umbilical Ligaments, very low oxygen concentration.

Back to Figure

The reading on the detail heart rate strip is stable at around 150 units. The reading on the contraction strip peaks to 35 units at roughly uniform intervals.

Back to Figure

The structures labeled from top to bottom are as follows: Arterial Duct, Dudus Arteriosus, low oxygen concentration. Pulmonary Artery. Superior Vena Cava, very low oxygen concentration. Pulmonary Veins, very low oxygen concentration. Foramen Ovale. Lungs. Heart. Dorsal Aorta, low oxygen concentration. Liver. Venous Duct, Ductus Venosus, very high oxygen concentration. Inferior Vena Cava, very low oxygen concentration. Umbilicus, Navel. Umbilical Cord, low oxygen concentration. Umbilical Vein, very high oxygen concentration. Umbilical Arteries. Placenta. The structures labeled from top to bottom are as follows: Ligamentum Arteriosum, very low oxygen concentration. Fossa Ovalis, Closed Foramen Ovale. Ligamentum Tetes, very low oxygen concentration. Umbilical Ligaments, very low oxygen concentration. The structures labeled from top to bottom are as follows: Ligamentum Arteriosum, very low oxygen concentration. Fossa Ovalis, Closed Foramen

Ovale. Ligamentum Tetes, very low oxygen concentration. Umbilical Ligaments, very low oxygen concentration.

Back to Figure

The data from the process diagram are as follows. Antenatal counseling Team briefing and equipment check. Steps 1 through 7 are to be executed in one minute. Step 1. Birth. Step 2. Term gestation, question mark. Good tone, question mark. Breathing or crying, question mark. If Yes, Step 3. Infant stays with mother for routine care, warm and maintain normal temperature, position airway, clear secretions if needed, dry. Ongoing evaluation. If No, Step 4. Warm and maintain normal temperature, position airway, clear secretions if needed, dry, stimulate. Step 5. Apnea or gasping, question mark. Heart Rate below 100 per minute, question mark. If No, Steps 6 through 8. If Yes, Steps 9 through 10. Step 6. Labored breathing or persistent cyanosis, question mark. Step 7. Position and clear airway. S p o 2 monitor. Supplementary O 2 as needed. Consider C P A P. Step 8. Postresuscitation care. Team debriefing. Step 9. P P V, S P O 2 monitor, Consider E C G monitor. Step 10. Heart Rate below 100 per minute, question mark. If No, Step 8. If Yes, Step 11. Check chest movement. Ventilation corrective steps if needed E T T or laryngeal mask if needed. Step 12. Heart Rate below 60 per minute, question mark. If Yes, Step 13. Intubate if not already done. Chest compressions. Coordinate with P P V. 100 percent O 2. E C G Monitor. Consider emergency U V C. Step 14. Heart Rate below 60 per minute, question mark. If Yes, Step 15. I V epinephrine. If Heart Rate is persistently below 60 per minute, consider hypovolemia. Consider pneumothorax.

Back to Figure

One pair of gloved hands holds a bag-mask ventilation over the infant’s nose and mouth. The other pair of gloved hands demonstrates the two-thumbs, encircling-hands technique. The thumbs are placed on the infant’s chest, and the other fingers are positioned along the sides of the infant.

Back to Figure

One gloved hand cradles the crown of the infant in supine position. The index finger and the middle finger of the other gloved hand press gently on the infant’s chest.

Back to Figure

The neonate is in supine position with the right arm raised over the head. A needle is inserted at a 60-degree angle from below the right armpit and above the nipple to the second intercostal space, midclavicular line.

Back to Figure

The following parts of the chest are labeled from outside to inside: skin, pectoralis muscle, intercostal muscle, second rib, second rib intercostal space, third rib, neurovascular bundle, parietal pleura, visceral pleura, fourth rib, and lung. The angle between the needle and the skin is 90 degrees.

Back to Figure

The first part of the diagram depicts a closeup of cord, such that the neonate’s head is on the left and feet are to the right. The umbilical vein is identified at the top of the cord, toward the head. The umbilical arteries are identified at the bottom of the cord, toward the feet. The second part of the diagram depicts a catheter being inserted through the umbilical vein and to the portal vein, toward the neonate’s head.

Back to Figure

The first part of the diagram depicts a closeup of a catheter through a neonate’s umbilical vein. The second part of the diagram depicts the correct depth of insertion of the catheter; 0.75 inches to 1.5 inches. The third part of the diagram depicts the incorrect depth of insertion of the catheter, reaching the neonate’s liver.

Back to Figure

The data from the graph for the adult are as follows. The heart rate is stable at the beginning, but increases almost steadily with increase in shock severity. The blood pressure is stable at the beginning, but higher than that of the heart rate and decreases in a concave-down manner. The data from the graph for the child are as follows. The heart rate, lower than that of the adult, is stable for a very short period, before increasing in a concave-up manner and stabilizing at a level above that of the blood pressure. The blood pressure, initially stable for a longer period than that of the heart rate, drops drastically with increase in shock severity.

Back to Figure

The following parts are labeled in the top view: anterior fontanelle, near the front of the skull, and posterior fontanelle, near the back of the skull. The following parts are labeled in the lateral view: anterior fontanelle, at the crown, sphenoidal fontanelle, behind the eye socket, and mastoid fontanelle, at the base of the skull.

Back to Figure

Scale 0. Happy face. No hurt. Scale 2. Less happy face. Hurts a little bit. Scale 4. Neutral face. Hurts little more. Scale 6. Sad face. Hurts even more. Scale 8. Sadder face. Hurts whole lot. Scale 10. Crying face. Hurts worst.

Back to Figure

Stage 1. Signs of shock. Decrease in mean arterial pressure. Early signs: Map decrease of 10 millimeters of mercury from baseline. Effective compensation. Oxygen to vital organs. Increased heart rate. Stage 2. Compensatory signs, non-progressive. Map decrease of 10 to 15 millimeters of mercury from baseline. Increased renin.

Decreased A D H. Vasoconstriction. Decreased pulse pressure. Increased heart rate. Decreased p H. Restless. Apprehensive. Stage 3. Progressive signs, intermediate. Map decrease of 20 millimeters of mercury from baseline. Tissue or organ hypoxia. Reduced urine, oliguria. Weak rapid pulse. Reduced p H. Sensory neural changes. Stage 4. Refractory signs, irreversible. Excessive pelt or organ damage. Multi-system organ failure. Decreased p H.

Back to Figure

The following sections of the spine are labeled, from the top to the bottom: occipital region, cervical, thoracic, and lumbar. The occipital region and the upper cervical section of the spine are more commonly injured in children under age 9.

Back to Figure

In the illustration, a needle is inserted from under the right arm and the above the right nipple, between the second and the third intercostal space. In the diagram, the following parts of the chest are labeled from the outside to the inside: skin, pectoralis muscle, intercostal muscle, second rib, second rib intercostal space, third rib, neurovascular bundle, parietal pleura, visceral pleura, fourth rib, and lung. The angle between the needle and the skin is 90 degrees.

Back to Figure

The following parts of the diagram are identified and labeled from the top to the bottom: diaphragm, esophagus, small gastric pouch, adjustable gastric band, along the upper abdomen, remainder of stomach, and small intestine.

Back to Figure

The following parts of the diagram are identified and labeled, from the top to the bottom: liver, common hepatic duct, common bile duct, alimentary limb, colon, common channel, and biliopancreatic limb.

Back to Figure

The following parts of the diagram are labeled, from the top to the bottom: esophagus, small gastric pouch, alimentary or Roux limb, pylorus, duodenum, and excluded portion of stomach.

Back to Figure

The diagram comprises three levels. Level 1, Top: Congenital Heart Disease. Level 2, Middle: Acyanotic Defects and Cyanotic Defects. Level 3, Bottom: Under Acyanotic Defects: Increased Pulmonary Blood Flow and Obstructive Blood Flow from Heart. Level 3, Bottom, Under Cyanotic Defects: Decreased Pulmonary Blood Flow and Mixed Blood Flow.

Back to Figure

Blood flow in the heart is traced from the left atria to the aorta. Blood also flows from the right atria to the right ventricle and to the aorta and the superior vena cava.

Back to Figure

Blood flow in the heart is traced from the left atria to the left ventricle, aorta, and the superior vena cava. Blood also flows from the right atria to the left atria.

Back to Figure

Blood flow in the heart is traced from the left ventricle to the superior vena cava and from the right ventricle to the aorta.

Back to Figure

Blood flow in the heart is traced from the right ventricle to the superior vena cava and the aorta.

Back to Figure

One gloved hand lifts the infant’s arm over the head. The index and middle fingers of the other gloved hand press gently under the upper arm of the neonate.

Back to Unnumbered Figure

The table shows four columns: Huddle, Debriefing, Interview, and R C A. Row entries are as follows. Row 1. Objective. Huddle: Determine what happened. Stabilize patient. Address staff concerns. Secure all equipment. Debriefing: Clarify timeline of event. Assess ongoing safety risks. Determine need for emotional support to staff, patient and family. Interview: Further investigation to obtain information and details not uncovered via debriefing. R C A: Determine root causes of event. Use tools to depict standard process and redesigned process. Determine system versus individual culpability. Row 2. When? Huddle: Immediately, within 24 hours. Debriefing: 24 to 72 hours after event. Interview: Post debriefing, in preparation for root cause analysis. R C A: Within 2 weeks of event. Row 3. Who participates? Huddle: Staff directly involved in event. Debriefing: Staff directly involved in event. Interview: Interviewer and staff involved in event. R C A: Frontline staff and local leadership not directly involved in event. C M O. Risk and Q M content experts. Row 4. Who leads? Huddle: Most-senior local staff members, typically R N unit managers. Debriefing: C M O. Interview: Trained interviewer, typically Q A and R M staff. R C A: C M O or vice president or director for risk management. Row 5. Training. Huddle: R N unit managers, or supervisors, night and evening administrators. Conducted internally by each facility. Debriefing: S A E workgroup to facilitate, cross-pollination, of expertise among C M Os. Interview: Q A and R M. Q I nurses. Conducted centrally by a risk management organization. R C A: S A E workgroup to facilitate, cross-pollination, of expertise among C M Os and R M. Text below the table reads, Abbreviations: C M O, chief medical officer; O R, operating room; Q A, quality assurance; Q I, quality improvement; Q M, quality management; R C A, root cause analysis; R M, risk management; R N, registered nurse; S A E, serious adverse event. Source line reads, Prepared in accordance with New York State Public Heath Law 2805 j through m; New York State Education Law 6527; and Federal Law 109-4.

Back to Table

The table shows eight columns: Processes and Subprocesses; Failure Modes, What Might Happen; Causes, Why It Happens; Effects; Severity; Probability; Hazard Score; and Actions to Reduce Failure Mode. Under Prescribing, row entries are as follows. Row 1. Processes and Subprocesses: Assess patient. Failure Modes: Inaccurate pain assessment. Causes: Cultural influences; patient unable to articulate. Effects: Poor pain control. Severity: 2. Probability: 4. Hazard Score: 8. Actions to Reduce Failure Mode: Standard scale to help assess pain; training on cultural influences. Row 2. Processes and Subprocesses: Choose analgesic or mode of delivery. Failure Modes: Wrong analgesic selected. Causes: Clinical situation not considered, age, renal function, allergies, etcetera; tolerance to opiates not considered; standard P C A protocols not followed, or not available; concomitant use of other analgesics not considered; drug storage; knowledge deficit; improper selection of patients appropriate for P C A. Effects: Improper dosing; improper drug; allergic response; improper use of substitute drug. Severity: 4. Probability: 3.

Hazard Score: 12. Actions to Reduce Failure Mode: C P O E with decision support, clinical pharmacy program; standard P C A protocol with education on use; point-of-use access to drug information; feedback mechanism on drug shortages with information on substitute drugs available; selection criteria for P C A patients. Row 3. Processes and Subprocesses: Prescribe analgesic. Failure Modes: Wrong dose, loading, P C A, constant, lock-out, route, frequency. Causes: Knowledge deficit; mental slip; wrong selection from list; information about drug not available. Effects: Overdose; underdose; A D R. Severity: 4. Probability: 3. Hazard Score: 12. Actions to Reduce Failure Mode: C P O E with decision support; clinical pharmacy program; standard P C A protocols. Row 4. Processes and Subprocesses: Prescribe analgesic. Failure Modes: Proper patient monitoring not ordered. Causes: Knowledge deficit; mental slip. Effects: Failure to detect problems early to prevent harm. Severity: 4. Probability: 3. Hazard Score: 12. Actions to Reduce Failure Mode: Standard P C A order sets with monitoring guidelines. Row 5. Processes and Subprocesses: Prescribe analgesic. Failure Modes: Prescribed to wrong patient. Causes: Similar patient names; patient identifier not clear; name does not appear on screen when ordering medications. Effects: Wrong patient receives inappropriate drug and dose; A D R; allergic response. Severity: 3. Probability: 3. Hazard Score: 9. Actions to Reduce Failure Mode: Match therapy to patient condition; alerts for look-alike patient names; visible demographic information on order form or screen. Row 6.

Processes and Subprocesses: Prescribe analgesic. Failure Modes: No order received. Causes: Unable to reach covering physician. Effects: Poor pain control. Severity: 2. Probability: 2. Hazard Score: 4. Actions to Reduce Failure Mode: Proper physician coverage and communication channels. Text below the table reads, Abbreviations: A D R, adverse drug reaction; C P O E, computerized physician order entry; I V, intravenous; P C A, patient-controlled analgesia. Source line reads, Adapted from Institute for Safe Medication Practices.

Back to Table

The table shows six columns: Altitude in feet; Atmospheric Pressure in millimeters of mercury; P a o 2 in millimeters of mercury, superscript a; P v o 2 in millimeters of mercury; Pressure Differential in millimeters of mercury; and Blood Saturation in percent, superscript a. Row entries are as follows. Row 1. Sea level; 760; 100; 40; 60; 98. Row 2. 10,000; 523; 60; 31; 29; 87. Row 3. 18,000; 380; 38; 26; 12; 72. Row 4. 22,000; 321; 30; 22; 8; 60. Row 5. 25,000; 282; 7; 4; 3; 9. Row 6. 35,000; 179; 0; 0; 0; 0. Text for superscript a reads, These are average measurements for a healthy patient. Text below the table reads, Abbreviations: P a o 2, partial pressure of oxygen, arterial; P v o 2, partial pressure of oxygen, venous.

Back to Table

The table shows four columns: Indifferent Stage, Compensatory Stage, Disturbance Stage, and Critical Stage. Row entries are as follows. Row 1. Altitude in feet: 0 to 10,000. 10,000 to 15,000. 15,000 to 20,000. 20,000 to 25,000. Row 2. Oxygen saturation in percent: 98 to 90. 89 to 80. 79 to 70. 69 to 60. Row 3. Symptoms: Decrease in night vision. Drowsiness, Poor judgment, Impaired coordination, Impaired efficiency. Impaired flight control, Impaired handwriting, Impaired speech. Circulatory failure.

Back to Table

The table shows four main columns: Location; Day; Night; and Night, with N V I S or H T A W S. Day is further divided into two: Ceiling and Visibility, superscript a. Night is further divided into two: Ceiling and Visibility. Night, with N V I S or H T A W S is further divided into two: Ceiling and Visibility. Row entries are as follows. Row 1. Nonmountainous, local. 800 feet. 2 statute miles. 1,000 feet. 3 statute miles. 800 feet. 3 statute miles. Row 2. Nonmountainous, nonlocal. 800 feet. 3 statute miles. 1,000 feet. 5 statute miles. 1,000 feet. 5 statute miles. Row 3. Mountainous, local. 800 feet. 3 statute miles. 1,500 feet. 3 statute miles. 1,000 feet. 5 statute miles. Row 4. Mountainous, nonlocal. 1,000 feet. 3 statute miles. 1,500 feet. 5 statute miles. 1,000 feet. 5 statute miles. Text for superscript a reads, A statute mile equals 5,280 feet, or 1,760 yards, 1.609 kilometers. Text below the table reads, Abbreviations: H T A W S, helicopter terrain awareness and warning system; N V I S, night vision imaging system. Source line reads, Data from Federal Aviation Administration. Helicopter air ambulance, commercial helicopter, and Part 91 helicopter operations. Back to Table

Text is listed under three heads. Under head Eye Opening, the following are listed. Spontaneous: Score 4. In response to sound: Score 3. In response to pressure: Score 2. No response: Score 1. Under head Best Verbal Response, the following are listed. Oriented conversation: Score 5. Confused conversation: Score 4. Words: Score 3. Sounds: Score 2. None: Score 1. Under head Best Motor Response, the following are listed. Obeys commands: Score 6. Localizes to pressure: Score 5. Withdraws from pressure: Score 4. Abnormal flexion: Score 3. Extension: Score 2. No response: Score 1. Text for superscript a reads, Some systems use a, Not testable, N T, score for any element that cannot be tested. Eye opening cannot be tested in a patient whose eyes are closed due to a local factor, such as swelling; verbal response cannot be tested in a patient who has a preexisting factor interfering with communication, such as mutism; and motor response cannot be tested in a patient who has preexisting paralysis or other limiting factor. Text below the table reads, Score: 13 to 15 may indicate mild dysfunction, although 15 is the score a person without neurologic impairment would receive. Score: 9 to 12 may indicate moderate dysfunction. Score: 8 or less is indicative of severe dysfunction.

Back to Table

The table shows four columns: Category, 0, 1, and 2. Row entries are as follows. Row 1. Face. Disinterested, no expression. Occasional grimace, withdrawn. Frequent frown, clenched jaw. Row 2. Legs. No position or relaxed. Uneasy, restless, tense. Kicking or legs drawn up. Row 3. Activity. Normal position, moves easily. Squirming, tense. Arched, rigid, or jerking. Row 4. Cry. No crying. Moans or whimpers. Cries steadily, screams, or sobs. Row 5. Consolability. Content, relaxed. Distractible. Inconsolable. Text below the table reads, Scores add up and range from 0 to 10.

Back to Table

The table shows four columns: Category, 0, 1, and 2. Row entries are as follows. Row 1. Crying. None. High-pitched. Inconsolable. Row 2. Requires oxygen. None. Less than 30 percent F i o 2 needed. Greater than 30 percent F i o 2 needed. Row 3. Increased vital signs. Normal H R and B P. Increased H R and B P less than 20 percent. Increased H R and B P greater than 20 percent. Row 4. Expression. Normal. Grimace. Grimace and grunt. Row 5. Sleeplessness. None. Wakes frequently. Awake constantly. Text below the table reads, Abbreviations: B P, blood pressure; F i o 2, fraction of inspired oxygen; H R, heart rate.

Back to Table

The table shows three section. The first section is titled Normal Arterial Values and lists the following entries. p H: 7.35 to 7.45. P a c o 2: 35 to 45 millimeters of mercury. H C O 3 negative: 22 to 26 milliequivalents per liter. O 2 Saturation: 96 percent to 100 percent. P a o 2: 80 to 100 millimeters of mercury. B E: negative 2 to positive 2 millimoles per liter. The second section is titled Abnormal Values and contains four columns: p H, P a c o 2, H C O 3 negative, and Acid–Base Imbalance. Row entries are as follows. Row 1. Decreases, increases, Normal, Respiratory acidosis. Row 2. Increases, decreases, Normal, Respiratory alkalosis. Row 3. Decreases, Normal, Decreases, Metabolic acidosis. Row 4. Increases, Normal, increases, Metabolic alkalosis. Row 5. Decreases, increases, increases, Respiratory acidosis with metabolic compensation. Row 6. Increases, increases, increases, Metabolic alkalosis with respiratory compensation. Row 7. Decreases, increases, decreases, Metabolic and respiratory acidosis. Row 8. Increases, decreases, increases, Metabolic and respiratory alkalosis. The third section is titled Normal Venous Values and lists the following entries. p H: 7.32 to 7.43. P a c o 2: 38

to 50 millimeters of mercury. H C O 3 negative: 22 to 29 milliequivalents per liter. O 2 Saturation: 60 percent to 85 percent. P a o 2: 40 millimeters of mercury. B E: 0 to positive 4 millimoles per liter.

Back to Table

The table shows four columns: Size, Connector Color, Height and Weight Criteria, and Cuff Volume. Row entries are as follows. Row 1. Size 2. Green. 35 to 45 inches or 12 to 25 kilograms. 25 to 35 milliliters, asterisk. Row 2. Size 2.5. Orange. 41 to 51 inches or 25 to 35 kilograms. 30 to 40 milliliters, asterisk. Row 3. Size 3. Yellow. 4 to 5 feet. L T-D, 45 to 60 milliliters; L T S-D, 40 to 55 milliliters. Row 4. Size 4. Red. 5 to 6 feet. L T-D, 60 to 80 milliliters; L T S-D, 50 to 70 milliliters. Row 5. Size 5. Purple. Greater than 6 feet. L T-D, 70 to 90 milliliters; L T S-D, 60 to 80 milliliters. Text for asterisk reads, Sizes 2 and 2.5 are available only in the King L T-D.

Back to Table

The table shows seven columns: Drug Category, Drug Name, Dose, Onset, Duration, Advantages, and Disadvantages. Row entries are as follows. Row 1. Drug Category: Benzodiazepines. Drug Name: Midazolam, Versed. Dose: 2 to 5 milligrams on induction; 5 milligrams as needed for sedation. Onset: 30 to 60 seconds. Duration: 15 to 30 minutes. Advantages: Provide amnesia, hypnosis, sedation. Anticonvulsant properties. Disadvantages: Vasodilation, hypotension, myocardial depression. Row 2. Drug Category: Benzodiazepines. Drug Name: Lorazepam, Ativan. Dose: 0.03 to 0.06 milligrams per kilogram. Onset: 1 to 2 minutes. Duration: 1 to 2 hours. Advantages: No data. Disadvantages: No data. Row 3. Drug Category: Benzodiazepines. Drug Name: Diazepam, Valium. Dose: 0.3 to 0.6 milligrams per kilogram. Onset: 45 to 60 seconds. Duration: 15 to 30 minutes. Advantages: No data. Disadvantages: No data. Row 4. Drug Category: Anesthetic agents. Drug Name: Etomidate, Amidate. Dose: 0.2 to 0.6 milligrams per kilogram. Onset: 15 to 45 seconds. Duration: 3 to 12 minutes. Advantages: Usual induction dose is 0.3 milligrams per kilogram. Preferred induction agent for R S I secondary to its rapid onset, short duration, and stable hemodynamic profile. Cerebroprotective, reducing cerebral blood flow and metabolism in the setting of elevated I C P. Disadvantages: Injection site pain secondary to the diluent, propylene glycol. Myoclonic movements that may mimic seizure activity. Not F D A approved for use in pediatric patients, although many published reports in pediatric patients report no adverse effects. Plasma cortisol suppression has also been reported with long-term etomidate use in the I C U environment. Short-term use in R S I has not shown cortisol suppression. The table shows seven columns: Drug Category, Drug Name, Dose, Onset, Duration, Advantages, and Disadvantages. Row entries are as follows. Row 5. Drug Category: Anesthetic agents. Drug Name:

Ketamine, Ketalar. Dose: 1 to 2 milligrams per kilogram. Onset: 45 to 60 seconds. Duration: 10 to 20 minutes. Advantages: Phencyclidine derivative with analgesic, anesthetic, and amnestic properties. Also has a stable hemodynamic profile secondary to catecholamine release and stimulation of the sympathetic nervous system. Also a bronchodilator, making it an ideal induction agent in the setting of bronchospasm. Disadvantages: Emergence reactions are an occasional complication of ketamine administration. Reactions are rarely an issue when ketamine is used in the setting of R S I because the benzodiazepine used for post-R S I sedation attenuates this response. Row 6. Drug Category: Anesthetic agents. Drug Name: Propofol, Diprivan. Dose: 1 to 2 milligrams per kilograms. Onset: 15 to 45 seconds. Duration: 5 to 10 minutes. Advantages: Decreases cerebral oxygen demand and I C P. Disadvantages: Vasodilation and myocardial depression, which may result in hypotension and a subsequent reduction in C P P. Pain at injection site. Row 7. Drug Category: Opiates. Drug Name: Fentanyl, Sublimaze. Dose: 2 to 3 micrograms per kilogram. Onset: 3 to 5 minutes. Duration: 30 to 60 minutes. Advantages: Attenuation of the sympathetic response to laryngoscopy. Disadvantages: Hypotension and apnea. Potential for chest wall rigidity: May administer dose in fractional amounts. If rigidity occurs and paralysis is not indicated, treat with naloxone 1 to 10 micrograms per kilogram. Text below the table reads, Abbreviations: C P P, cerebral perfusion pressure; F D A, Food and Drug

Administration; I C P, intracranial pressure; I C U, intensive care unit; R S I, rapid sequence intubation.

Back to Table

The table shows seven columns: Drug Category, Drug Name, Dose, Onset, Duration, Advantages, and Disadvantages. Row entries are as follows. Row 1. Drug Category: Depolarizing neuromuscular blocking agents. Drug Name: Succinylcholine; Anectine, Quelicin. Dose: 1 to 2 milligrams per kilogram. Onset: Less than 1 minute. Duration: 5 minutes. Advantages: Rapid onset, short duration of action. Disadvantages: Fasciculations. Hyperkalemia. Increased intracranial pressure, increased intraocular pressure, and increased intragastric pressure. May cause or worsen bradycardia, particularly in pediatric patients. Has been implicated in malignant hyperthermia and may cause prolonged neuromuscular blockade. Row 2. Drug Category: Nondepolarizing neuromuscular blocking agents. Drug Name: Vecuronium, Norcuron. Dose: For intubation: 0.15 milligrams per kilogram. Postintubation paralysis: 0.01 to 0.1 milligrams per kilogram. Onset: 90 to 120 seconds. Duration: 60 to 75 minutes. Advantages: Longer duration means that effects are less likely to wear off during transport. Disadvantages: Possible prolonged paralysis with long-term use; renal or hepatic dysfunction. Possible prolonged paralysis with concurrent use of corticosteroids. No effect on level of consciousness, so must be administered with adequate anesthesia, analgesia, or sedation. In patients with apnea, establish a patent airway prior to use. Row 3. Drug Category: Nondepolarizing neuromuscular blocking agents. Drug Name: Rocuronium, Zemuron. Dose: For intubation: 0.6 to 1.2 milligrams per kilogram. Postintubation paralysis: 0.1 to 0.2 milligrams per kilogram. Onset: Less than 2 minutes. Duration: 30 to 60 minutes. Advantages: No data. Disadvantages: No data. Row 4. Drug Category: Nondepolarizing neuromuscular blocking agents. Drug Name: Pancuronium, Pavulon. Dose: For intubation: 0.1 milligram per kilogram. Postintubation paralysis: 0.015 to 0.1 milligram per kilogram. Onset: 1 to 2 minutes. Duration: 45 to 60 minutes. Advantages: No data. Disadvantages: No data. Row 5. Drug Category: Nondepolarizing neuromuscular blocking agents. Drug Name: Cisatracurium, Nimbex. Dose: For intubation: 0.15 to 0.2 milligrams per kilograms. Postintubation paralysis: 0.03 milligrams per kilogram. Onset: 2 to 3 minutes. Duration: 30 to 40 minutes. Advantages: No data. Disadvantages: No data. Row 6. Drug Category: Nondepolarizing neuromuscular blocking agents. Drug Name: Atracurium, Tracrium. Dose: For intubation: 0.5 milligrams per kilogram. Postintubation paralysis: 0.5 milligrams per kilogram per hour. Onset: 2 to 3 minutes. Duration: 45 to 60 minutes. Advantages: No data. Disadvantages: No data.

Back to Table

The table shows seven columns: Height in inches, P B W in kilogram, 4 milliliters, 5 milliliters, 6 milliliters, 7 milliliters, and

8 milliliters. Under female, row entries are as follows. Row 1. 4 feet 0 inch, 48; 17.9; 72; 90; 107; 125; 143. Row 2. 4 feet 1 inch, 49; 20.2; 81; 101; 121; 141; 162. Row 3. 4 feet 2 inches, 50; 22.5; 90; 113; 135; 158; 180. Row 4. 4 feet 3 inches, 51; 24.8; 99; 124; 149; 174; 198. Row 5. 4 feet 4 inches, 52; 27.1; 108; 136; 163; 190; 217. Row 6. 4 feet 5 inches, 53; 29.4; 118; 147; 176; 206; 235. Row 7. 4 feet 6 inches, 54; 31.7; 127; 159; 190; 222; 254. Row 8. 4 feet 7 inches. 55; 34; 136; 170; 204; 238; 272. Row 9. 4 feet 8 inches, 56; 36.3; 145; 182; 218; 254; 290. Row 10. 4 feet 9 inches, 57; 38.6; 154; 193; 232; 270; 309. Row 11. 4 feet 10 inches, 58; 40.9; 164; 205; 245; 286; 327. Row 12. 4 feet 11 inches, 59; 43.2; 173; 216; 259; 302; 346. The table shows seven columns: Height in inches, P B W in kilogram, 4 milliliters, 5 milliliters, 6 milliliters, 7 milliliters, and 8 milliliters. Under female, row entries are as follows. Row 13. 5 feet 0 inch, 60; 45.5; 182; 228; 273; 319; 364. Row 14. 5 feet 1 inch, 61; 47.8; 191; 239; 287; 335; 382. Row 15. 5 feet 2 inches, 62; 50.1; 200; 251; 301; 351; 401. Row 16. 5 feet 3 inches, 63; 52.4; 210; 262; 314; 367; 419. Row 17. 5 feet 4 inches, 64; 54.7; 219; 274; 328; 383; 438. Row 18. 5 feet 5 inches, 65; 57; 228; 285; 342; 399; 456. Row 19. 5 feet 6 inches, 66; 59.3; 237; 297; 356; 415; 474. Row 20. 5 feet 7 inches, 67; 61.6; 246; 308; 370; 431; 493. Row 21. 5 feet 8 inches, 68; 63.9; 256; 320; 383; 447; 511. Row 22. 5 feet 9 inches, 69; 66.2; 265; 331; 397; 463; 530. Row 23. 5 feet 10 inches, 70; 68.5; 274; 343; 411; 480; 548. Row 24. 5 feet 11 inches, 71; 70.8; 283; 354; 425; 496; 566. Row 25. 6 feet 0

inch, 72; 73.1; 292; 366; 439; 512; 585. Row 26. 6 feet 1 inch, 73; 75.4; 302; 377; 452; 528; 603. Row 27. 6 feet 2 inches, 74; 77.7; 311; 389; 466; 544; 622. Row 28. 6 feet 3 inches, 75; 80; 320; 400; 480; 560; 640. Row 29. 6 feet 4 inches, 76; 82.3; 329; 412; 494; 576; 658. Row 30. 6 feet 5 inches, 77; 84.6; 338; 423; 508; 592; 677. Row 31. 6 feet 6 inches, 78; 86.9; 348; 435; 521; 608; 695. Row 32. 6 feet 7 inches, 79; 89.2; 357; 446; 535; 624; 714. Row 33. 6 feet 8 inches, 80; 91.5; 366; 458; 549; 641; 732. Row 34. 6 feet 9 inches, 81; 93.8; 375; 469; 563; 657; 750. Row 35. 6 feet 10 inches, 82; 96.1; 384; 481; 577; 673; 769. Row 36. 6 feet 11 inches, 83; 98.4; 394; 492; 590; 689; 787. Row 37. 7 feet 0 inch, 84; 100.7; 403; 504; 604; 705; 806. Under Males, row entries are as follows. Row 1. 4 feet 0 inch, 48; 22.4; 90; 112; 134; 157; 179. Row 2. 4 feet 1 inch, 49; 24.7; 99; 124; 148; 173; 198. Row 3. 4 feet 2 inches, 50; 27; 108; 135; 162; 189; 216. Row 4. 4 feet 3 inches, 51; 29.3; 117; 147; 176; 205; 234. Row 5. 4 feet 4 inches, 52; 31.6; 126; 158; 190; 221; 253. Row 6. 4 feet 5 inches, 53; 33.9; 136; 170; 203; 237; 271. The table shows seven columns: Height in inches, P B W in kilogram, 4 milliliters, 5 milliliters, 6 milliliters, 7 milliliters, and 8 milliliters. Under males, row entries are as follows. Row 7. 4 feet 6 inches, 54; 36.2; 145; 181; 217; 253; 290. Row 8. 4 feet 7 inches, 55; 38.5; 154; 193; 231; 270; 308. Row 9. 4 feet 8 inches, 56; 40.8; 163; 204; 245; 286; 326. Row 10. 4 feet 9 inches, 57; 43.1; 172; 216; 259; 302; 345. Row 11. 4 feet 10 inches, 58; 45.4; 182; 227; 272; 318; 363. Row 12. 4 feet 11 inches, 59; 47.7; 191; 239; 286; 334;

382. Row 13. 5 feet 0 inch, 60; 50; 200; 250; 300; 350; 400. Row 14. 5 feet 1 inch, 61; 52.3; 209; 262; 314; 366; 418. Row 15. 5 feet 2 inches, 62; 54.6; 218; 273; 328; 382; 437. Row 16. 5 feet 3 inches, 63; 56.9; 228; 285; 341; 398; 455. Row 17. 5 feet 4 inches, 64; 59.2; 237; 296; 355; 414; 474. Row 18. 5 feet 5 inches, 65; 61.5; 246; 308; 369; 431; 492. Row 19. 5 feet 6 inches, 66; 63.8; 255; 319; 383; 447; 510. Row 20. 5 feet 7 inches, 67; 66.1; 264; 331; 397; 463; 529. Row 21. 5 feet 8 inches, 68; 68.4; 274; 342; 410; 479; 547. Row 22. 5 feet 9 inches, 69; 70.7; 283; 354; 424; 495; 566. Row 23. 5 feet 10 inches, 70; 73; 292; 365; 438; 511; 584. Row 24. 5 feet 11 inches, 71; 75.3; 301; 377; 452; 527; 602. Row 25. 6 feet 0 inch, 72; 77.6; 310; 388; 466; 543; 621. Row 26. 6 feet 1 inch, 73; 79.9; 320; 400; 479; 559; 639. Row 27. 6 feet 2 inches, 74; 82.2; 329; 411; 493; 575; 658. Row 28. 6 feet 3 inches, 75; 84.5; 338; 423; 507; 592; 676. Row 29. 6 feet 4 inches, 76; 86.8; 347; 434; 521; 608; 694. Row 30. 6 feet 5 inches, 77; 89.1; 356; 446; 535; 624; 713. Row 31. 6 feet 6 inches, 78; 91.4; 366; 457; 548; 640; 731. Row 32. 6 feet 7 inches, 79; 93.7; 375; 469; 562; 656; 750. Row 33. 6 feet 8 inches, 80; 96; 384; 480; 576; 672; 768. Row 34. 6 feet 9 inches, 81; 98.3; 393; 492; 590; 688; 786. Row 35. 6 feet 10 inches, 82; 100.6; 402; 503; 604; 704; 805. Row 36. 6 feet 11 inches, 83; 102.9; 412; 515; 617; 720; 823. Row 37. 7 feet 0 inch, 84; 105.9; 421; 526; 631; 736; 842. Text below the table reads, Abbreviation: P B W, predicted body weight.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 1. Medication: Phenylephrine. Uses: Hypotension, shock; decongestant, O T C nasal spray. Mechanism of Action: Pure alpha adrenergic agonist. Route of Administration: I V, I O. Side Effects: Peripheral vasoconstriction, hypertension, ischemia, reflex bradycardia, low cardiac output, anxiety, restlessness. Special Considerations: Continuous hemodynamic and cardiac monitoring is essential. Administer via central venous access whenever possible; peripheral administration may cause tissue necrosis with extravasation. Vasopressors may worsen myocardial performance in compromised patients. Row 2. Medication: Norepinephrine. Uses: Hypotension, cardiogenic or septic shock, first-line pressor in adult patients with septic shock. Mechanism of Action: Stimulates beta-1 and alpha-1 receptors; increases myocardial contractility and heart rate in addition to systemic vasoconstriction; alpha, vasoconstriction, effects are greater than beta, inotropic and chronotropic, effects. Route of Administration: I V, I O. Side Effects: Peripheral vasoconstriction, hypertension, ischemia, tachycardia, anxiety, restlessness. Special Considerations: Continuous hemodynamic and cardiac monitoring is essential. Administer via central venous access whenever possible; peripheral administration may cause tissue necrosis with extravasation. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special

Considerations. Row entries are as follows. Row 3. Medication: Epinephrine. Uses: Anaphylaxis, hypotension, severe asthma unresponsive to inhaled beta agonists, cardiac arrest, bradycardia unresponsive to atropine or pacing, shock unresponsive to adequate fluid volume replacement, low cardiac output. Mechanism of Action: Stimulation of alpha-1, beta-1, and beta-2 adrenergic receptors, resulting in bronchial smooth muscle relaxation, cardiac inotropy, increased contractility, and chronotropy, increased rate. Route of Administration: Nebulized, subcutaneous, I M, I V, I O, endotracheal tube. Side Effects: Arrhythmias, tachycardias, ventricular ectopy, fibrillation, hypertension, increased myocardial oxygen consumption, vasoconstriction, ischemia, hyperglycemia, nausea, vomiting, anxiety, tremors, nervousness, restlessness. Special Considerations: Continuous hemodynamic and cardiac monitoring is essential. Administer via central venous access whenever possible; peripheral administration may cause tissue necrosis with extravasation. Errors with this agent's use are common, requiring careful dosing and administration, especially in pediatric patients. Row 4. Medication: Vasopressin. Uses: Treatment of hypotension refractory to fluids and catecholamines. Mechanism of Action: Direct systemic vasoconstriction with no inotropic or chronotropic effects through V 1 receptor agonism, non–alpha- or beta-mediated mechanism; additionally decreases urine output and acts as an antidiuretic hormone. Route of Administration: I V, I O. Side Effects: Hypertension, reflex bradycardia, peripheral vasoconstriction, ischemia, decreased urine output. Special Considerations: Continuous hemodynamic and cardiac monitoring is essential. Administer via central venous access whenever possible; peripheral administration may cause tissue necrosis with extravasation. Row 5. Medication: Methylene blue. Uses: Treatment of drug or chemically induced methemoglobinemia, refractory vasoplegia syndrome following cardiac surgery. Mechanism of Action: Speeds conversion of methemoglobin to hemoglobin; may restore vascular tone by direct inhibition of nitric oxides. Route of Administration: I V, I O. Side Effects: Arrhythmias, hypertension, blue skin staining, blue-green fecal discoloration, blue-green urine discoloration, diaphoresis, local ischemia with extravasation. Special Considerations: Continuous hemodynamic and cardiac monitoring is essential. Administer via central venous access whenever possible; peripheral administration may cause tissue necrosis with extravasation. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 6. Medication: Push-dose pressors: epinephrine or phenylephrine. Uses: Emergent treatment of severe hypotension, typically during volume resuscitation or while vasopressor infusions are being prepared. Mechanism of Action: See information for epinephrine or phenylephrine. Route of Administration: I V, I O. Side Effects: See information for epinephrine or phenylephrine. Special Considerations: An arterial line should be in place whenever push-dose pressors are employed owing to significantly increased risks of inducing significant hypertension. Errors are common when admixing; use commercially available products if available. Row 7. Medication: Angiotensin 2. Uses: Septic or distributive shock. Mechanism of Action: Renin-angiotensin-aldosterone system hormone causing vasoconstriction and aldosterone release, increasing blood pressure. Route of Administration: I V, central. Side Effects: Thrombosis, tachycardia, ischemia, delirium. Special Considerations: This vasoactive agent has a unique mechanism of action and is relatively new and costly. It poses considerable risk of thrombosis; all patients must receive prophylactic anticoagulation prior to beginning therapy. Text below the table reads, Abbreviations: c A M P, cyclic adenosine monophosphate; D I, diabetes insipidus; I M, intramuscular; I O, intraosseous; I V, intravenous; O T C, over-the-counter; R O S C, return of spontaneous circulation; S V T, supraventricular tachycardia.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 1. Medication: Dopamine. Uses: Adjunct treatment for cardiogenic shock, hypotension refractory to fluid resuscitation, symptomatic bradycardias unresponsive to atropine or pacing, low cardiac output syndrome. Mechanism of Action: Adrenergic agonist acting on alpha, beta, and dopaminergic receptors to increase contractility and heart rate. Route of Administration: I V, I O. Side Effects: Hypertension, tachycardia, increased myocardial oxygen consumption, peripheral vasoconstriction, ischemia, anxiety, nervousness, restlessness. Special Considerations: Continuous hemodynamic and cardiac monitoring is essential. Administer via central venous access whenever possible; peripheral administration may cause tissue necrosis with extravasation. Dopamine impairs renal, gastrointestinal, and hepatic perfusion, and impairs respiratory, immune, and endocrine function. Row 2. Medication: Dobutamine. Uses: Short-term management of depressed cardiac output in patients with heart failure, management of sepsis-induced myocardial dysfunction. Mechanism of Action: Stimulates myocardial beta receptors to increase heart rate and contractility; stimulates beta-1, beta-2, and alpha receptors in vasculature; the greater beta effects result in vasodilation. Route of Administration: I V, I O. Side Effects: Arrhythmias, dobutamine leads to more tachycardia than dopamine, hypotension, ischemia. Special Considerations: Continuous hemodynamic and cardiac monitoring is essential. Administer via central venous access whenever possible; peripheral administration may cause tissue necrosis with extravasation. Row 3. Medication: Milrinone. Uses: Short-term treatment for acutely decompensated heart failure; typically used in patients unresponsive to dobutamine or patients intolerant of dobutamine-induced tachyarrhythmias. Mechanism of Action:

Selective phosphodiesterase inhibitor with inotropic and vasodilatory effects; minimal to no chronotropic activity. Route of Administration: I V infusion, loading infusion may be given initially. Side Effects: Hypotension, arrhythmias, headache. Special Considerations: Continuous hemodynamic and cardiac monitoring is essential. When initiated without a loading dose, significant effects will be seen in 30 minutes and peak in 2 to 3 hours. Increased pressor requirements after 24 hours of therapy may signal the need for milrinone weaning. Text below the table reads, Abbreviations: A V, atrioventricular; I O, intraosseous; I V, intravenous.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 1. Medication: Sodium nitroprusside. Uses: Hypertensive crisis management, acute decompensated heart failure. Mechanism of Action: Direct action on arterial and venous smooth muscles; increases cardiac output by lowering afterload. Route of Administration: I V or I O infusion. Side Effects: Hypotension, flushing, tachycardia, methemoglobinemia, metabolic acidosis, secondary to cyanide toxicity, hyperreflexia, secondary to thiocyanate toxicity, headache, light-headedness, dizziness, syncope. Special Considerations: Thiocyanate and cyanide toxicity are possible, especially with prolonged or high-dose infusions. Continuous blood pressure monitoring with an arterial line is mandatory. Monitor vital signs, acid–base status, and thiocyanate levels during prolonged treatment. Protect the prepared solution from light. The solution should be clear to brown in color; near-complete decomposition in light results in blue discoloration. Row 2. Medication: Nitroglycerin. Uses: Treatment or prevention of angina, acute decompensated heart failure, vasopressor extravasation injury. Mechanism of Action: Forms a nitric oxide free radical that acts directly on vascular smooth muscle to produce vasodilation; effects are greater on venous than arterial vessels. Route of Administration: Sublingual, transdermal, I V, I O. Side Effects: Hypotension, flushing, tachycardia, headache, light-headedness, dizziness, syncope. Special Considerations: Monitor vital signs during infusion. Because adsorption occurs with soft plastics, nonpolyvinyl chloride tubing should be used. Row 3. Medication: Hydralazine. Uses: Hypertension, heart failure with intolerance to A C E Is or A R Bs, postoperative hypertension, hypertensive emergencies during pregnancy. Mechanism of Action: Causes direct dilation of arterial wall smooth muscle. Route of Administration: Oral, I M, I V, I O. Side Effects: Tachycardia, hypotension, rebound hypertension, flushing, nausea, vomiting, edema. Special Considerations: Monitor blood pressure and heart rate before and after administration. Onset of action with I V administration is 5 to 20 minutes and lasts for 1 to 4 hours, although hypotension may last longer. Expect an increased heart rate. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 4. Medication: Clevidipine. Uses: Hypertension. Mechanism of Action: Calcium channel blocker with potent arterial-vasodilating activity. Route of Administration: I V or I O infusion only. Side Effects: Atrial fibrillation, fever, nausea, headache, insomnia. Special Considerations: Formulated in an oil-water lipid emulsion; change the tubing every 12 hours. Continuously monitor blood pressure during infusion. Vials and tubing resemble those for propofol, requiring caution during simultaneous infusion, both are milky-white liquids. Row 5. Medication: Nicardipine. Uses: Hypertension, hypertension during acute ischemic stroke. Mechanism of Action: Calcium channel blocker with direct action on arterial and coronary vascular smooth muscle; vasodilates and increases myocardial oxygen delivery in vasospastic angina. Route of Administration: I V, I O. Side Effects: Hypotension, flushing, headache, dizziness, edema, dose related, palpitations, tachycardia, bradycardia. Special Considerations: Continuously monitor blood pressure and heart rate during infusion. Closely monitor infusion site; administer via central line if possible; change peripheral IV sites every 12 hours. Text below the table reads, Abbreviations: A C E I, angiotensin-converting enzyme inhibitor; A R B, angiotensin 2 receptor blocker; I M, intramuscular; I O, intraosseous; I V, intravenous.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Under head Sedatives, row entries are as follows. Row 1. Medication: Midazolam. Uses: Sedation, anxiety, amnesia, during procedures, for induction of general anesthesia, seizures. Mechanism of Action: Enhances the action of the inhibitory neurotransmitter G A B A. Route of Administration: Oral, I V, I O, I M, intranasal, buccal. Side Effects: Respiratory depression, hypotension, drowsiness, nausea, vomiting. Special Considerations: Due to its low p H of 3, burning is likely to occur with intranasal administration. Higher concentrations, that is, 5 milligrams per milliliter, are preferred to reduce the total intranasal volume needed. Monitor respiratory status using capnography as well as blood pressure during administration. Row 2. Medication: Diazepam. Uses: Anxiety, acute alcohol withdrawal, muscle spasm, seizures, sedation. Mechanism of Action: Enhances the action of the inhibitory neurotransmitter G A B A. Route of Administration: Oral, I V, I O, I M, rectal. Side Effects: Hypotension, drowsiness, respiratory depression, localized phlebitis, pain at injection site. Special Considerations: Diazepam is a vesicant; avoid extravasation. Monitor respiratory status using capnography as well as blood pressure during administration. Row 3. Medication: Lorazepam. Uses: Anxiety, amnesia, agitation, premedication to general anesthesia, alcohol withdrawal syndrome, seizures, chemotherapy-associated nausea and vomiting. Mechanism of Action: Enhances the action of the inhibitory neurotransmitter G A B A. Route of Administration: Oral, S L, I V, I O, I M. Side Effects: Hypotension, sedation, respiratory depression. Special Considerations: Unopened vials require refrigeration, contact the manufacturer for room-temperature storage information. The injectable solution requires dilution. Its thickness also makes it difficult to withdraw from vial; use larger-gauge needles. Contains propylene glycol or benzyl alcohol; long-term or high-dose infusions may lead to toxicity. Monitor respiratory status using capnography as well as blood pressure during administration. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 4. Medication: Phenobarbital. Uses: Seizures, sedation, alcohol and sedative-hypnotic withdrawal, status epilepticus. Mechanism of Action: Depresses the sensory cortex, which slows cerebral metabolism and decreases cerebral oxygen consumption. Route of Administration: Oral, I M, I V, I O. Side Effects: Bradycardia, hypotension, syncope, profound C N S depression, respiratory depression. Special Considerations: Monitor heart rate, blood pressure, oxygen saturation, and capnography continuously during administration. Row 5. Medication: Dexmedetomidine. Uses: I C U sedation of mechanically ventilated patients, procedural sedation of nonintubated patients. Mechanism of Action: Agonist of alpha-2 adrenergic receptors; exhibits both sedative and anesthetic properties. Route of Administration: I V. Side Effects: Sedation, hypotension, bradycardia, risk related to loading doses or higher maintenance doses, agitation and delirium, responds well to benzodiazepines, inhibits salivation. Special Considerations: Patients are usually readily aroused with stimulation. Dexmedetomidine is not appropriate for patients who are paralyzed. Monitor heart rate and blood pressure continuously during administration. Use narcotics and benzodiazepines cautiously and in reduced doses; dexmedetomidine enhances their effects. Under head Anesthetics, row entries are as follows. Row 6. Medication: Propofol. Uses: Induction of anesthesia, procedural sedation, refractory status epilepticus. Mechanism of Action: Causes global C N S depression through likely agonism of G A B A-1 receptors. Route of Administration: I V, I O. Side Effects: Hypotension, injection-site burning and pain, apnea, arrhythmias, hypertriglyceridemia with high-dose, long-term infusion, more than 2 days, oversedation, propofol-related infusion syndrome. Special Considerations: Monitor heart rate, blood pressure, oxygen saturation, and capnography continuously during administration. Lidocaine may be used to reduce injection-site pain. Requires aseptic handling; the lipid emulsion encourages bacterial growth. Change tubing every 12 hours. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 7. Medication: Etomidate. Uses: Induction of anesthesia, procedural sedation. Mechanism of Action: Ultra-short-acting benzylimidazole general anesthetic. Route of Administration:

I V, I O. Side Effects: Pain at injection site, nausea and vomiting on emergence from anesthetic effects, myoclonus, up to 33 percent of patients, transient skeletal movements, uncontrolled eye movements, hiccups, apnea, impaired cortisol synthesis. Special Considerations: Monitor heart rate, blood pressure, oxygen saturation, and capnography continuously during administration. Monitor the infusion site carefully; etomidate is very irritating. Row 8. Medication: Ketamine. Uses: Induction and maintenance of general anesthesia, analgesia, procedural sedation, refractory status epilepticus. Mechanism of Action: Produces a cataleptic-like state, dissociation, most likely by N M D A receptor antagonism. Route of Administration: I V, I O, I M, oral. Side Effects: Hypertension and increased heart rate, transient; may cause auditory and visual hallucinations, restlessness, vivid dreams, irrational behavior on emergence; tonic-clonic movements resembling seizure. Special Considerations: Laryngeal reflexes and respiratory drive usually remain intact during ketamine administration. Bronchodilation occurs. Monitor heart rate, blood pressure, oxygen saturation, and capnography continuously during administration. Laryngospasm is an extremely rare but dangerous side effect. Under head Antipsychotics, row entries are as follows. Row 9. Medication: Haloperidol. Uses: Behavioral disorders, delirium, tranquilization of agitated or aggressive or violent patients. Mechanism of Action: Blocks postsynaptic dopaminergic D 2 receptors; first-generation, typical, antipsychotic. Route of Administration: Oral, I M, I V, I O, I V is common but unapproved. Side Effects: Q T prolongation, especially at high I V doses, excessive sedation, hypotension, bradycardia, neuroleptic malignant syndrome, and extrapyramidal symptoms. Special Considerations: Avoid large doses. Monitor blood pressure and cardiac rhythm. Baseline 12-lead E C G recommended to follow Q T c. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 10. Medication: Olanzapine. Uses: Treatment of schizophrenia-associated acute agitation, delirium, psychosis or acute agitation, P T S D, Tourette syndrome. Mechanism of Action: Combined antagonism of dopamine and serotonin receptor sites; atypical antipsychotic. Route of Administration: I M, oral, O D T available. Side Effects: Orthostatic hypotension, drowsiness, Parkinson-like syndrome, extrapyramidal syndrome, weight gain, with regular use. Special Considerations: Patients should be monitored closely for excessive sedation. Row 11. Medication: Quetiapine. Uses: Delirium in the critically ill patient, generalized anxiety disorder, bipolar disorder, schizophrenia. Mechanism of Action: Believed to be a combination of dopamine and serotonin receptor antagonism; atypical antipsychotic. Route of Administration: Oral. Side Effects: Drowsiness, dry mouth, xerostomia, orthostatic hypotension. Special Considerations: Lack of parenteral formulation may be challenging in noncooperative patients. Under head Analgesics, row entries are as follows.

Row 12. Medication: Fentanyl. Uses: Pain management, adjunct to anesthesia. Mechanism of Action: Binds with opioid receptors in the C N S, preventing painful impulse transmission. Route of Administration: Oral, transdermal, I M, I V, I O, intranasal. Side Effects: Respiratory depression, apnea, hypotension, bradycardia, palpitations, flushing, nausea, vomiting, constipation, disorientation, urinary retention. Special Considerations: Monitor heart rate, blood pressure, oxygen saturation, and capnography continuously during administration. Row 13. Medication: Sufentanil. Uses: Pain management, adjunct to anesthesia, surgical and postoperative analgesia. Mechanism of Action: Binds with opioid receptors in the C N S, preventing painful impulse transmission. Route of Administration: I V, I O, S L. Side Effects: Respiratory depression, apnea, hypotension, bradycardia, palpitations, flushing, nausea. Special Considerations: Considerably more potent and shorter acting than fentanyl. Monitor heart rate, blood pressure, oxygen saturation, and capnography continuously during administration. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 14. Medication: Morphine. Uses: Pain management. Mechanism of Action: Binds with opioid receptors in the C N S, preventing painful impulse transmission. Route of Administration: Oral, subcutaneous, I M, I V, I O, intranasal. Side Effects: Respiratory depression, apnea, hypotension, bradycardia, palpitations, flushing, nausea and vomiting, usually related to speed of administration, urinary retention, constipation. Special Considerations: Monitor heart rate, blood pressure, oxygen saturation, and capnography continuously during administration. Use with caution in patients with renal dysfunction, may accumulate. Row 15. Medication: Hydromorphone. Uses: Pain management. Mechanism of Action: Binds with opioid receptors in the C N S, preventing painful impulse transmission; produces generalized C N S depression. Route of Administration: Oral, subcutaneous, I M, I V, I O, P R. Side Effects: Respiratory depression, apnea, hypotension, bradycardia, palpitations, flushing, nausea, vomiting, abnormal dreams, cognitive dysfunction. Special Considerations: Often used in patients who are allergic to or who fail to respond to morphine. Use with caution because of its potency. Monitor heart rate, blood pressure, oxygen saturation, and capnography continuously during administration. Row 16. Medication: Nalbuphine. Uses: Pain management, opioid-induced pruritus, itching. Mechanism of Action: Agonist and partial antagonist; binds with opioid receptors in the C N S. Route of Administration: Subcutaneous, I M, I V, I O. Side Effects: Excessive sedation, respiratory depression, dizziness, nausea, vomiting. Special Considerations: Often used for opioid-induced pruritus, especially with epidural opioid infusions. Blood pressure and respiratory monitoring are recommended when nalbuphine is used for analgesia. Row 17. Medication: Acetaminophen. Uses: Temporary relief of minor aches and pains, mild to moderate pain, antipyretic, treatment of moderate to severe pain when combined with an opioid. Mechanism of Action: Believed to activate serotonergic inhibitory pathways; works peripherally to block pain impulses; antipyresis results from inhibition of heat-regulating hypothalamic centers. Route of Administration: Oral, P R, I V, I O. Side Effects: Most significant side effect is liver toxicity; maximum daily dose for healthy adults is 4 grams; limit to less than 2 grams per day for patients with liver disease or E t O H abuse history. Special Considerations: Often combined with opioids for treatment of severe pain. Use caution with total daily dose when giving combination products and acetaminophen. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 18. Medication: Ketorolac. Uses: Short-term, less than 5 days, management of moderate to severe pain, treatment of migraine in adults. Mechanism of Action: Inhibits C O X-1 and C O X-2 enzymes, decreasing formation of prostaglandin precursors; exhibits antipyretic, analgesic, and anti-inflammatory properties. Route of Administration: Oral, I M, I V, I O. Side Effects: Abdominal discomfort, gastritis, headache, renal insufficiency. Special Considerations: Use with caution in patients with preexisting renal dysfunction. Ketorolac inhibits platelet function and is contraindicated in patients at high risk of bleeding. Administer I V doses slowly, over more than 15 seconds. Under head Anticonvulsants, row entries are as follows. Row 19. Medication: Levetiracetam. Uses: Seizures, status epilepticus, seizure prophylaxis in patients with subarachnoid hemorrhage. Mechanism of Action: Unknown; believed to have multiple central pharmacologic effects, including calcium channel and facilitation of G A B A inhibitory transmission. Route of Administration: Oral, I V, I O. Side Effects: Behavioral problems and vomiting in children and adolescents, weakness, C N S depression. Special Considerations: Administer I V doses over 15 minutes or at a rate of 2 to 5 milligrams per kilogram per minute. Row 20. Medication: Phenytoin. Uses: Seizures, status epilepticus, prevention of early, within 1 week, seizures following traumatic brain injury. Mechanism of Action: Decreases cellular sodium levels in the motor cortex of the C N S; increases effective refractory period in neural cells; also has antiarrhythmic activity. Route of Administration: Oral, I V, I O. Side Effects: Hypotension, C N S depression, nausea, cardiac arrhythmias, venous irritation, skin rash. Special Considerations: I V phenytoin should not be infused any faster than 50 milligrams per minute in adults. Slow the infusion rate if hypotension occurs. Monitor I V sites closely for signs of infiltration; phenytoin is a vesicant. Row 21. Medication: Fosphenytoin. Uses: Seizures, status epilepticus. Mechanism of Action: Stabilizes neuronal membranes and influx and efflux of sodium across cell membranes. Route of Administration: I M, I V, I O. Side Effects: Hypotension, C N S depression, cardiac arrhythmias, venous irritation; transient and dose-related pruritus, tinnitus, and somnolence. Special Considerations: I V fosphenytoin is considered safer for administration than phenytoin. Monitor I V sites closely for signs of infiltration. Continuous respiratory, blood pressure, and E C G monitoring are recommended during loading doses and for 10 to 20 minutes after infusion. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 22. Medication: Valproic acid. Uses: Seizures, status epilepticus, bipolar disorder. Mechanism of Action: Increases G A B A availability. Route of Administration: Oral, I V, I O. Side Effects: Headache, drowsiness, gastrointestinal distress, dose-related thrombocytopenia, tremor, weakness, visual disturbances. Special Considerations: Monitor liver function, platelets, prothrombin time and partial thromboplastin time, and serum ammonia levels during therapy. Row 23. Medication: Pentobarbital. Uses: Sedation, status epilepticus refractory to first-line anticonvulsants, barbiturate coma in severe brain injury with elevated intracranial pressure. Mechanism of Action: Depresses the sensory cortex, which slows cerebral metabolism and decreases cerebral oxygen consumption. Route of Administration: I M, I V, I O. Side Effects: Bradycardia, hypotension, syncope, profound C N S depression, respiratory depression, nausea, vomiting. Special Considerations: Monitor heart rate, blood pressure, oxygen saturation, and capnography continuously during administration. Text below the table reads, Abbreviations: C

N S, central nervous system; C O X-1, cyclooxygenase 1; C O X-2, cyclooxygenase 2; E C G, electrocardiogram; E t O H, ethyl alcohol; G A B A, gamma-aminobutyric acid; I C U, intensive care unit; I M, intramuscular; I O, intraosseous; I V, intravenous; N M D A, N-methyl-d-aspartate; O D T, oral disintegrating tablets; P R, rectal; P T S D, posttraumatic stress disorder; S L, sublingual.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 1. Medication: Succinylcholine. Uses: Fast-acting depolarizing N M B A, facilitation of tracheal intubation. Mechanism of Action: Similar to acetylcholine: depolarizes motor endplates at myoneural junction, leading to sustained flaccid paralysis. Route of Administration: I V, I O, I M. Side Effects: Hypertension, hypotension, bradycardia, tachycardia, excessive salivation, muscle fasciculations, hyperkalemia, increased intraocular pressure, malignant hyperthermia, apnea. Special Considerations: Monitor E C G, blood pressure, pulse oximetry, waveform capnography, temperature, and neuromuscular function, with a peripheral nerve stimulator, during treatment. Monitor serum potassium prior to and during treatment. Row 2. Medication: Pancuronium. Uses: Long-acting N M B A, to facilitate tracheal intubation, skeletal muscle relaxant during surgery or mechanical ventilation. Mechanism of Action: Blocks acetylcholine from binding to motor endplate receptors, nondepolarizing, inhibiting depolarization. Route of Administration: I V, I O. Side Effects: Vagolytic, more than 90 percent of patients have H R increase of more than 10 beats per minute; use cautiously in patients who cannot tolerate increased H R. Clearance prolonged in patients with renal and liver failure. Special Considerations: Monitor E C G, blood pressure, pulse oximetry, waveform capnography, temperature, and neuromuscular function, with a peripheral nerve stimulator, during treatment. Row 3. Medication: Vecuronium. Uses: Intermediate-acting N M B A, to facilitate tracheal intubation, skeletal muscle relaxant during surgery or mechanical ventilation. Mechanism of Action: Blocks acetylcholine from binding to motor endplate receptors, nondepolarizing, inhibiting depolarization. Route of Administration: I V, I O. Side Effects: Is not vagolytic, like pancuronium; lower doses needed in patients with renal and hepatic insufficiency, 30 percent is renally excreted, 50 percent excreted in feces. Special Considerations: Monitor E C G, blood pressure, pulse oximetry, waveform capnography, temperature, and neuromuscular function, with a peripheral nerve stimulator, during treatment. Row 4. Medication: Rocuronium. Uses: Intermediate-acting N M B A, to facilitate tracheal intubation, skeletal muscle relaxant during surgery or mechanical ventilation. Mechanism of Action: Blocks acetylcholine from binding to motor endplate receptors, nondepolarizing, inhibiting depolarization. Route of Administration: I V, I O. Side Effects: Very rapid onset of action, less than 2 minutes. Special Considerations: Monitor E C G, blood pressure, pulse oximetry, waveform capnography, temperature, and neuromuscular function, with a peripheral nerve stimulator, during treatment. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 5. Medication: Atracurium. Uses: Intermediate-acting N M B A, to facilitate tracheal intubation, skeletal muscle relaxant during surgery or mechanical ventilation. Mechanism of Action: Blocks acetylcholine from binding to motor endplate receptors, nondepolarizing, inhibiting depolarization. Route of Administration: I V, I O. Side Effects: Minimal cardiovascular adverse effects but is associated with histamine release at higher doses, flushing, hives, pruritus, wheezing; potential for C N S excitation, especially with higher doses. Special Considerations: Monitor E C G, blood pressure, pulse oximetry, waveform capnography, temperature, and neuromuscular function, with a peripheral nerve stimulator, during treatment. Row 6. Medication: Cisatracurium. Uses: Intermediate-acting N M B A, to facilitate tracheal intubation, skeletal muscle relaxant during surgery or mechanical ventilation. Mechanism of Action: Blocks acetylcholine from binding to motor endplate receptors, nondepolarizing, inhibiting depolarization. Route of Administration: I V, I O. Side Effects: Fewer cardiovascular effects; less tendency than atracurium for histamine release. Special Considerations: Monitor E C G, blood pressure, pulse oximetry, waveform capnography, temperature, and neuromuscular function, with a peripheral nerve stimulator, during treatment. Text below the table reads, Abbreviations: C N S, central nervous system; E C G, electrocardiogram; H R, heart rate; I M, intramuscular; I O, intraosseous; I V, intravenous; N M B A, neuromuscular-blocking agent.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Under head H 2 Blocker Medications, row entries are as follows. Row 1. Medication: Famotidine. Uses: Gastric acid reduction in patients with ulcers, reflux, or excessive gastric secretions; adjunct to H 1 blockers in patients with allergic or anaphylactic reactions. Mechanism of Action: Inhibition of H 2 receptors, in gastric parietal cells, which release gastric acids. Route of Administration: Oral, I V, I O. Side Effects: Agitation and vomiting in pediatric patients; confusion, delirium, vomiting, headache, dizziness, diarrhea, constipation. Special Considerations: I V doses should be given over at least 2 minutes. Dose reduction is needed in patients with renal insufficiency. Row 2. Medication: Cimetidine. Uses: Gastric acid reduction in patients with ulcers, reflux, or excessive gastric secretions; adjunct to H 1 blockers in patients with allergic or anaphylactic reactions. Mechanism of Action: Inhibition of H 2 receptors, in cells that release gastric acids. Route of Administration: Oral. Side Effects: Headache, dizziness, diarrhea, confusion, delirium. Special Considerations: Dosing adjustment is needed in patients with renal insufficiency. Significant drug interactions exist. Under head Proton Pump Inhibitors, row entries are as follows. Row 3. Medication: Esomeprazole. Uses: Gastric acid reduction in patients with ulcers, reflux, or excessive gastric secretions; reduction of postprocedure risk for ulcer rebleeding. Mechanism of Action: Suppresses gastric acid secretion by inhibiting hydrogen and potassium A T Pase enzyme, proton pump, on gastric parietal cells. Route of Administration: Oral, I V, I O. Side Effects: Headache, dizziness, flatulence, diarrhea, abdominal pain, nausea, constipation. Special Considerations: Administer I V doses over more than 3 minutes. Row 4. Medication: Pantoprazole. Uses: Gastric acid reduction in patients with ulcers, reflux, or excessive gastric secretions; reduction of postprocedure risk for rebleeding. Mechanism of Action: Suppresses gastric acid secretion by inhibiting hydrogen and potassium A T Pase enzyme, proton pump, on gastric parietal cells. Route of Administration: Oral, I V, I O. Side Effects: Headache, dizziness, edema, diarrhea, abdominal pain. Special Considerations: Administer I V doses over at least 2 minutes. Text below the table reads, Abbreviations: A T Pase, adenosine triphosphatase; H 1, histamine 1; H 2, histamine 2; I M, intramuscular; I O, intraosseous; I V, intravenous.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Under head Dopamine Antagonists, row entries are as follows. Row 1. Medication: Promethazine. Uses: Prevention and control of nausea and vomiting, treatment of motion sickness, procedural sedation. Mechanism of Action: Blocks dopamine receptors in the cerebral medulla; has some antihistamine properties that also suppress nausea and vomiting. Route of Administration: Oral, P R, I V, I O, I M. Side Effects: Hypotension, hypertension, bradycardia, tachycardia, sedation, akathisia, intense feeling of restlessness and anxiety, extrapyramidal symptoms, neuroleptic malignant syndrome, seizures, delirium, disorientation. Special Considerations: Monitor for C N S effects. Be cautious with I V administration: Promethazine is a vesicant and can cause serious tissue injury, including gangrene, and has resulted in limb amputations. Row 2. Medication: Prochlorperazine. Uses: Management of severe nausea and vomiting, termination of migraines. Mechanism of Action: Blocks dopamine receptors in the cerebral medulla; believed to also depress the reticular activating system. Route of Administration: Oral, P R, I V, I O, I M. Side Effects: Hypotension, hypertension, bradycardia, tachycardia, sedation, akathisia, extrapyramidal symptoms, neuroleptic malignant syndrome, seizures, delirium, disorientation. Special Considerations: Administer I V doses slowly, not exceeding 5 milligrams per minute. Row 3. Medication: Metoclopramide. Uses: Gastroparesis, prevention of nausea and vomiting; G E R D. Mechanism of Action: Blocks dopamine receptors in the cerebral medulla; at higher doses, also blocks serotonin receptors in the C N S chemoreceptor trigger zone. Route of Administration: Oral, I M, I V, I O. Side Effects: Hypotension, hypertension, bradycardia, tachycardia, sedation, akathisia, extrapyramidal symptoms, neuroleptic malignant syndrome. Special Considerations: While the manufacturer advises administration of doses 10 milligrams or less over 1 to 2 minutes, rapid administration may cause akathisia. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Under head Other, row entries are as follows. Row 4. Medication: Ondansetron. Uses: Prevention of nausea and vomiting. Mechanism of Action: Selectively blocks serotonin receptors both peripherally, vagal nerve terminals, and centrally, chemoreceptor trigger zone. Route of Administration: Oral, I M, I V, I O, O D T. Side Effects: Headache, drowsiness, fatigue, dizziness, constipation; dose-dependent Q T prolongation. Special Considerations: Theoretically, works best before vomiting starts. Administer I V doses over at least 30 seconds, preferably over 2 to 5 minutes. Row 5. Medication: Octreotide. Uses: Gastroesophageal variceal hemorrhage, certain tumors, chemotherapy-associated diarrhea. Mechanism of Action: Mimics endogenous somatostatin: decreases intestinal fluid secretion, gastrointestinal motility, and portal blood flow. Route of Administration: Subcutaneous, I M, I V. Side

Effects: Vary by dose and route of administration. Special Considerations: Potential for Q T prolongation, which may be enhanced with vasoconstrictors. Consider obtaining a baseline 12-lead E C G to monitor Q T. May also be used for treatment of oral sulfonylurea overdose. Row 6. Medication: Droperidol. Uses: Prevention and treatment of nausea and vomiting from surgical or diagnostic procedures. Mechanism of Action: Blocks dopamine stimulation in the chemoreceptor trigger zone. Route of Administration: I M, I V, I O. Side Effects: Dose-dependent Q T prolongation, dizziness, drowsiness, extrapyramidal symptoms, restlessness. Special Considerations: Obtaining a baseline 12-lead E C G is recommended to follow Q T intervals. Cardiac monitoring is recommended. Text below the table reads, Abbreviations: C N S, central nervous system; E C G, electrocardiogram; G E R D, gastroesophageal reflux disease; I M, intramuscular; I O, intraosseous; I V, intravenous; O D T, orally disinte-grating tablet; P R, per rectum.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 1. Medication: Epoprostenol. Uses: Treatment of pulmonary arterial hypertension. Mechanism of Action: Direct vasodilation of pulmonary and systemic arterial vascular beds; inhibits platelet aggregation. Route of Administration: Continuous jet nebulizer, I V. Side Effects: Flushing, headaches, nausea, vomiting, hypotension, tachycardia. Special Considerations: Must be infused through a central line; temporary peripheral infusion is permitted while central access is obtained. Requires special tubing. Do not interrupt the infusion. Avoid bolus injections. Carefully monitor blood pressure. Row 2. Medication: Alprostadil. Uses: Temporary maintenance of patent ductus arteriosus in neonates with ductal-dependent congenital heart lesions until surgical repair, pulmonary hypertension in children with congenital heart defects and left-to-right shunts. Mechanism of Action: Prostaglandin, which causes direct relaxation of ductus arteriosus and vascular smooth muscle. Route of Administration: I V. Side Effects: Apnea, flushing, fever, bradycardia, tachycardia, hypotension, hypertension. Special Considerations: Anticipate more than a 10 percent chance of apnea. Carefully monitor respirations. Row 3. Medication: Aerosolized epinephrine. Uses: Treatment of bronchospasm associated with bronchial asthma, croup, stridor. Mechanism of Action: Alpha and beta bronchial tree smooth muscle stimulation, promotes relaxation. Route of Administration: Nebulized. Side Effects: Tachycardia, hypertension. Special Considerations: Monitor heart rate and respiratory status. Text below the table reads, Abbreviations: I O, intraosseous; I V, intravenous.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special

Considerations. Under head Class 1 Antiarrhythmic Medications, row entries are as follows. Row 1. Medication: Procainamide. Uses: Treatment of various atrial or ventricular arrhythmias, different class 1 agents are appropriate for different types of arrhythmias. Mechanism of Action: Blocks fast sodium channels; inhibits depolarization of neuronal cells; decreases myocardial conduction velocity and automaticity. Route of Administration: I V. Side Effects: Hypotension, nausea, vomiting, unwanted conduction disturbances. Special Considerations: Monitor E C G, blood pressure, and renal function. Row 2. Medication: Lidocaine. Uses: Treatment of ventricular arrhythmias, different class 1 agents are appropriate for different types of arrhythmias. Mechanism of Action: Blocks fast sodium channels; inhibits depolarization of neuronal cells; decreases myocardial conduction velocity and automaticity. Route of Administration: I V. Side Effects: Hypotension, nausea, vomiting, seizures, altered mental status. Special Considerations: Monitor E C G and C N S status. As with amiodarone, considered a first-line agent in patients with ventricular fibrillation or pulseless ventricular tachycardia. Row 3. Medication: Flecainide. Uses: Treatment and prevention of atrial fibrillation and flutter, P S V T, and ventricular arrhythmias. Mechanism of Action: Slows conduction in cardiac tissue by altering ion transport across cell membranes. Route of Administration: P O. Side Effects: Dizziness, visual disturbances, dyspnea. Special Considerations: Monitor E C G and blood pressure during administration. Proarrhythmic effects including ventricular fibrillation and tachycardia have been reported with use in patients with atrial fibrillation. Under head Class 2 Antiarrhythmic Medications, row entries are as follows. Row 4. Medication: Labetalol. Uses: Treatment of mild to severe hypertension. Mechanism of Action: Competitively blocks beta receptors in heart, blood vessels; also blocks alpha-1 receptors; may affect other beta receptors at higher doses. Route of Administration: Oral, I V. Side Effects: Hypotension, bradycardia, conduction abnormalities, dizziness, hypoglycemia. Special Considerations: A loss of beta selectivity occurs following high doses or overdose. May exacerbate bronchospasm in patients with reactive airway disease. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 5. Medication: Metoprolol. Uses: Treatment of hypertension, rate control in atrial fibrillation, tremors, certain psychological disorders, migraines. Mechanism of Action: Selectively inhibits beta-1 receptors; little to no effect on beta-2 receptors at doses less than 100 milligrams per day in adults. Route of Administration: Oral, I V. Side Effects: Hypotension, bradycardia, conduction abnormalities, dizziness. Special Considerations: Avoid use in patients with cocaine toxicity due to theoretical risk of unopposed alpha stimulation. A loss of beta selectivity occurs following high doses or overdose. Row 6. Medication: Esmolol. Uses: Treatment of S V T and control of ventricular rate in atrial fibrillation and flutter; treatment of tachycardia and hypertension. Mechanism of Action: Competitively blocks beta-1 receptors; little to no effect on beta-2 receptors except at high doses. Route of Administration: I V. Side Effects: Hypotension, bradycardia, infusion-site reactions. Special Considerations: Use cautiously in heart block greater than first degree. Usually given as an infusion, with an optional bolus prior to start of therapy. Row 7. Medication: Sotalol. Uses: Treatment of life-threatening ventricular arrhythmias; maintenance of sinus rhythm in patients with symptomatic atrial fibrillation and flutter. Mechanism of Action: Both beta blocking and cardiac action potential duration-prolonging effects. Route of Administration: Oral, I V. Side Effects: Bradycardia, chest pain, palpitations, fatigue; dose-related proarrhythmias such as torsades de pointes. Special Considerations: Contraindicated if baseline Q T c greater than 450 milliseconds, serum potassium less than 4 milliequivalents per liter, or creatinine clearance less than 40 milliliters per minute. Monitor Q T c during therapy. Under head Class 3 Antiarrhythmic Medications, row entries are as follows. Row 8. Medication: Amiodarone. Uses: Management of life-threatening ventricular arrhythmias, atrial fibrillation in critically ill patients or patients with heart failure, S V T, maintenance of sinus rhythm after conversion of atrial fibrillation. Mechanism of Action: Inhibits alpha and beta stimulation; blocks sodium, potassium, and calcium channels; decreases A V conduction and sinus node function. Route of Administration: Oral, I V, I O. Side Effects: Q T-interval prolongation, infusion rate; related hypotension, bradycardia, other conduction abnormalities, flushing, edema, hypothyroidism, pulmonary toxicity. Special Considerations: Monitor E C G and blood pressure during administration. Central line administration is preferred to decrease the incidence of phlebitis. Long-term effects can be significant, including pulmonary toxicity, hypothyroidism, corneal deposits with visual changes, and abnormal liver function tests. Like lidocaine, considered a first-line agent in patients with ventricular fibrillation or pulseless ventricular tachycardia. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Under head Class 4 Antiarrhythmic Medications, row entries are as follows. Row 9. Medication: Verapamil. Uses: S V T; oral administration is used for hypertension. Mechanism of Action: Blocks slow calcium channels, especially in the S A and A V nodes; inhibits calcium influx into cells in arterial walls, decreasing systemic vascular resistance. Route of Administration: Oral, I V, I O. Side Effects: Hypotension, bradycardia, conduction disturbances, edema, flushing. Special Considerations: Monitor blood pressure and E C G during administration. Verapamil is a nondihydropyridine calcium channel blocker and should be used cautiously in patients with heart failure. Row 10. Medication: Diltiazem. Uses: Rate control of narrow-complex tachycardias; vasopressor medications induce vasoconstriction, which in turn elevates mean arterial blood pressure, S V T, and atrial fibrillation; oral administration is used for hypertension. Mechanism of

Action: Blocks slow calcium channels, especially in the S A and A V nodes; inhibits calcium influx into cells in arterial walls, decreasing systemic vascular resistance. Route of Administration: Oral, I V, I O. Side Effects: Hypotension, bradycardia, conduction disturbances, edema, flushing. Special Considerations: Monitor blood pressure and E C G during administration. Diltiazem is a nondihydropyridine calcium channel blocker and should be used cautiously in patients with heart failure. Text below the table reads, Abbreviations: A V, atrioventricular; C N S, central nervous system; E C G, electrocardiogram; I O, intraosseous; I V, intravenous; P S V T, paroxysmal supraventricular tachycardia; Q T c, corrected Q T; S A, sinoatrial; S V T, supraventricular tachycardia.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 1. Medication: Heparin. Uses: Anticoagulation, prophylaxis and treatment of thromboembolic disorders, adjunct to fibrinolysis in S T E M I, D V T, and P E prophylaxis and treatment in critically ill patients. Mechanism of Action: Impairs blood fibrin formation by inactivating thrombin as well as other coagulation factors. Route of Administration: Subcutaneous, I V. Side Effects: Thrombocytopenia, bleeding. Special Considerations: Monitor a P T T during administration of heparin infusions and following I V bolus injections. Adjust doses following local nomograms. Row 2. Medication: Alteplase. Uses: Treatment of acute ischemic stroke, P E, S T E M I, frostbite, peripheral arterial occlusions, prosthetic heart valvular thrombus, retinal artery and vein occlusions; also used to restore intravascular catheter function when clotted. Mechanism of Action: Initiates local fibrinolysis, clot lysis, by binding to clot fibrin, converting plasminogen to plasmin. Route of Administration: I V. Side Effects: Potentially life-threatening bleeding, hypotension, reperfusion arrhythmias in coronary thrombolysis. Special Considerations: Monitor vital signs and E C G during administration. Perform invasive procedures cautiously due to increased risk of bleeding. Carefully monitor I V sites and hemoglobin to assess for bleeding. Follow local protocols and guideline-driven monitoring protocols. Row 3. Medication: Tenecteplase. Uses: Lysis of intracoronary thrombi in S T E M I, acute ischemic stroke. Mechanism of Action: Tenecteplase is essentially alteplase with three mutations, making it more fibrin specific and providing a longer duration of action. Route of Administration: I V. Side Effects: Potentially life-threatening bleeding, hypotension, fever, reperfusion arrhythmias in coronary thrombolysis. Special Considerations: Perform invasive procedures cautiously due to increased risk of bleeding. Carefully monitor I V sites and hemoglobin to assess for bleeding. The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 4.

Medication: Abciximab. Uses: Prevention of platelet aggregation in patients undergoing or awaiting P C I. Mechanism of Action: Impairs platelet aggregation by binding to platelet receptors. Route of Administration: I V. Side Effects: Potentially life-threatening bleeding, hypotension, chest pain, back pain, antibody development, especially with repeat dosing. Special Considerations: Intended for coadministration with aspirin and heparin infusion to maintain a therapeutic bleeding time measured by A C T. May be administered directly through the catheter during P C I. Monitor coagulation parameters, hemoglobin and platelets, and signs and symptoms of bleeding, especially the sheath insertion site. Row 5. Medication: Eptifibatide. Uses: Treatment of patients with A C S, including those undergoing P C I and those managed medically. Mechanism of Action: Blocks platelet receptors, inhibiting platelet aggregation and preventing thrombosis. Route of Administration: I V. Side Effects: Potentially life-threatening bleeding, hypotension, local site reactions. Special Considerations: Monitor coagulation parameters, hemoglobin and platelets, and signs and symptoms of bleeding, especially the sheath insertion site. Row 6. Medication: Tirofiban. Uses: Adjunct treatment of N S T E M I and U A patients; prevention of platelet aggregation in patients undergoing or awaiting P C I. Mechanism of Action: Impairs platelet aggregation in a dose- and concentration-dependent manner. Route of Administration: I V. Side Effects: Potentially life-threatening bleeding. Special Considerations: Monitor coagulation parameters, hemoglobin and platelets, signs and symptoms of bleeding, especially the sheath insertion site. Text below the table reads, Abbreviations: A C S, acute coronary syndrome; A C T, activated clotting time; a P T T, activated partial thromboplastin time; D V T, deep venous thrombosis; E C G, electrocardiogram; I V, intravenous; N S T E M I, non–S T-segment elevation myocardial infarction; P C I, percutaneous coronary intervention; P E, pulmonary embolism; S T E M I, S T-segment elevation myocardial infarction; U A, unstable angina.

Back to Table

The table shows six columns: Medication, Uses, Mechanism of Action, Route of Administration, Side Effects, and Special Considerations. Row entries are as follows. Row 1. Medication: Insulin, regular. Uses: Treatment of diabetic ketoacidosis, hyperglycemia during critical illness, hyperkalemia. Mechanism of Action: Regulates metabolism of carbohydrates, protein, and fats; promotes intracellular movement of potassium. Route of Administration: Subcutaneous, I V. Side Effects: Hypoglycemia, hypokalemia, hypertrophy at subcutaneous injection sites. Special Considerations: For critically ill patients on insulin infusions, monitor blood glucose at a minimum hourly during transport. Arterial or venous whole-blood sampling is recommended for patients in shock, with significant edema, or on vasopressors. Row 2. Medication: Furosemide. Uses: Management of edema associated with heart failure, hepatic or renal disease, acute pulmonary edema, treatment of hypertension. Mechanism of Action: Inhibits reabsorption of sodium and chloride in the ascending loop of Henle and distal renal tubules. Route of Administration: Oral, I M, I V, I O. Side Effects: Hypovolemia, electrolyte abnormalities, dizziness, hearing impairment, potentially permanent with rapid I V administration of high doses. Special Considerations: Monitor blood pressure, serum electrolytes, particularly potassium, renal function, and fluid volume status. Row 3. Medication: Bumetanide. Uses: Management of edema secondary to heart failure, hepatic disease, or renal disease. Mechanism of Action: Inhibits reabsorption of sodium and chloride in the ascending loop of Henle and proximal renal tubules; does not act on distal tubules. Route of Administration: Oral, I M, I V, I O. Side Effects: Hypovolemia, electrolyte abnormalities, dizziness. Special Considerations: Monitor blood pressure, serum electrolytes, particularly potassium, renal function, and fluid volume status. Text below the table reads, Abbreviations: I M, intramuscular; I O, intraosseous; I V, intravenous.

Back to Table

The table shows five columns: Name, Abbreviation, Normal, Critically Low, and Critically High. Under head Electrolytes and Other Chemicals, row entries are as follows. Row 1. Sodium in milliequivalents per liter. N a plus. 134 to 142. Less than 125. Greater than 145. Row 2. Potassium in milliequivalents per liter. K plus. 3.7 to 5.1. Less than 3.0.

Greater than 5.0. Row 3. Chloride in milliequivalents per liter. C l negative. 98 to 108. Varies. Varies. Row 4. Calcium, total in milligrams per deciliter. C a plus 2. 8.6 to 10.3. Less than 6.5. Greater than 13.5. Row 5. Calcium, ionized in millimoles per liter. C a plus 2 I. 1.15 to 1.27. Varies. Varies. Row 6. Total carbon dioxide in milliequivalents per liter. C O 2. 22 to 30. Less than 15. Greater than 40. Row 7. Phosphate in milliequivalents per liter. P O 4. 2.3 to 4.1. Less than 1.2. Greater than 9. Under head Metabolites, row entries are as follows. Row 8. Blood urea nitrogen in milligrams per deciliter. B U N. 6 to 25. Less than 2. Greater than 80. Row 9. Creatinine in milligrams per deciliter. C r. 0.4 to 1.3. Less than 0.4. Greater than 2.8. Row 10. Lactate or lactic acid in millimoles per liter. Not Available. Venous: 0.4 to 2.0; Arterial: 0.5 to 1.6. Varies. Greater than 4.99. Under head Proteins, row entries are as follows. Row 11. Protein, total in grams per deciliter. Not Available. 6.5 to 8.3. Varies. Varies. Row 12. Albumin in grams per deciliter. Not Available. 3.9 to 5.0. Varies. Varies. Row 13. Myoglobin in milligrams per deciliter. Not Available. 19 to 92. Varies. Varies. Row 14. Troponin I in nanograms milliliter. c T n I. 0 to 0.4, negative. Varies. Varies. Under head Enzymes, row entries are as follows. Row 15. Lactate dehydrogenase in units per liter. L D H. 120 to 300. Varies. Varies. Row 16. Alanine aminotransferase in units per liter. A L T. 5 to 40. Not Available. Varies. Row 17. Aspartate aminotransferase in units per liter. A S T. 5 to 40. Not Available. Varies. Row 18. Alkaline phosphatase in units per liter. A L P. 35 to 110. Varies. Varies. Row 19. Amylase in units per liter. Not Available. 27 to 131. Varies. Varies. Row 20. Lipase in units per liter. Not Available. 31 to 186. Varies. Varies. Row 21. Creatine kinase in units per liter. C K. 40 to 150. Varies. Varies. The table shows five columns: Name, Abbreviation, Normal, Critically Low, and Critically High. Under head Coagulation, row entries are as follows. Row 22. Prothrombin times. P T. 10 to 13. Not Available. Varies. Row 23. Activated partial thromboplastin times. a P T T. 25 to 40. Not Available. Greater than 60. Row 24. International normalized ratio. I N R. 2.0 to 3.0, target for therapeutic anticoagulation therapy; Normal range for a patient who is not anticoagulated: 0.8 to 1.2. Varies. Varies. Under head Serum, row entries are as follows. Row 25. Osmolality in milliosmoles per kilogram. Not Available. 275 to 295. Less than 240. Greater than 320. Under head Complete Blood Count, C B C, row entries are as follows. Row 26. Hematocrit in percent. H c t. 41 to 50. Less than 20. Greater than 60. Row 27. Hemoglobin in grams per deciliter. H g b. 12.0 to 17.4. Less than 7. Greater than 20. Row 28. Erythrocytes, times 10 to the power of 6 per milliliter. R B C. 4.0 to 5.5. Varies. Varies. Row 29. Leukocytes per milliliter. W B C. 4,500 to 11,000. Less than 2,000. Greater than 30,000. Under head Arterial Blood Gases, row entries are as follows. Row 30. Percentage of hydrogen ions. p H. 7.35 to 7.45. Less than 7.2. Greater than 7.6. Row 31. Partial pressure of oxygen in millimeters of mercury. P a o 2. 80 to 100. Less than 40. Not Available. Row 32. Partial pressure of carbon dioxide in millimeters of mercury. P a c o 2. 35 to

45. Less than 20. Greater than 77. Row 33. Bicarbonate in milliequivalents per liter. H C O 3 negative. 21 to 28. Less than 10. Greater than 40. Row 34. Base excess in milliequivalents per liter. B E. Negative 2 to plus 3. Less than negative 5. Greater than plus 5. Text for superscript a reads, It is important to know the normal range for the laboratory where the specimen is tested. Source line reads, Data from Fischbach F T, Fischbach M A, Stout K, editors. Manual of Laboratory and Diagnostic Tests. Tenth edition. Philadelphia, P A: Lippincott Williams and Wilkins; 2017.

Back to Table

The table shows three columns: Left Ventricular Heart Failure, Right Ventricular Heart Failure, and Biventricular Heart Failure. Row entries are as follows. Row 1. Heart rate: Increased. Increased. Increased or decreased. Row 2. Blood pressure: W N L in the initial stage, then decreases as patient decompensates. W N L in the initial stage, then decreases as patient decompensates. Decreased. Row 3. Pulse pressure: Narrow. Narrow. Narrow. Row 4. Central venous pressure or right atrial pressure: W N L. Increased. Increased. Row 5. Pulmonary capillary wedge pressure: Increased. Decreased. Increased. Row 6. Cardiac output or cardiac index: Decreased. Decreased. Decreased. Row 7. Systemic vascular resistance: Increased. Increased. Increased. Row 8. S v o 2: Decreased. Decreased. Decreased. Row 9. Urinary output: Decreased. Decreased. Decreased. Row 10. Jugular vein distention: Absent.

Present. Present. Row 11. Heart sounds: S 3. Normal. S 3 or S 4. Row 12. Edema: Pulmonary. Peripheral. Systemic. Text below the table reads, Abbreviations: S v o 2, venous oxygen saturation; W N L, within normal limits.

Back to Table

The table shows four columns: Class 1, Class 2, Class 3, and Class 4. Row entries are as follows. Row 1. Blood loss in milliliters: Less than 750. 750 to 1,500. 1,500 to 2,000. Greater than 2,000. Row 2. Blood loss in percent: Less than 15. 15 to 30. 30 to 40. Greater than 40. Row 3. Heart rate in beats per minute: Less than 100. Greater than 100. Greater than 120. Greater than 140. Row 4. Blood pressure: Within normal limits. Normal. Low. Low. Row 5. Pulse pressure: Within normal limits. Narrow. Narrow. Very narrow. Row 6. Capillary refill: Within normal limits. Delayed. Delayed. Absent. Row 7. Respiratory rate in breaths per minute: 14 to 20. 20 to 30. 30 to 40. Greater than 35. Row 8. Central nervous system or mental status: Slightly anxious. Mildly anxious. Anxious and confused. Confused and lethargic. Row 9. Skin condition: Cool, normal color. Cool, pale. Cold, pale, moist. Cold, cyanotic. Row 10. Urine output in milliliters per hour: Greater than 30. 20 to 30. 5 to 15. Minimal or none. Row 11. Fluid replacement: Crystalloids. Crystalloids. Crystalloids and blood. Crystalloids and blood. Source line reads, Modified from American College of Surgeons Committee on Trauma. Advanced Trauma Life Support for

Doctors: A T L S Student Course Manual. Ninth edition. Chicago, I L: American College of Surgeons; 2012.

Back to Table

The table shows two main columns: Hemodynamic Findings in Distributive Shock and Comparison With Hypovolemic Shock. Column 1 is further subdivided into two columns: Neurogenic Shock and Anaphylactic Shock. Row entries are as follows. Row 1. Heart rate: Decreased. Increased. Increased. Row 2. Blood pressure: Decreased. Decreased. Within normal limits in the initial stage, then decreases as the patient decompensates. Row 3. Pulse pressure: Normal. Narrow. Narrow. Row 4. Central venous pressure or renal artery pressure: Decreased. Decreased. Decreased. Row 5. Pulmonary capillary wedge pressure: Decreased. Decreased. Decreased. Row 6. Cardiac output or cardiac index: Decreased. Decreased. Decreased. Row 7. Systemic vascular resistance, S V R, or S V R index, S V R I: Decreased. Decreased. Increased. Row 8. S v o 2: Decreased. Decreased. Decreased. Row 9. Urinary output: Decreased. Decreased. Decreased. Row 10. Skin: Normal color, warm, dry. Flushed, warm to hot, pruritus, hives. Cool, pale, moist. Text below the table reads, Abbreviation: S v o 2, venous oxygen saturation.

Back to Table

The table shows two main columns: System and Score. Column 2 is further subdivided into five columns: 0, 1, 2, 3, and 4. Row entries are as follows. Row 1. Respiration; P a o 2 or F i o 2 in millimeters of mercury, Kilo Pascal. Greater than or equal to 400; 53.3. Less than or equal to 400; 53.3. Less than 300; 40. Greater than 200; 26.7, with respiratory support. Less than 100; 13.3, with respiratory support. Row 2. Coagulation; Platelets, times 10 powered 3 per microliter. Greater than or equal to 150. Less than 150. Less than 100. Less than 50. Less than 20. Row 3. Liver; Bilirubin, milligrams per deciliter, micromoles per liter. Less than 1.2; 20. 1.2 to 1.9; 20 to 32. 2.0 to 5.9; 33 to 101. 6.0 to 11.9; 102 to 204. Greater than 12.0; 204. Row 4. Cardiovascular. M A P greater than or equal to 70 millimeters of mercury. M A P less than 70 millimeters of mercury. Dopamine less than 5 or dobutamine, any dose. Dopamine 5.1 to 15 or epinephrine less than or equal to 0.1 or norepinephrine less than or equal to 0.1, superscript b. Dopamine greater than 15 or epinephrine greater than 0.1 or norepinephrine greater than 0.1, superscript b. Row 5. Central nervous system; Glasgow Coma Scale score, superscript c. 15. 13 to 14. 10 to 12. 6 to 9. Less than 6. Row 6. Renal; Creatinine, milligrams per deciliter, micromoles per liter; Urine output, milliliters per day. Less than 1.2; 110. 1.2 to 1.9; 110 to 170. 2.0 to 3.4; 171 to 299. 3.5 to 4.9, 300 to 440; less than 500. Greater than 5.0, 440; less than 200. Text below the table reads, Abbreviations: F i o 2, fraction of inspired oxygen; M A P, mean arterial pressure; P a o 2, partial pressure of oxygen.

Text for superscript a reads, Adapted from Vincent J L, Moreno R, Takala J, et al; Working Group on Sepsis-Related Problems of the European Society of Intensive Care Medicine. The S O F A, Sepsis-related Organ Failure Assessment, score to describe organ dysfunction or failure. Intensive Care Medicine. 1996; 22, 7: 707 to 710. Text for superscript b reads, Catecholamine doses are given as microgram per kilogram per minute for at least 1 hour. Text for superscript c reads, Glasgow Coma Scale scores range from 3 to 15; higher scores indicate better neurologic function. Source line reads, Reproduced from Vincent J L, Moreno R, Takala J, et al; Working Group on Sepsis-Related Problems of the European Society of Intensive Care Medicine. Back to Table

Text is listed under three heads. Under head Eye Opening, the following are listed. Spontaneous, Score 4. In response to sound, Score 3. In response to pressure, Score 2. No response, Score 1. Under head Best Verbal Response, the following are listed. Oriented conversation, Score 5. Confused conversation, Score 4. Words, Score 3. Sounds, Score 2. None, Score 1. Under head Best Motor Response, the following are listed. Obeys commands, Score 6.

Localizes to pressure, Score 5. Withdraws from pressure, Score 4. Abnormal flexion, Score 3. Extension, Score 2. No response, Score 1. Text for superscript a reads, Some systems use a, Not testable, N T, score for any element that cannot be tested. Eye opening cannot be tested in a patient whose eyes are closed due to a local factor, such as swelling; verbal response cannot be tested in a patient who has a preexisting factor interfering with communication, such as mutism; and motor response cannot be tested in a patient who has preexisting paralysis or other limiting factor. Text below the table reads, Score: 13 to 15 may indicate mild dysfunction, although 15 is the score a person without neurologic impairment would receive. Score: 9 to 12 may indicate moderate dysfunction. Score: 8 or less is indicative of severe dysfunction.

Back to Table

The table shows four columns: I S S Region, Injury, A I S, and Square of the Top Three A I S Scores. Row entries are as follows. Row 1. Head and neck, No injury, 0, No data. Row 2. Face, Unstable facial fracture, 4, 16. Row 3. Chest, Flail chest, 5, 25. Row 4. Abdomen, Liver laceration, 4, 16. Row 5. Extremity, No injury, 0, No data. Row 6. External, Abrasion to right upper quadrant of abdomen, 3, No data. Row 7. Totals, No data, 16, 57. Back to Table

The table shows three columns: Category, Sample Questions, and Order of Loss. Row entries are as follows. Row 1. Category: Time. Sample Questions: What day is it? What is the date? What is the month, the year? What is the season? What is the time of day? Row 2. Category: Place. Sample Questions: What is the name of the place we are in? Which type of vehicle are we in? What is the name of the town or city? Row 3. Category: Person. Sample Questions: What is your name? What is your job? Where do you live? Order of Loss decreases from top to bottom.

Back to Table

The table shows four columns: Cranial Nerve Number, Cranial Nerve Name, Function, and Test. Row entries are as follows. Row 1. Cranial Nerve Number: 1. Cranial Nerve Name: Olfactory. Function: Sense of smell. Test: Patient smells aromatic substance, coffee or soap but not ammonia or other irritants. Row 2. Cranial Nerve Number: 2. Cranial Nerve Name: Optic. Function: Vision. Test: Visual acuity test, the Snellen chart; Optic disk, fundoscopy; Fields, confrontation. Row 3. Cranial Nerve Number: 3. Cranial Nerve Name: Oculomotor. Function: Medial and upward and downward movement of the eye; Constriction of the pupil;

Elevation of eyelids; Consensual light response; Accommodation and convergence. Test: Extraocular movements, pupillary size and equality, and symmetry of response to a light shined in the eyes. Row 4. Cranial Nerve Number: 4. Cranial Nerve Name: Trochlear. Function: Moves eyes upward and downward. Test: Tested with cranial nerves 3 and 6. Row 5. Cranial Nerve Number: 5. Cranial Nerve Name: Trigeminal. Function: Sensation for face, scalp, cornea, and nasal and oral cavities; Movement of jaw. Test: Prick the patient's face with a pin and touch the face lightly with a piece of cotton; Patient clenches their teeth together. Row 6. Cranial Nerve Number: 6. Cranial Nerve Name: Abducens. Function: Moves eyes laterally. Test: Tested with cranial nerves 3 and 4. Row 7. Cranial Nerve Number: 7. Cranial Nerve Name: Facial. Function: Controls facial expression and taste for interior two-thirds of tongue. Test: Direct the patient to smile, whistle, bare the teeth, and pucker lips; Also, the patient should close their eyes and wrinkle the forehead. Row 8. Cranial Nerve Number: 8. Cranial Nerve Name: Acoustic. Function: Hearing and equilibrium. Test: Caloric test in unconscious patients; Doll's eyes test. Row 9. Cranial Nerve Number: 9. Cranial Nerve Name: Glossopharyngeal. Function: Voluntary muscles for swallowing and phonation; Secretory and salivary glands; Carotid reflex. Test: Test for palatal elevation, swallowing and gag reflexes, superscript a and glottal and palatal sounds. Row 10. Cranial Nerve Number: 10. Cranial Nerve Name: Vagus. Function: Voluntary muscles for phonation and swallowing; Involuntary activity of visceral muscles of the heart, lungs, and digestive tract; Carotid reflex. Test: Test for palatal elevation, swallowing and gag reflexes, superscript a and glottal and palatal sounds. Row 11. Cranial Nerve Number: 11. Cranial Nerve Name: Spinal accessory. Function: Shrugging of shoulders and turning of head. Test: Ability to shrug shoulders and turn head against resistance. Row 12. Cranial Nerve Number: 13. Cranial Nerve Name: Hypoglossal. Function: Movement of tongue and taste for posterior third of the tongue. Test: Ability to protrude tongue and push tongue against cheek. Text for superscript a reads, Ten percent of the normal population lacks a gag reflex.

Back to Table

The table shows four columns: Structure, Normal, Abnormal, and Interpretation of Abnormal Findings. Row entries are as follows. Row 1 A. Structure: Optic disk. Normal: Round or slightly oval in shape; Yellow-red color; Clearly defined margins. Abnormal: Papilledema: swelling of the disk, including disappearance of the optic cup. Interpretation of Abnormal Findings: Increased intracranial pressure, usually within 24 to 48 hours. Row 1 B. Structure: Optic disk. Normal: No data. Abnormal: Papillitis: inflammation of the optic nerve. Interpretation of Abnormal Findings: Multiple sclerosis, idiopathic. Row 1 C. Structure: Optic disk. Normal: No data. Abnormal: Optic atrophy: decreased visual acuity and a change in color of the optic disk to light pink, white, or gray. Interpretation of Abnormal Findings: Primary: optic nerve compression, optic nerve ischemia. Secondary: following papilledema. Row 2. Structure: Optic cup. Normal: Slightly on the nasal side of the center of the optic disk. Diameter is normally less than 50 percent of the disk. Abnormal: Cup may appear deep. Interpretation of Abnormal Findings: Chronic, or idiopathic, glaucoma. Row 3 A. Structure: Blood vessels. Normal: Arteries are lightly colored and are two-thirds the diameter of veins. Abnormal: Arterial narrowing and vessel irregularity. Interpretation of Abnormal Findings: Hypertensive retinopathy. Row 3 B. Structure: Blood vessels. Normal: Veins are burgundy colored and may pulsate near the disk. Abnormal: Tortuous vessels. Interpretation of Abnormal Findings: Hypertensive retinopathy. Row 4 A. Structure: Retinal background. Normal: Pigmented background: normal in people with dark skin; if striped, it is called tigroid. Pale: clear is normal in people with fair skin. Abnormal: Red lesions, Dot hemorrhages: microaneurysms seen adjacent to blood vessels. Interpretation of Abnormal Findings: Diabetic retinopathy. Row 4 B. Structure: Retinal background. Normal: No data. Abnormal: Blot hemorrhages: bleeds in the deep retinal layer from microaneurysms. Interpretation of Abnormal Findings: Hypertensive retinopathy. Row 4 C. Structure: Retinal background. Normal: No data. Abnormal: Flame hemorrhages: superficial bleed, shaped by nerve fibers into a fan that points toward the disk. Interpretation of Abnormal Findings: Subarachnoid hemorrhage. Row 4 D. Structure: Retinal background. Normal: No data. Abnormal: Subhyaloid hemorrhages: irregular superficial hemorrhages usually with a flat top. Interpretation of Abnormal Findings: Diabetes and hypertension. Row 4 E. Structure: Retinal background. Normal: No data. Abnormal: White and yellow lesions, Hard exudates: yellow, sharply edged lesions that may form a ring around the macula. Interpretation of Abnormal Findings: Diabetes, systemic lupus erythematosus, acquired immunodeficiency syndrome. Row 4 F. Structure: Retinal background. Normal: No data. Abnormal: Cotton wool spots: white fluffy spots caused by retinal infarcts. Interpretation of Abnormal Findings: Hypertension.

Back to Table

The table shows four columns: Criteria, Yes, Unknown, and No. Row entries are as follows. Row 1. 1. Age greater than 45 years. Yes checkbox. Unknown checkbox. No checkbox. Row 2. 2. History of seizures or epilepsy absent. Yes checkbox. Unknown checkbox. No checkbox. Row 3. 3. Symptoms less than 24 hours. Yes checkbox. Unknown checkbox. No checkbox. Row 4. 4. At baseline, patient is not wheelchair bound or bedridden. Yes checkbox. Unknown checkbox. No checkbox. Row 5. 5. Blood glucose between 60 and 400 milligrams per deciliter. Yes checkbox. Unknown checkbox. No checkbox. Row 6. 6. Obvious asymmetry, right versus left, in any of the following three exam categories, must be unilateral: 1. Facial smile and grimace. Equal: Checkbox. Right Weak: Droop checkbox. Left Weak: Droop checkbox. 2. Grip. Equal: Checkbox. Right Weak: Weak grip and No grip checkboxes. Left Weak: Weak grip and No grip checkboxes. 3. Arm strength. Equal: Checkbox. Right Weak: Drifts down and Falls rapidly checkboxes. Left Weak: Drifts down and Falls rapidly checkboxes. Text for superscript a reads, Interpretation: If criteria 1 through 6 are marked yes, the probability of a stroke is 97 percent.

Back to Table

The table shows four columns: Depth; Color and Vascularity; Surface Appearance and Pain; and Swelling, Healing, and Scarring. Row entries are as follows. Row 1. Superficial, first degree. Erythematous, pink and red. No blisters; Dry and tender. Slight edema; Heals easily without scarring. Row 2. Superficial to partial thickness, second degree. Erythematous, bright pink or red, mottled; Blanches with brisk capillary refill. Intact blisters, moist when removed; Weeping wounds and extremely painful. Moderate edema; Easily heals but with skin discoloration. Row 3. Deep to partial thickness, second degree. Red, waxy-white; Blanches with slow capillary refill. Broken blisters, wet; Sensitive to pressure, but not to light touch. Marked edema; Heals slowly with hypertrophic scars. Row 4. Full thickness, third degree. White, black to red or tan; No blanching, vessels thrombosed; Poor distal circulation. Dry, leathery; Hairs pull out easily; Anesthetic. Skin grafting required; Scarring likely after healing. Row 5. Subdermal, fourth degree. Charred. Obvious subcutaneous tissue involvement; Anesthetic. Skin grafting and, or flap required; Scarring after healing.

Back to Table

Text is listed under five heads. Under head 1 Chamber Paced, the following are listed. V: Ventricle. A: Atrium. D: Dual, A plus V. O: None. S: Single, A or V. Under head 2 Chamber Sensed, the following are listed. V: Ventricle. A: Atrium. D: Dual, A plus V. O: None. S: Single, A or V. Under 3 Response to Sensing, the following are listed. T: Triggered. I: Inhibited. D: Dual, superscript b. O: None. Under head 4 Programmable Functions; Rate Modulation, superscript a, the following are listed. P: Simple programmable, superscript c. M: Multiprogrammable, superscript d. C: Communicating, superscript e. R: Rate modulating. O: None. Under head 5 Antitachyarrhythmia Functions, the following are listed. P: Pace. S: Shock. D: Dual, superscript f. O: None. Text for superscript a reads, This sequence is hierarchical; it is assumed that if a pacemaker has rate modulation capabilities, R, it can also communicate, C. Text for superscript b reads, Inhibited and triggered. In single-chamber mode, triggered means initiating a pacing pulse immediately after sensing an intrinsic event. In dual-chamber mode, this term means that a sensed atrial event will initiate an atrioventricular, A V, delay. Text for superscript c reads, Rate and forward slash or output. Text for superscript d reads, Rate, output, sensitivity, and so forth. Text for superscript e reads, Can send information to and receive information from the programmer. Text for superscript f reads, Pace and shock available.

Back to Table

The table shows two main columns: Measurement and Shock Type. Column 2 is further subdivided into three columns: Hypovolemic, Cardiogenic, and Distributive. Row entries are as follows. Row 1. Preload, S V V, P P V, P V I, C V P, P C W P. Decreased. Increased. Decreased. Row 2. Afterload, S V R, P V R. Increased. Increased. Decreased. Row 3. Cardiac output. Decreased. Decreased. Increased. Row 4. S v o 2 or S c v o 2. Decreased. Decreased. Increased. Row 5. Blood pressure, M A P. Decreased. Increased. Decreased. Text below the table reads, Abbreviations: C V P, central venous pressure; M A P, mean arterial pressure; P C W P, pulmonary capillary wedge pressure; P P V, pulse pressure variation; P V R, pulmonary vascular resistance; P V I, pleth variability index; S c v o 2, mixed central venous oxygen saturation; S v o 2, mixed venous oxygen saturation; S V R, systemic vascular resistance; S V V, stroke volume variation.

Back to Table

The table shows four columns: Error, Definition, Waveform Characteristics, and Physiologic Effects. Row entries are as follows. Row 1. Early inflation. Inflation of the I A B before aortic valve closure. I A B inflation before the dicrotic notch; diastolic augmentation encroaches onto systole, may be unable to distinguish the two. Possible premature aortic valve closure; possible increase in L V, E D V, E D P, or P C W P; increased L V wall stress, afterload; aortic regurgitation;

increased M V o 2. Row 2. Late inflation. I A B inflation occurs markedly later than aortic valve closure. I A B inflation after the dicrotic notch; absence of sharp V. Suboptimal coronary artery perfusion. Row 3. Early deflation. Premature I A B deflation, during the diastolic phase. Sharp drop following diastolic augmentation; suboptimal diastolic augmentation; assisted aortic E D P may be equal to or less than unassisted aortic E D P; assisted systolic pressure may rise. Suboptimal coronary artery perfusion; potential for retrograde coronary and carotid blood flow; suboptimal afterload reduction; increased M V o 2. Row 4. Late deflation. Balloon deflation late in the cardiac cycle. Assisted aortic E D P may be equal to unassisted aortic E D P; prolonged rate of rise of assisted systole; diastolic augmentation may appear widened. Afterload reduction essentially absent; increased M V o 2 because of prolonged isovolumetric contraction and greater resistance to L V ejection; increased afterload if I A B impinges on L V ejection. Text below the table reads, Abbreviations: E D P, end-diastolic pressure; E D V, end-diastolic volume; I A B, intra-aortic balloon; L V, left ventricular; M V o 2, myocardial oxygen consumption; P C W P, pulmonary capillary wedge pressure.

Back to Table

The table shows four columns: Laboratory Study, Normal Range, Causes of Low Levels, and Causes of High Levels. Row entries are as follows. Row 1. Thyroid-stimulating hormone, T S H. 0.4 to 4.2 milli-international units per liter. Hyperthyroidism, or pituitary gland failure. Thyroid gland failure, or pituitary gland tumor. Row 2. T 3, triiodothyronine. 60 to 180 nanograms per deciliter. Hypothyroidism. Hyperthyroidism. Row 3. Total T 4, thyroxine. 5.5 to 12.5 micrograms per deciliter. Hypothyroidism. Hyperthyroidism. Row 4. Free T 4, thyroxine; 0.9 to 2.3 nanograms per deciliter. Hypothyroidism. Hyperthyroidism. Row 5. R T 3 U, triiodothyronine reuptake. 24 percent to 37 percent. Hypothyroidism. Hyperthyroidism. Row 6. Triglycerides. Less than 160 milligrams per deciliter. Clinically irrelevant with respect to thyroid disorders. Possible hypothyroidism. Row 7. Radioactive iodine uptake. 8 percent to 25 percent. Hypothyroidism. Hyperthyroidism. Row 8. Glucose tolerance test. Fasting: 70 to 1,100 milligrams per deciliter. Clinically irrelevant with respect to thyroid disorders. Hyperthyroidism. Row 9. Thyroglobulin antibody. Less than 2 nanograms per milliliter. Clinically irrelevant with respect to thyroid disorders. Hyperthyroidism.

Back to Table

The table shows five columns: Organism; General Information; Cell Wall and Cell Membrane Components; Drug Classes, Groups of Actions, Use; and Medications. Row entries are as follows. Row 1. Organism: Bacteria. General Information: Prokaryote versus eukaryote bacteria: prokaryotes. Cellularity: unicellular. Reproduction: binary fission. Cell Wall and Cell Membrane Components:

Peptidoglycan cell wall. No sterols in the membrane, except Mycoplasma. Mycolic acid in the cell wall of mycobacteria. Drug Classes, Groups of Actions, Use: Cell wall synthesis inhibitors, Beta-lactams, Medications: Penicillins and cephalosporins; Use: Glycopeptides, Medications: Vancomycin; Use: Protein synthesis inhibitors, Tetracyclines, Medications: Doxycycline; Use: Aminoglycosides, Medication: Amikacin and gentamicin; Use: Macrolides, Medication: Erythromycin, many brand names; Use: D N A and R N A synthesis inhibitors, Quinolones or fluoroquinolones, Medication: Ciprofloxacin, Polymyxin B; Use: Alter cell membrane permeability Antimetabolites, Sulfonamides, Medication: Sulfamethoxazole. Row 2. Organism: Viruses. General Information: Prokaryote versus eukaryote: neither. Cellularity: acellular. Reproduction: Not available. Cell Wall and Cell Membrane Components: None, lack cells. Drug Classes, Groups of Actions, Use: Viral attachment inhibitor, Medications: Enfuvirtide; Use: Viral uncoating inhibitor, influenza, Medications: Amantadine, Symmetrel, and rimantadine; Use: Neuraminidase inhibitors, influenza, Medications: Zanamivir and oseltamivir; Use: D N A and R N A synthesis inhibitors; H I V, herpes, cytomegalovirus, Medication: Acyclovir, ganciclovir and zidovudine; Use: Protease inhibitors, H I V, Medication: Indinavir and saquinavir; Use: Interferon, hepatitis. Medication: Interferon. Row 3. Organism: Protozoa. General Information: Prokaryote versus eukaryote: eukaryotes. Cellularity: unicellular. Reproduction: asexual or sexual. Cell

Wall and Cell Membrane Components: No cell wall. Drug Classes, Groups of Actions, Use: Antimetabolites, Medications: Trimethoprimsulfamethoxazole combination; Use: D N A synthesis inhibitors, Nitroimidazoles, unknown mode of action, Medication: Metronidazole; Use: Quinolines, Medication: Chloroquine and quinacrine. Row 4. Organism: Helminths. General Information: Prokaryote versus eukaryote: eukaryotes. Cellularity: multicellular. Reproduction: complex. Cell Wall and Cell Membrane Components: No cell wall. Drug Classes, Groups of Actions, Use: Antimetabolites, Benzimidazole. Medications: Mebendazole and praziquantel. The table shows five columns: Organism; General Information; Cell Wall and Cell Membrane Components; Drug Classes, Groups of Actions, Use; and Medications. Row entries are as follows. Row 5. Organism: Fungi. General Information: Prokaryote versus eukaryote: eukaryotes. Cellularity: unicellular, yeasts, or multicellular, molds. Reproduction: asexual or sexual. Cell Wall and Cell Membrane Components: Chitin cell wall, Unique sterols, ergosterol, in the membrane. Drug Classes, Groups of Actions, Use: Ergosterol synthesis inhibitors, Azoles. Medications: Ketoconazole, Nizoral and miconazole, Monistat, Micatin; Use: Allylamines, Medication: Terbinafine, Lamisil; Use: Alters cell membrane permeability, Polyene, Medication: Amphotericin B; Use: Mitotic inhibitor, prevents cell replication, Medication: Griseofulvin. Row 6. Organism: Prions. General Information: Prokaryote versus eukaryote: neither. Cellularity: acellular. Reproduction: Not applicable.

Cell Wall and Cell Membrane Components: None, lack cells. Drug Classes, Groups of Actions, Use: Not applicable. Medications: Not applicable. Text below the table reads, Abbreviations: D N A, deoxyribonucleic acid; H I V, human immunodeficiency virus; N slash A, not applicable; R N A, ribonucleic acid.

Back to Table

The table shows four columns: Year; Colloquial Name, Subtype; Source; and Impact. Under Pandemics, row entries are as follows. Row 1. 1918. Spanish flu, H 1 N 1 viruses such as swine flu. Possible emergence from swine or an avian host of a mutated H 1 N 1 virus. Pandemic with more than 50 million deaths globally. Row 2. 1957. Asian flu, H 2 N 2. Possible mixed infection of an animal with human H 1 N 1 and avian H 2 N 2 virus strains in Asia. Pandemic; H 1 N 1 virus disappeared. Row 3. 1968. Hong Kong flu, H 3 N 2. High probability of mixed infection of an animal with human H 2 N 2 and avian H 3 N x virus strains in Asia. Pandemic; H 2 N 2 virus disappeared. Row 4. 1977. Russian flu, H 1 N 1. Source unknown but virus is almost identical to human epidemic strains from 1950; reappearance detected at almost the same time in China and Siberia. Benign pandemic, primarily involving people born after the 1950s; H 1 N 1 virus has cocirculated with H 3 N 2 virus in humans since 1977. Under Incidents With Limited Spread, row entries are as follows. Row 5. 1976. Swine flu, H 1 N 1. United States and New Jersey; virus enzootic in U S swine herds since at least 1930. Localized outbreak in military training camp, with one death. Row 6. 1986. H 1 N 1. The Netherlands; swine virus derived from avian source. One adult with severe pneumonia. Row 7. 1988. Swine flu, H 1 N 1. United States and Wisconsin; swine virus. Pregnant woman died after exposure to a sick pig. Row 8. 1993. H 3 N 2. The Netherlands; swine reassortant between old human H 3 N 2, 1973 and 1975-like, and avian H 1 N 1. Two children with mild disease; fathers suspected of transmitting the virus to the children after being infected by pigs. Row 9. 1995. H 7 N 7. United Kingdom; duck virus. One adult with conjunctivitis. Row 10. 1997. Avian flu, H 5 N 1. Hong Kong; poultry virus. Outbreak in 2003 resulted in 774 deaths worldwide. Row 11. 2009. Novel H 1 N 1. Mexico. From April 12, 2009, to April 10, 2010, approximately 60.8 million cases, 274,304 hospitalizations, and 12,469 deaths. Source line reads, Modified from H 1 N 1 flu. The table shows five columns: Stage of Labor; Average Time, Nullipara; Average Time, Multipara; Frequency of Contractions; and Characteristics. Row entries are as follows. Row 1. Stage of Labor: Prodromal stage. Average Time, Nullipara: Varies. Average Time, Multipara: Varies. Frequency of Contractions: Not available. Characteristics: Bloody show, mucus mixed with blood, expelled from the vagina. Row 2. Stage of Labor: First stage. Average Time, Nullipara: 8 to 12 hours. Average Time, Multipara: 6 to 8 hours. Frequency of Contractions: 5- to 15-minutes intervals. Characteristics: Labor pains and contraction of the uterus begin. Pain may radiate into the small of the back. Amniotic sac often ruptures toward the end of this stage, signified by a gush of fluid from the vagina. This stage lasts until the cervix is fully dilated. Row 3. Stage of Labor: Second stage. Average Time, Nullipara: 1 to 2 hours. Average Time, Multipara: 30 minutes. Frequency of Contractions: 2 to 3 minutes apart. Characteristics: Begins as the baby’s head enters the birth canal. Woman’s pulse rate increases; sweat appears on her face. Cervix becomes fully dilated and effaced. Crowning occurs, presenting part of baby becomes visible. Delivery is imminent. This stage concludes when the baby is fully delivered. Row 4. Stage of Labor: Third stage. Average Time, Nullipara: 5 to 60 minutes. Average Time, Multipara: 5 to 60 minutes. Frequency of Contractions: Not available. Characteristics: Placental stage. Lasts from delivery of the baby until the placenta has been delivered and the uterus has contracted. Uterine contraction is necessary to squeeze shut all of the tiny blood vessels left exposed when the placenta separates from the uterine wall.

Back to Table

The table shows four columns: Age; Systolic B P in millimeter of mercury; Diastolic B P in millimeter of mercury; and Mean Arterial Pressure in millimeter of mercury, superscript a. Row entries are as follows. Row 1. Birth, 12 hours, less than 1,000 grams; 39 to 59; 16 to 36; 28 to 42. Row 2. Birth, 12 hours, 3 kilograms; 60 to 76; 31 to 45; 48 to 57. Row 3. Neonate, 96 hours; 67 to 84; 35 to 53; 45 to 60. Row 4. Infant, 1 to 12 months; 72 to 104; 37 to 56; 50 to 62. Text for superscript a reads, For practical purposes, approximations may be used, where the goal is for the mean arterial pressure, M A P, to be no lower than the gestational age. For example, a 28-week infant should have a M A P of no lower than 28 millimeters of mercury, a 36-week newborn will have a M A P of no lower than 36 millimeters of mercury, and so on. Abbreviation: B P, blood pressure. Source line reads, Adapted from American Association of Critical-Care Nurses, American Heart Association. P A L S: Vital Signs in Children. Dallas, T X: American Heart Association; 2020.

Back to Table

The table shows two main columns: Sign and Score. Column 2 is further subdivided into three columns: 0, 1, and 2. Row entries are as follows. Row 1. Appearance, color; Blue or pale; Body pink, extremities blue; Completely pink. Row 2. Pulse, heart rate; 0; 0 to 100; greater than 100. Row 3. Grimace, irritability; No response; Grimace; Cries. Row 4. Activity, muscle tone; Limp; Some flexion; Active movement. Row 5. Respirations; Absent; Slow or irregular; Strong cry. Source line reads, Data from Apgar V. A proposal for a new method of evaluation of the newborn infant. Curr Res Anesth Analg. 1953; 32, 4: 260 to 267.

Back to Table

The table shows four columns: Name, Normal, Critically Low, and Critically High. Under Blood Hematology and Coagulation Studies, row entries are as follows. Row 1. Hematocrit, percent volume, neonate; 44 to 64; less than 33; greater than 70. Row 2. Hemoglobin in grams per deciliter, neonate; 14.5 to 22; less than 9.5; greater than 22. Under Chemistry, row entries are as follows. Row 3. Bilirubin in milligrams per deciliter, neonate; 1 to 10; None; greater than 13. Row 4. Glucose in milligrams per deciliter, neonate; 40 to 65; less than 40; greater than 200. Under Microbiology, Qualitative Results, and Serology, row entries are as follows. Row 5. Group B Streptococcus antigen; None; None; Positive, delivery and nursery. Under Urinalysis, row entries are as follows. Row 6. Note exceptions; None; Urine glucose in patient less than 2 years; Positive. Row 7. Note exceptions; None; Urine ketones in patient less than 2 years; Positive. Text below the table reads, Note: There is variance in unpublished lists; this is not an official list.

Back to Table

The table shows five columns: Drug Name, Dose and Route, Concentration, Indications and Comments, and Side Effects. Row entries are as follows. Row 1. Drug Name: Ampicillin. Dose and Route: 50 milligrams per kilogram I V over 5 to 10 minutes. Concentration: No data. Indications and Comments: First-line antibiotic for sepsis workup. Use with gentamicin. Use 100 milligrams per kilogram if meningitis suspected. Side Effects: None. Row 2. Drug Name: Atropine. Dose and Route: 0.01 to 0.03 milligrams per kilogram I V and I M; may repeat every 5 minutes times 3 orally: 2 to 3 times I V dose; minimum dose of 0.1 milligram in infants greater than 5 kilograms. Concentration: No data. Indications and Comments: Preintubation medication to minimize vagal-induced bradycardia. Standard dose of 0.02 milligrams per kilogram used PALS. Side Effects: Tachycardia, arrhythmia, fever, rash, urinary retention. Row 3. Drug Name: Cefotaxime. Dose and Route: 50 milligrams per kilogram I V every 6 to 12 hours depending on weight and age. Concentration: No data. Indications and Comments: Broad-spectrum antibiotic used for suspected and documented gram-negative sepsis. Side Effects: Potential increased risk of fungal infection due to broad spectrum of coverage. Row 4. Drug Name: Ceftriaxone. Dose and Route: 50 milligrams per kilogram per dose I V and I M every 24 hours. Concentration: No data. Indications and Comments: Can be used to complete antibiotic course at home. Do not use in a newborn or a neonate with total bilirubin greater than 5 milligrams per deciliter because it displaces bilirubin from albumin and can lead to kernicterus. Side Effects: Cases of fatal reactions with calcium-ceftriaxone precipitates in lungs and kidneys in both term and premature neonates have been described. Row 5. Drug Name: Dextrose. Dose and Route: 2 milliliters per kilogram I V bolus over 5 to 10 minutes. Concentration: No data. Indications and Comments: Symptomatic hypoglycemia, blood glucose level less than 40 milligrams per deciliter. May use for hydration. May repeat bolus or follow with 5 milligrams per kilogram per minute. Incompatible with blood products. Side Effects: None. Row 6. Drug Name: Dobutamine. Dose and Route: 3 to 5 micrograms per kilogram per minute I V; increase 3 to 10 micrograms per kilogram per minute to maximum 40 micrograms per kilogram per minute. Concentration: No data. Indications and Comments: Cardiogenic shock, hypotension, increased myocardial contractility, cardiac failure. Try volume resuscitation first. Incompatible with sodium bicarbonate. Side Effects: Hypoxemia, tachycardia, arrhythmia. Row 7. Drug Name: Dopamine. Dose and Route: 5 micrograms per kilogram per minute I V; increase 2 to 3 micrograms per kilogram per minute to maximum 40 micrograms kilogram per minute for effect. Concentration: No data. Indications and Comments: Nonhypovolemic shock, increased cardiac output. Try volume resuscitation first. Side Effects: Hypoxemia, tachycardia, arrhythmia. The table shows five columns: Drug Name, Dose and Route, Concentration, Indications and Comments, and Side Effects.

Row entries are as follows. Row 8. Drug Name: Epinephrine. Dose and Route: 0.01 to 0.03 milligrams per kilogram or 0.1 to 0.3 milliliters per kilogram E T or I V every 3 to 5 minutes; may titrate I V dose up to maximum 1 microgram per kilogram per minute for effect. Concentration: No data. Indications and Comments: Resuscitation medication for asystole and bradycardia. Bronchodilator. Standard dose used in PALS and recommended by A A P is 0.01 milligram per kilogram I V. Side Effects: Arrhythmia, hypertension, I V H, renal failure, hypokalemia. Row 9. Drug Name: Gentamicin. Dose and Route: 4 milligrams per kilogram I V and I M, I V preferred, over 30 minutes OR By gestational age: Greater than 35 weeks, 4 milligrams per kilogram 30 to 34 weeks, 4.5 milligrams per kilogram. Concentration: Reconstitute with sterile water: In D 5 W, D 10 W, N S: infuse over 30 minutes. In D 5 W, D 10 W, N S: I V infusion given over 30 to 60 minutes. In D 25 W: dilute to less than 12.5 percent to give via peripheral I V 12.5 micrograms per milliliter; reconstitute in D 5 W, D 10 W and N S, 40 micrograms per milliliter; reconstitute in D 5 W, D 10 W, and N S, 0.1 milligram per milliliter; dilute ratio of 1 to 1 for E T administration. Compatible with T P N, N S, D 5 W, D 10 W. Indications and Comments: Part of sepsis workup. Obtain cultures before administering. Do not give with cephalosporin. Side Effects: None. Row 10. Drug Name: Inhaled nitric oxide. Dose and Route: 20 parts per million starting dose. Concentration: No data. Indications and Comments: Selective decrease in pulmonary vascular resistance. Used for P P H N levels. Started with oxygenation index greater than 25. Needs specific delivery device. Side Effects: Methemoglobinemia: need daily methemoglobin levels. Row 11. Drug Name: Morphine sulfate. Dose and Route: 0.05 to 0.1 milligram per kilogram I M and I V over 15 to 20 minutes, may push over 4 to 5 minutes if needed, then every 4 hours or 10 to 15 micrograms per kilogram per h our infusion. Concentration: Compatible with D 5 W, D 10 W, N S. Indications and Comments: Analgesia and sedation. Do not discontinue suddenly. Do not use in shock and increased intracranial pressure. Use naloxone as antidote for respiratory depression. Side Effects: Respiratory depression, hypotension, bradycardia. The table shows five columns: Drug Name, Dose and Route, Concentration, Indications and Comments, and Side Effects. Row entries are as follows. Row 12. Drug Name: Naloxone hydrochloride. Dose and Route: 0.1 milligram per kilogram I V push and I M; may repeat in 3 to 5 minutes 1.0 milligram per milliliter or 0.4 milligrams per milliliter. Concentration: Compatible with D 5 W and N S. Indications and Comments: Narcotic-induced respiratory depression. Avoid in newborns exposed to maternal narcotic use, may induce withdrawal seizures. Side Effects: Hypertension, arrhythmia, pulmonary edema, vomiting. Row 13. Drug Name: Normal salinevolume expander. Dose and Route: 10 milliliters per kilogram I V; may repeat times 1 if needed. Concentration: Alternatives include whole blood or lactated Ringer solution, 10 milliliters per kilogram. Indications and Comments: First line for volume resuscitation, shock, hypotension, hemorrhage. Side Effects: None. Row 14. Drug Name: Phenobarbital. Dose and Route: 10 to 20 milligrams per kilogram I V, infuse over 10 to 15 minutes; may repeat for continued seizures. Concentration: Compatible with D 5 W, D 10 W, N S. Indications and Comments: Anticonvulsant. First line for seizures. Side Effects: Hypotension, respiratory depression, StevensJohnson syndrome. Row 15. Drug Name: Prostaglandin E 1. Dose and Route: 0.05 micrograms per kilogram per minute infusion; may titrate down when patient is stable, with good effect. Concentration: Compatible with D 5 W, N S; 1 ampule, 500 micrograms plus 500 milliliters I V fluids equals 1 microgram per milliliter P G E solution. Not compatible with other solutions or medications. Indications and Comments: Keeps ductus arteriosus patent. Recommend intubating patient for long transports and obtain second I V access prior to infusion. Side Effects: Apnea, hyperthermia, hypotension, bradycardia, hypoglycemia, seizures, hypocalcemia. Row 16. Drug Name: Sodium bicarbonate. Dose and Route: 2 milli equivalents per kilogram I V push over 2 minutes for resuscitation; repeat as needed. Concentration: 0.5 milli equivalents per milliliter, 4.2 percent solution; also available in 1 milli equivalents per milliliter. Compatible with D 5 W, D 10 W, N S. Indications and Comments: Resuscitation. Metabolic acidosis. Dose in milli equivalent equals base deficit on blood gas times 0.3 times weight in kilogram, over 15 minutes. When the patient has a high serum sodium level, tromethamine, Tham, may be used at a comparable dose to treat metabolic acidosis. Side Effects: Rapid infusion may cause I V H. Text below the table reads, Abbreviations: A A P, American Academy of Pediatrics; D 5 W, 5 percent dextrose in water; D 10 W, 10 percent dextrose in water; D 25 W, 25 percent dextrose in water; E T, endotracheal; I M, intramuscularly; I V H, intraventricular hemorrhage; M I, myocardial infarction; N S, normal saline; PALS, pediatric advanced life support; P G E, prostaglandin E; P P H N, persistent pulmonary hypertension.

Back to Table

The table shows four columns: Category, 0, 1, and 2. Row entries are as follows. Row 1. Face. Disinterested, no expression. Occasional grimace, withdrawn. Frequent frown, clenched jaw. Row 2. Legs. No position or relaxed. Uneasy, restless, tense. Kicking or legs drawn up. Row 3. Activity. Normal position, moves easily. Squirming, tense. Arched, rigid, or jerking. Row 4. Cry. No crying. Moans or whimpers. Cries steadily, screams, or sobs. Row 5. Consolability. Content, relaxed. Distractible. Inconsolable. Text below the table reads, Scores add up and range from 0 to 10.

Back to Table

The table shows two three columns: Activity, Score, and Description. Under head Infants, row entries are as follows. Row 1. Eye opening; 4; Opens spontaneously. Row 2. Eye opening; 3; Opens to speech or sound. Row 3. Eye opening; 2; Opens to pressure. Row 4. Eye opening; 1; No response. Row 5. Verbal; 5; Coos, babbles. Row 6. Verbal; 4; Irritable cry. Row 7. Verbal; 3; Cries to pressure. Row 8. Verbal; 2; Moans to pressure. Row 9. Verbal; 1; No response. Row 10. Motor; 6; Normal spontaneous movement. Row 11. Motor; 5; Withdraws to touch. Row 12. Motor; 4; Withdraws to pressure. Row 13. Motor; 3; Abnormal flexion, decorticate. Row 14. Motor; 2; Abnormal extension, decerebrate. Row 15. Motor; 1; No response, flaccid. Under head Children, the following are listed. Row 1. Eye opening; 4; Opens spontaneously. Row 2. Eye opening; 3; Opens to speech. Row 3. Eye opening; 2; Opens to pressure. Row 4. Eye opening; 1; No response. Row 5. Verbal; 5; Oriented to person, place, and time. Row 6. Verbal; 4; Confused. Row 7. Verbal; 3; Inappropriate words. Row 8. Verbal; 2; Incomprehensible words or sounds. Row 9. Verbal; 1; No response. Row 10. Motor; 6; Obeys verbal commands. Row 11. Motor; 5; Localizes pressure. Row 12. Motor; 4; Withdraws to pressure or displays nonpurposeful movement. Row 13. Motor; 3; Abnormal flexion, decorticate. Row 14. Motor; 2; Abnormal extension, decerebrate. Row 15. Motor; 1; No response, flaccid.

The matrix table shows the comparison for the measurement of height in centimeter with respect to Arm Circumference in centimeter. The data from the table presented in the format arm circumference, height: Predicted Body Weight. Row entries are as follows. Row 1. 150, 34: No data. 150, 36: No data. 150, 38: No data. 150, 40: 103. 150, 42: 110. 150, 44: 116. 150, 46: 123. 150, 48: 129. 150, 50: 136. 150, 52: 143. 150, 54: 149. 150, 56: 156. 150, 58: 162. 150, 60: 169. 150, 62: 175. Row 2. 152, 34: No data. 152, 36: No data. 152, 38: No data. 152, 40: 104. 152, 42: 111. 152, 44: 117. 152, 46: 124. 152, 48: 130. 152, 50: 137. 152, 52: 143. 152, 54: 150. 152, 56: 157. 152, 58: 163. 152, 60: 170. 152, 62: 176. Row 3. 154, 34: No data. 154, 36: No data. 154, 38: No data. 154, 40: 105. 154, 42: 111. 154, 44: 118. 154, 46: 125. 154, 48: 131. 154, 50: 138. 154, 52: 144. 154, 54: 151. 154, 56: 157. 154, 58: 164. 154, 60: 171. 154, 62: 177. Row 4. 156, 34: No data. 156, 36: No data. 156, 38: No data. 156, 40: 106. 156, 42: 112. 156, 44: 119. 156, 46: 125. 156, 48: 132. 156, 50: 139. 156, 52: 145. 156, 54: 152. 156, 56: 158. 156, 58: 165. 156, 60: 171. 156, 62: 178. Row 5. 158, 34: No data. 158, 36: No data. 158, 38: No data. 158, 40: 107. 158, 42: 113. 158, 44: 120. 158, 46: 126. 158, 48: 133. 158, 50: 139. 158, 52: 146. 158, 54: 153. 158, 56: 159. 158, 58: 166. 158, 60: 172. 158, 62: 179. Row 6. 160, 34: No data. 160, 36: No data. 160, 38: 101. 160, 40: 107. 160, 42: 114. 160, 44: 121. 160, 46: 127. 160, 48: 134. 160, 50: 140. 160, 52: 147. 160, 54: 153. 160, 56: 160. 160, 58: 167. 160, 60: 173.

160, 62: 180. Row 7. 162, 34: No data. 162, 36: No data. 162, 38: 101. 162, 40: 108. 162, 42: 115. 162, 44: 121. 162, 46: 128. 162, 48: 135. 162, 50: 141. 162, 52: 148. 162, 54: 154. 162, 56: 161. 162, 58: 167. 162, 60: 174. 162, 62: 181. Row 8. 164, 34: No data. 164, 36: No data. 164, 38: 102. 164, 40: 109. 164, 42: 116. 164, 44: 122. 164, 46: 129. 164, 48: 135. 164, 50: 142. 164, 52: 149. 164, 54: 155. 164, 56: 162. 164, 58: 168. 164, 60: 175. 164, 62: 182. Row 9. 166, 34: No data. 166, 36: No data. 166, 38: 103. 166, 40: 109. 166, 42: 117. 166, 44: 123. 166, 46: 130. 166, 48: 136. 166, 50: 143. 166, 52: 149. 166, 54: 156. 166, 56: 163. 166, 58: 169. 166, 60: 176. 166, 62: 182. Row 10. 168, 34: No data. 168, 36: No data. 168, 38: 104. 168, 40: 110. 168, 42: 117. 168, 44: 124. 168, 46: 131. 168, 48: 137. 168, 50: 144. 168, 52: 150. 168, 54: 157. 168, 56: 163. 168, 58: 170. 168, 60: 177. 168, 62: 183. Row 11. 170, 34: No data. 170, 36: No data. 170, 38: 105. 170, 40: 111. 170, 42: 118. 170, 44: 125. 170, 46: 131. 170, 48: 138. 170, 50: 145. 170, 52: 151. 170, 54: 158. 170, 56: 164. 170, 58: 171. 170, 60: 178. 170, 62: 184. Row12. 172, 34: No data. 172, 36: No data. 172, 38: 106. 172, 40: 112. 172, 42: 119. 172, 44: 126. 172, 46: 132. 172, 48: 139. 172, 50: 145. 172, 52: 152. 172, 54: 159. 172, 56: 165. 172, 58: 172. 172, 60: 178. 172, 62: 185. Row 13. 174, 34: No data. 174, 36: 100. 174, 38: 107. 174, 40: 113. 174, 42: 119. 174, 44: 127. 174, 46: 133. 174, 48: 140. 174, 50: 146. 174, 52: 153. 174, 54: 159. 174, 56: 166. 174, 58: 173. 174, 60: 179. 174, 62: 186. Row 14. 176, 34: No data. 176, 36: 101. 176, 38:108. 176, 40: 114. 176, 42: 120. 176, 44: 127. 176, 46: 134. 176, 48: 141. 176, 50: 147. 176, 52: 154. 176, 54: 160. 176, 56: 167. 176, 58: 174. 176, 60: 180. 176, 62: 187. Row 15. 178, 34: No data. 178, 36: 101. 178, 38: 109. 178, 40: 115. 178, 42: 121. 178, 44: 128. 178, 46: 135. 178, 48: 141. 178, 50: 148. 178, 52: 155. 178, 54: 161. 178, 56: 168. 178, 58: 174. 178, 60: 181. 178, 62: 188. Row 16. 180, 34: No data. 180, 36: 102. 180, 38: 109. 180, 40: 116. 180, 42: 122. 180, 44: 129. 180, 46: 136. 180, 48: 142. 180, 50: 149. 180, 52: 155. 180, 54: 162. 180, 56: 169. 180, 58: 175. 180, 60: 182. 180, 62: 188.
